Role of Imprint Cytology in Diagnosis of Thyroid Lesions

Abilash K Prasad¹, Chellaiah Petchiappan Ganesh Babu², Chetan Anand³, Kathirvelu Shanmugasamy⁴

ABSTRACT

Background: Thyroid disorders are common in India. Rapid and accurate intraoperative diagnosis of thyroid lesions helps in deciding the plan of management and spares the patient the additional expenses and morbidity of a second surgery.

Aim: To assess the role of imprint cytology in the diagnosis of thyroid lesions in consecutive thyroidectomy specimens. A cross-sectional study was done at the Mahatma Gandhi Medical College and Research Institute, Puducherry. The study period was between November 2015 and July 2017 during which 60 consecutive thyroidectomy specimens were subjected to touch imprint cytology by the same pathologist who was blinded of the prior fine needle aspiration cytology reports, and the results of imprint cytology and fine needle aspiration cytology were compared with the final histopathological examination report. The data obtained were entered in MS Excel sheet and analyzed.

Results: A total of 60 consecutive thyroid specimens from the Departments of General Surgery and ENT were studied. Imprint cytology had a sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of 61.5%, 97.9%, 88.8%, 90.1%, and 90%, respectively, which was found to be better compared to fine needle aspiration cytology.

Conclusion: Imprint cytology is a simple, cheap, and reliable intraoperative diagnostic technique for thyroid lesions. It has high specificity, positive predictive value, negative predictive value, and accuracy. The lack of uniform availability and expense remains a limiting factor for the frozen section. The diagnostic indices of imprint cytology were found to be comparable to that of frozen section in various other studies.

Keywords: Cytology, Imprint cytology, Thyroid.

World Journal of Endocrine Surgery (2019): 10.5005/jp-journals-10002-1260

INTRODUCTION

Thyroid disorders are a common entity throughout the world including in India. Though fine needle aspiration cytology (FNAC) has been in use since the early 1950s, the diagnostic accuracy varies in different studies and there are certain diagnostic pitfalls associated, and the search has been on for a cytological method with better accuracy. Intraoperative diagnosis in the form of frozen section has been used in various centers but many centers lack the facility and expertise for frozen section which is also time-consuming and expensive. Imprint cytology offers a simpler and cheaper alternative. There are not many studies conducted regarding the accuracy of imprint cytology in thyroid lesions in India. Hence, this study was conducted with the aim of assessing the role of imprint cytology in diagnosing thyroid lesions keeping histopathological examination (HPE) as the gold standard.

AIMS AND OBJECTIVES

• Aim—to assess the role of imprint cytology in the diagnosis of thyroid lesions
• Objective—to compare imprint cytology and fine needle aspiration cytology with histopathological examination in the diagnosis of thyroid lesions

METHODOLOGY

This was a cross-sectional study, which was conducted at a tertiary care hospital over a period of one and a half years after the approval of the Institutional Medical Ethics Committee. Consecutive thyroidectomies cases were considered for the study. Sixty sequential patients undergoing thyroidectomy at the institution were included in the study. Fine needle aspiration cytology of the thyroid lesion was done. Fresh thyroidectomy specimens were fixed in formaldehyde. Tissue sample was taken from the operation theatre before fixation in formalin to the pathologist. Five to six imprint slides were made by gently pressing clean glass slides over the lesional areas of the submitted thyroid tissue. The slides were immediately submerged in 95% ethanol in a Koplin jar. The slides were then stained with rapid H&E staining method. The same pathologist who was blinded of the fine needle aspiration cytology report examined the slides of all the patients and reported the imprint cytology on the same day before the HPE report. The histopathological examination report was given by a different pathologist who was blinded of the fine needle aspiration cytology and imprint cytology reports. Imprint cytology report was then compared with fine needle aspiration cytology and histopathological examination reports (Figs 1 and 2).

RESULTS

Of the malignant lesions, papillary carcinoma accounted for the maximum number of lesions. Colloid goiter accounted for...
the highest number of benign lesions accounting for 43.3% of the cases. There were 4 cases of follicular variant of papillary carcinoma and one case of papillary carcinoma with metastasis. There was one case of medullary carcinoma of the thyroid (Table 1).

Role of Fine Needle Aspiration Cytology
The results of preoperative FNAC were compared with the final HPE diagnosis. This included both reports of FNAC done within the institute as well as the reports brought by the patients of FNAC done at outside centers (Table 2).

The sensitivity and specificity for FNAC were found to be 46.2% and 97.9% in this study. The positive predictive value was 85.7% and the negative predictive value was found to be 86.8%. The accuracy rate for FNAC was found to be 86.6%.

Role of Imprint
The results of imprint cytology were compared to the final HPE results. Of the 13 malignant lesions in the study, imprint cytology was able to accurately diagnose 8 of the lesions to be malignant accounting for 61.5%. Of the 47 benign cases, imprint cytology accurately diagnosed these to be benign in 46 cases (Table 3).

In this study, imprint cytology was found to have a sensitivity and specificity of 61.5% and 97.9%. The positive predictive value and negative predictive value were found to be 88.8% and 90.1%, respectively. The overall accuracy of imprint cytology was 90% (Table 4).

