AUTOMORPHISMS OF MODULI SPACES OF SYMPLECTIC BUNDLES

INDRANIL BISWAS, TOMÁS L. GÓMEZ, AND VICENTE MUÑOZ

Abstract. Let $X$ be an irreducible smooth complex projective curve of genus $g \geq 3$. Fix a line bundle $L$ on $X$. Let $M_{Sp}(L)$ be the moduli space of symplectic bundles $(E, \varphi : E \otimes E \to L)$ on $X$, with the symplectic form taking values in $L$. We show that the automorphism group of $M_{Sp}(L)$ is generated by automorphisms of the form $E \mapsto E \otimes M$, where $M \cong \mathcal{O}_X$, and automorphisms induced by automorphisms of $X$.

1. Introduction

Let $X$ be a smooth complex projective curve of genus $g$, with $g \geq 3$. A set of generators of the automorphism group of the moduli space of semistable vector bundles over $X$ of rank $r$ with fixed determinant $L$ was obtained by Kouvidakis and Panetov in [KP]. More precisely, they proved that the automorphism group is generated by the automorphisms of $X$, automorphisms of the form $E \mapsto E \otimes M$, where $M$ is a line bundle with $M \otimes 2 \cong \mathcal{O}_X$, and, if $r$ divides $2 \deg L$, automorphisms of the form $E \mapsto E^\vee \otimes N$, where $N$ is a line bundle with $N \otimes r \cong L \otimes 2$. In the same paper they prove a Torelli theorem for these moduli spaces. The proofs of their results crucially use the Hitchin map defined on the moduli of Higgs bundles. In [HR], Hwang and Ramanan gave a different proof of the above results using Hecke curves, which are minimal rational curves constructed using Hecke transformations.

Fix a holomorphic line bundle $L$ on $X$, and consider the moduli space $M_{Sp}(L)$ of stable symplectic bundles $(E, \varphi : E \otimes E \to L)$ of rank $2n$ and with values in $L$. Take a line bundle $M$ on $X$ with $M \otimes 2 \cong \mathcal{O}_X$. Fix an isomorphism $\beta : M \otimes 2 \to \mathcal{O}_X$. Then we have an automorphism of $M_{Sp}(L)$ defined by $(E, \varphi) \mapsto (E \otimes M, \varphi \otimes \beta)$.

More generally, let $\sigma : X \to X$ be an automorphism, and let $M$ be a line bundle on $X$ such that $M \otimes 2 \cong L \otimes (\sigma^* L)^\vee$. Fix an isomorphism $\beta$ as above. Then $(E, \varphi) \mapsto (M \otimes \sigma^* E, \beta \otimes \sigma^* \varphi)$ is an automorphism of $M_{Sp}(L)$. We remark that, in both cases, the automorphism does not depend on the choice of $\beta$.

In Theorem 6.5 we show that these are all the automorphisms of $M_{Sp}(L)$. More precisely, the automorphism group $\text{Aut}(M_{Sp}(L))$ fits in a short exact sequence of groups

$$e \to J(X)_2 \to \text{Aut}(M_{Sp}(L)) \to \text{Aut}(X) \to e,$$

where $J(X)_2$ is the group of line bundles on $X$ of order two (see Proposition 6.7). Since the above mentioned automorphisms of $M_{Sp}(L)$ extend to the moduli space of semistable symplectic bundles, it follows that $\text{Aut}(M_{Sp}(L))$ coincides with the automorphism group of the moduli space of semistable symplectic bundles (see Lemma 6.8).

We also prove a Torelli type theorem for this moduli space (Theorem 4.3). This was proved earlier in [BH] by a different method.

2000 Mathematics Subject Classification. 14H60.
Let us comment on our method of proof. The computation in [KP] of the automorphism group of the moduli space of vector bundles uses a delicate argument in which the fibers of the Hitchin map are studied over singular curves with non-generic singularities. Such argument is not easy to generalize to other groups (like the symplectic group). The proof of [HR] is simpler in spirit: it determines geometrically the Hitchin discriminant (the locus of singular spectral curves), and then uses the theory of minimal rational curves to prove that the dual variety of this Hitchin discriminant is a locus of Hecke transforms. Neither of the theory of minimal rational curves nor the constructions of Hecke transforms can be generalized to other groups to an extent that cover the arguments.

We were lead to take the proof of [HR] for the automorphism group of the moduli space of vector bundles and simplify it by removing the use of the dual varieties. Actually, we found that the Hitchin discriminant is enough to recover the nilpotent cones, and from this to get the automorphism group. Therefore, the proof given in this paper is the extension to the case of the moduli space of symplectic vector bundles of a proof for the moduli space of vector bundles which is not in the literature, and which simplifies both [KP] and [HR].

2. Moduli space of symplectic bundles

Let
\[ J = \begin{pmatrix} 0_{n \times n} & I_{n \times n} \\ -I_{n \times n} & 0_{n \times n} \end{pmatrix} \]
be the standard symplectic form on \( \mathbb{C}^{2n} \). Define the group
\[ \text{Gp}(2n, \mathbb{C}) = \{ A \in \text{GL}(2n, \mathbb{C}) : A^t J A = cJ \text{ for some } c \in \mathbb{C}^* \} . \]
It is an extension of \( \mathbb{C}^* \) by the symplectic group \( \text{Sp}(2n, \mathbb{C}) \)
\[ e \longrightarrow \text{Sp}(2n, \mathbb{C}) \longrightarrow \text{Gp}(2n, \mathbb{C}) \xrightarrow{q} \mathbb{C}^* \longrightarrow e, \]
where \( q(A) = c \) for any \( A \) and \( c \) as in (2.1). From the definition of the homomorphism \( q \) it follows immediately that for all \( A \in \text{Gp}(2n, \mathbb{C}) \),
\[ \det A = q(A)^n. \]

Let \( X \) be an irreducible smooth complex projective curve of genus \( g \), with \( g \geq 3 \). A symplectic bundle on \( X \) of rank \( 2n \) with values in a holomorphic line bundle \( L \) is a pair \((E, \varphi)\), where \( E \) is a holomorphic vector bundle of rank \( 2n \) and \( \varphi : E \wedge E \longrightarrow L \) is a homomorphism of coherent sheaves which is fiberwise nondegenerate. The line bundle \( \det(E) \) is canonically a direct summand of \( (E \wedge E)^\otimes n \), and the composition
\[ \det(E) \hookrightarrow (E \wedge E)^\otimes n \xrightarrow{\varphi^\otimes n} L^\otimes n \]
is an isomorphism. Giving a symplectic bundle is equivalent to giving a principal \( \text{Gp}(2n, \mathbb{C}) \)-bundle.

Let \((E, \varphi)\) be a symplectic bundle. A holomorphic subbundle \( F \) of \( E \) is called isotropic if \( \varphi(F \wedge F) = 0 \).

A symplectic bundle \((E, \varphi)\) is called stable (respectively, semistable) if, for all isotropic proper subbundles \( E' \subset E \) of positive rank,
\[ \frac{\deg E'}{\text{rk } E'} < \frac{\deg E}{\text{rk } E} \quad (\text{respectively, } \frac{\deg E'}{\text{rk } E'} \leq \frac{\deg E}{\text{rk } E}) \]

is an isomorphism. Giving a symplectic bundle is equivalent to giving a principal \( \text{Gp}(2n, \mathbb{C}) \)-bundle.
See [BG] for more on symplectic bundles.

We denote by $M_{\text{Sp}}(L)$ the moduli space of stable symplectic bundles with values in a fixed line bundle $L$.

**Lemma 2.1.** Assume that $\deg L \leq 2(g-1)$. Then $H^0(E) = 0$ for a general stable bundle $(E, \varphi) \in M_{\text{Sp}}(L)$.