Diagnostic Indices of FNAC
The sensitivity and overall accuracy of FNAC at 46.2% and 86.6% is found to be lesser compared to other studies. However, the specificity, positive predictive value, and negative predictive values are comparable (Table 5).

Diagnostic Indices of Imprint Cytology
In the current study, the sensitivity, specificity, positive predictive value, negative predictive value, and accuracy were 61.5%, 97.9%, 88.8%, 90.1%, and 90%, respectively. There have not been many studies conducted in India regarding imprint cytology. In one of the largest studies on imprint cytology conducted in India at the Department of Pathology at the Regional Cancer Centre, Trivandrum, by Anila and Krishna, which included 84 patients, the sensitivity, specificity, positive predictive value, and negative predictive value were 75%, 100%, 100%, and 98.7%, respectively. The sensitivity was found to be lower in our study compared to other studies but the other diagnostic indices have been found to be comparable and better compared to FNAC. The sensitivity of imprint cytology was found to be 61.5% in our study compared to 80% in the study conducted by Ahmadinejad et al., 75% in the study conducted by Anila and Krishna, and 83.3% in the study conducted by Taneri et al.4,6,8 The nuclear features were much clearer in imprint cytology. In studies such as those by Rupp and Ehya,9 the particular
importance of nuclear grooving in identifying papillary carcinoma as well as the advantage of using imprint cytology in assessing this feature has been well emphasized. In the current study, intraoperative imprint cytology also provided the pathologist with an opportunity to assess the gross features of the thyroid specimen which were not possible with FNAC and proved to be quite valuable. One of the drawbacks of imprint cytology found in our study has been the difficulty in accurately diagnosing follicular variants of papillary carcinoma. Imprint has been accurately used to diagnose medullary carcinoma; however, the statistical significance is questionable since there is only one case of medullary carcinoma in the present study (Table 6).

On reviewing the literature, it was also found that the overall accuracy of imprint cytology in our study was similar to those of frozen section in several studies of thyroid lesions proving that imprint cytology could prove to be an invaluable alternative for intraoperative diagnosis of thyroid lesions in centers with the lack of frozen section.

**Table 2:** Comparison between preoperative FNAC report and postoperative histopathology examination of study participants

| Malignant status | Preop FNAC | Postoperative HPE |
|------------------|------------|-------------------|
|                   | Malignant  | Benign            |
|                   | 6 (46.2)   | 1 (2.1)           |
|                   | 7 (53.8)   | 46 (97.9)         |
| Total             | 13 (100)   | 53 (88.3)         |

**Table 3:** Comparison between intraoperative imprint cytology result and postoperative histopathology examination of study participants

| Malignant status | Imprint cytology | Postoperative HPE |
|------------------|------------------|-------------------|
|                  | Malignant        | Benign            |
|                  | 8 (61.5)         | 1 (2.1)           |
|                  | 5 (38.5)         | 46 (97.9)         |
| Total            | 13 (100)         | 51 (85)           |

**Table 4:** Diagnostic indices of preoperative FNAC and imprint cytology to diagnose malignant lesions of thyroid

| S. no. | Indices of screening test | FNAC | Imprint cytology |
|--------|---------------------------|------|------------------|
| 1      | Sensitivity               | 46.2 | 61.5             |
| 2      | Specificity               | 97.9 | 97.9             |
| 3      | Positive predictive value | 85.7 | 88.8             |
| 4      | Negative predictive value | 86.8 | 90.1             |
| 5      | False benign rate         | 53.8 | 38.4             |
| 6      | False malignant rate      | 2.1  | 2.1              |
| 7      | Accuracy                  | 86.6 | 90               |

**Table 5:** Comparison of diagnostic indices of FNAC with other studies

|                  | Present study | Hajmanoochehri and Rabiee¹ | Ozdemir et al.² | Bagga and Mahajan³ | Ahmadinejad et al.⁴ | Jyothi et al.⁵ |
|------------------|---------------|---------------------------|-----------------|---------------------|---------------------|---------------|
| Sensitivity      | 46.2          | 95.2                      | 78.5            | 66                  | 62.5                | 66.7          |
| Specificity      | 97.9          | 68.4                      | 97              | 100                 | 100                 | 98.9          |
| Positive predictive value | 85.7          | 83.3                      | 72.6            | –                   | 100                 | 88.9          |
| Negative predictive value | 86.8          | 89.6                      | 97.8            | –                   | 95.3                | 96            |
| Accuracy         | 86.6          | 85.1                      | 95.3            | 96.2                | –                   | 95.4          |

**Conclusion**

Based on our study, we have come to the following conclusions. Colloid goitre was the most common benign lesion and papillary carcinoma was the most common malignancy accounting for 43.3 and 18.3% of the study population. Imprint cytology had a sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of 61.5%, 97.9%, 88.8%, 90.1%, and 90%, respectively, which was found to be better compared to FNAC. The diagnostic accuracy of imprint cytology in the present study was found to be similar to that of frozen section in various other studies proving imprint cytology could be a valuable alternative to frozen section (Table 7).

**Limitations**

The diagnostic accuracy of imprint cytology was compared with that of frozen section in other studies. Including frozen section in the current study would have produced a better comparison. Also there has been only a single case of medullary carcinoma.
in our study. So the diagnostic accuracy of imprint cytology in medullary carcinoma needs to be evaluated further.