**Proof.** Using Riemann–Roch, $\dim M_{\text{Sp}}(L) = n(2n+1)(g-1)$. By semicontinuity,
$$\{(E, \varphi) \in M_{\text{Sp}}(L) \mid H^0(E) \neq 0\} \subset M_{\text{Sp}}(L)$$
is a Zariski closed subset. The lemma will be proved by showing that the codimension of this subset is positive.

Take a pair $((E, \varphi), s)$ such that $(E, \varphi) \in M_{\text{Sp}}(L)$ and $s \in H^0(E) \setminus \{0\}$. It defines a short exact sequence
$$0 \to M = \mathcal{O}_X(D) \xrightarrow{s} E \to Q \to 0,$$
where $D$ is the effective divisor defined by $s$. Let $K$ be the kernel of the composition
$$E \xrightarrow{\varphi} E^\vee \otimes L \to M^\vee \otimes L.$$
Define $Q := E/M$. Since $\varphi(M \otimes K) = 0$, it follows that $\varphi$ defines a pairing
$$Q \otimes K \to L.$$

This pairing is perfect because $\varphi$ is pointwise nondegenerate. In particular, $Q \cong K^\vee \otimes L$. We have a diagram
$$\begin{array}{cccccc}
0 & 0 \\
\downarrow & \downarrow \\
0 & \to & M & \to & K & \to & F & \to & 0 \\
\| & \\
0 & \to & M & \to & E & \to & Q & \to & 0 \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \\
M^\vee \otimes L & = & M^\vee \otimes L & \\
0 & 0 & 0 & \\
\end{array}$$
and there is a symplectic form $\omega_F : F \otimes F \to L$ induced by $\varphi$ (recall that $\varphi(M \otimes K) = 0$).

Note that under the homomorphism
$$\text{Ext}^1(Q, M) \to \text{Ext}^1(F, M) = \text{Ext}^1(M^\vee \otimes L, F),$$
the class $\xi_1 \in \text{Ext}^1(Q, M)$ for the bottom exact sequence in (2.4) maps to the class $\xi_2 \in \text{Ext}^1(M^\vee \otimes L, F)$ for the vertical exact sequence in the right of (2.4). For a general point $(E', \varphi') \in M_{\text{Sp}}(L)$, the underlying vector bundle $E'$ is stable. If $E$ is a stable vector bundle, then $\text{Hom}(Q, M) = 0$, because any nonzero homomorphism from $Q$ to $M$ produces a nilpotent endomorphism of $E$.

Let $\deg M = \ell$ and $\deg E = n \cdot \deg L = d$. If $\text{Hom}(Q, M) = 0$, then
$$\dim \text{Ext}^1(Q, M) = -\deg(Q^\vee \otimes M) + (2n-1)(g-1) = d - 2n\ell + (2n-1)(g-1).$$

Now let us see that the symplectic form $\omega_F : F \otimes F \to L$ determines the symplectic form on $E$. First, $\omega_F$ extends uniquely to a homomorphism $F \otimes K \to L$, which extends naturally to a homomorphism $Q \otimes K \to L$; both these extensions
are consequences of the fact that \( \varphi(M \otimes K) = 0 \). Any two extensions of the pairing \( F \otimes K \to L \) to a pairing \( Q \otimes K \to L \) differ by a section contained in \( \text{Hom}((Q/F) \otimes K, L) = \text{Hom}((M^\vee \otimes L) \otimes K, L) = \text{Hom}(K, M) \).

We will show that

\begin{equation}
\text{Hom}(K, M) = 0.
\end{equation}

First, if a homomorphism \( K \to M \) composed with \( M \to K \) is non-zero, then it produces a splitting of the short exact sequence

\[ 0 \to M \to K \to F \to 0. \]

So the extension \( F \to Q \to M^\vee \otimes L \) is split. Therefore there are maps \( Q \to F \) and \( F \to K \), which composed with \( K \to E \) splits the diagram \( Q \to F \), but this is not possible since \( E \) is stable. So the homomorphism \( K \to M \) composed with \( M \to K \) is the zero homomorphism. But then the homomorphism \( K \to M \) descends to a homomorphism \( F \to M \). Let \( S_1 \) (respectively, \( S_2 \)) be the kernel of \( K \to M \) (respectively, of \( F \to M \)). Then there is an exact sequence

\[ 0 \to M \to S_1 \to S_2 \to 0. \]

So it follows that \( \deg F \leq \deg S_1 \). As \( S_1 \subset K \subset E \), and \( E \) is a stable bundle, then \( \mu(S_1) < \mu(E) \). So

\[ \frac{\deg L}{2} = \mu(F) \leq \mu(S_1) < \mu(E) = \frac{\deg L}{2}, \]

which is a contradiction. Therefore, (2.6) is proved.

Now the homomorphism \( Q \otimes K \to L \) extends uniquely to a map \( E \otimes K \to L \). This again extends to the map \( \omega_E : E \otimes E \to L \), up to an indeterminacy contained in \( \text{Hom}(E \otimes (E/K), L) = \text{Hom}(E \otimes (M^\vee \otimes L), L) \), which actually lives in the subspace \( \text{Hom}((E/M) \otimes (M^\vee \otimes L), L) = \text{Hom}(Q, M) = 0 \).

Then the dimension of the family of bundles parametrizing (2.3) is

\[ (2n-1)(n-1)(g-1) + d - 2n\ell + (2n-1)(g-1) - 1 \]

\[ \leq (2n+1)n(g-1) + d - 2n(g-1) - 1 < (2n+1)n(g-1), \]

for \( d \leq 2n(g-1) \). This completes the proof of the lemma. \( \square \)

For a symplectic bundle \((E, \varphi)\), let

\[ \text{End}_{\text{sp}}(E) := \text{Sym}^2(E) \otimes L^\vee \subset \text{End}(E) = E \otimes E \otimes L^\vee \]

be the set consisting of symmetric symplectic endomorphisms of \( E \). For any divisor \( D \) on \( X \), define

\[ \text{End}_{\text{sp}}(E)(D) := \text{End}_{\text{sp}}(E) \otimes_{\mathcal{O}_X} \mathcal{O}_X(D). \]

**Lemma 2.2.** Let \( D \) be an effective divisor of degree \( \ell \), with \( g \geq \max\{2\ell, \ell + 2\} \). Then \( H^0(\text{End}_{\text{sp}}(E)(D)) = 0 \) for a general stable symplectic bundle \((E, \varphi) \in M_{\text{sp}}(L)\).

**Proof.** By tensoring with a suitable line bundle, we may assume that \( L \) has degree \( \epsilon \in \{0,1\} \). This makes the slope of any symplectic bundle to be \( \frac{\ell}{2} < g-1 \).

Moreover, we may assume that \( L \) is generic in the sense that

\[ H^0(L(D)) = 0 \quad \text{and} \quad H^0(L^*(D)) = 0, \]

for any \( D \) effective divisor of degree \( \ell \leq g-1-\epsilon \). Let \( X(\ell) = \text{Sym}^\ell(X) \) be the set of effective divisors of degree \( \ell \).
For \( n = 1 \), consider any stable vector bundle \( F \) of rank two with determinant \( L \). It has a symplectic structure:
\[
\omega : F \otimes F \to \wedge^2 F = L.
\]
The symplectic bundle \((F, \omega)\) is automatically stable. However, we are going to construct an specific bundle \( F_0 \) for later use. Consider an extension
\[
(2.7) \quad 0 \to \mathcal{O}_X \to F_0 \to L \to 0.
\]
These extensions are parametrized by elements in \( H^1(L^*) \), and \( \dim H^1(L^*) = g - 1 + \epsilon \). Consider an effective divisor \( D \in X^{(\ell)} \). Then the exact sequence
\[
0 \to L^* \to L^*(D) \to L^*(D)|_D \to 0
\]
gives an exact sequence
\[
0 \to L^*(D)|_D \to H^1(L^*) \to H^1(L^*(D)) \to 0,
\]
so we get a subspace \( V_D := L^*(D)|_D \subset H^1(L^*) \) of dimension \( \ell \). Moving \( D \) over \( X^{(\ell)} \), we see that if \( g - 1 + \epsilon > 2\ell \), then there is an extension \((2.7)\) whose class \( \xi \in H^1(L^*) \) goes to a non-zero element under the homomorphism \( H^1(L^*) \to H^1(L^*(D)) \) for any \( D \in X^{(\ell)} \). Now the connecting homomorphism \( H^0(\mathcal{O}_X(D)) \to H^1(L^*(D)) \) for the dual sequence
\[
(2.8) \quad 0 \to L^*(D) \to F_0^*(D) \to \mathcal{O}_X(D) \to 0
\]
of \((2.7)\), which is multiplication by \( \xi \), is injective; indeed, if a section \( s \in H^0(\mathcal{O}_X(D)) \), defining a divisor \( D' \), maps to zero, then the extension class \( \xi \) goes to zero under the homomorphism \( H^1(L^*) \to H^1(L^*(D')) \), but this is not the case by construction. This implies that
\[
H^0(L^*(D)) = H^0(L^* \otimes F_0(D)),
\]
which is zero by assumption. Also the exact sequence
\[
0 \to H^0(\mathcal{O}_X(D)) \to H^0(F_0(D)) \to H^0(L(D)) = 0
\]
implies that \( H^0(F_0(D)) = H^0(\mathcal{O}_X(D)) \). And finally, the exact sequence
\[
\text{Hom}(L, F_0(D)) = 0 \to \text{Hom}(F_0, F_0(D)) \to \text{Hom}(\mathcal{O}_X, F_0(D)) = H^0(\mathcal{O}_X(D))
\]
gives that \( H^0(\text{End} F_0(D)) = H^0(\mathcal{O}_X(D)) \). Hence \( H^0(\text{End}_0 F_0(D)) = 0 \), where \( \text{End}_0 \) denotes the space of trace-free endomorphisms. Note that \( \text{End}_{Sp} F_0 = \text{End}_0 F_0 \), so \( H^0(\text{End}_{Sp} F_0(D)) = 0 \).

Now for \( n > 1 \), consider a general symplectic bundle \((F_1, \omega_1)\) of rank \( 2n - 2 \). By induction hypothesis, \( H^0(\text{End}_{Sp} F_1(D)) = 0 \), for any effective divisor \( D \) of degree \( \ell \). Consider the symplectic bundle \( E = F_0 \oplus F_1 \). This is a symplectic semistable bundle of rank \( 2n \). Let us see that
\[
(2.9) \quad H^0(\text{End}_{Sp} E(D)) = 0.
\]
This would imply that also for a general stable bundle \( \tilde{E} \), we have that
\[
H^0(\text{End}_{Sp} \tilde{E}(D)) = 0
\]
for all \( D \in X^{(\ell)} \) (note that \( X^{(\ell)} \) is a complete variety).

The vector space \( H^0(\text{End}_{Sp} E(D)) \) has four components:
- \( H^0(\text{End}_{Sp} F_0(D)) = 0 \), by construction.
- \( H^0(\text{End}_{Sp} F_1(D)) = 0 \), by induction hypothesis.
• \( H^0(\text{Hom}_\mathbb{P}(F_0, F_1(D))) = 0 \). A homomorphism \( \varphi : F_0 \to F_1(D) \) can be restricted to \( \mathcal{O} \subset F_0 \), so it defines a section in \( H^0(F_1(D)) \). By Lemma 2.1, this is zero (as \( \mu(F_1(D)) = \frac{k}{2} + \ell < g - 1 \)). So \( \varphi \) defines a section of the quotient \( L \to F_1(D) \), i.e., a section of \( H^0(L^* \otimes F_1(D)) \), which is also zero (\( L \) is fixed, so can take both \( F_1 \) and \( F_1 \otimes L^* \) to be simultaneously generic).

• \( H^0(\text{Hom}_\mathbb{P}(F_1, F_0(D))) = 0 \). A homomorphism \( \varphi : F_1 \to F_0(D) \) gives a homomorphism \( F_0^\vee = F_0 \otimes L^{-1} \to F_1^\vee(D) = F_1 \otimes L^{-1}(D) \), i.e., a symplectic map \( F_0 \to F_1(D) \), which is zero as above.

This completes the proof of the lemma.

3. Hitchin discriminant

Let us recall the definition of the Hitchin map (see [Hi, Section 5.10]). The holomorphic cotangent bundle of \( X \) will be denoted by \( \mathcal{K}_X \). A symplectic Higgs bundle is a triple \((E, \omega, \theta)\), where \((E, \omega)\) is a symplectic bundle and \( \theta : E \to E \otimes \mathcal{K}_X \) is a symmetric map with respect to \( \omega \):

\[
\omega(u, \theta(v)) = -\omega(\theta(u), v)
\]

for \( u, v \in E_x \), \( x \in X \).

Let \( \mathcal{M}_{\text{Sp}}(L) \) be the moduli space of semistable symplectic Higgs bundles of rank \( 2n \).

As before, \( \mathcal{M}_{\text{Sp}}(L) \) is the moduli space of stable symplectic bundles. The cotangent bundle \( T^*\mathcal{M}_{\text{Sp}}(L) \subset \mathcal{M}_{\text{Sp}}(L) \) is an open subset. Consider the affine space:

\[
W = H^0(K_X^2) \oplus \ldots \oplus H^0(K_X^{2n}),
\]

and the Hitchin map on \( T^*\mathcal{M}_{\text{Sp}}(L) \)

\[
h : T^*\mathcal{M}_{\text{Sp}}(L) \to W,
\]

defined by \( h(\theta) = (s_2(\theta), \ldots, s_{2n}(\theta)) \), where \( s_i(\theta) = \text{tr}(\wedge^i \theta) \), and

\[
\theta \in T^*_{E}\mathcal{M}_{\text{Sp}}(L) = H^0(\text{End}_{\text{Sp}}(E) \otimes \mathcal{K}_X).
\]

This extends to the Hitchin map on the moduli space \( \mathcal{M}_{\text{Sp}}(L) \) of semistable symplectic Higgs bundles,

\[
H : \mathcal{M}_{\text{Sp}}(L) \to W.
\]

For an element \( s = (s_2, \ldots, s_{2n}) \in W \), the spectral curve \( X_s \) associated to \( s \) is the curve in the total space \( \mathcal{V}(K_X) \) of \( K_X \) defined by the equation

\[
y^{2n} + s_2(x)y^{2n-2} + \ldots + s_{2n-2}(x)y^2 + s_{2n}(x) = 0
\]

(\( x \) is a coordinate for \( X \), and \( y \) is the corresponding tautological coordinate \( dx \) along the fibers of the projection \( \mathcal{V}(K_X) \to X \)).

Consider the compactification

\[
S := \mathbb{P}(\mathcal{O}_X \oplus K_X) \subset \mathcal{V}(K_X).
\]

Let \( p : S \to X \) be the projection. Giving a Higgs bundle \((E, \theta : E \to E \otimes K_X)\) is equivalent to giving a coherent sheaf \( A \) of rank one supported on some spectral curve \( S \subset \mathcal{V}(K_X) \). Indeed, \( E = p_*A \), and the Higgs field \( \theta \) corresponds to the homomorphism \( A \to A \otimes p^*K_X \) defined by multiplication with the tautological section of \( p^*K_X \) over \( \mathcal{V}(K_X) \) (recall that \( S \subset \mathcal{V}(K_X) \)). The support of \( A \) is given by the equation (3.1). For more details, see [Hi, BNR] and [Si].
The symplectic bundle structure \( \omega : E \otimes E \to L \) corresponds to an isomorphism

\[
\sigma^* A \xrightarrow{\cong} Ext^1(A, K_S \otimes p^* K_X) \otimes p^* L
\]

where \( \sigma : S \to S \) is the involution \( y \mapsto -y \) (note that the spectral curve is invariant under this involution because all the exponents of \( y \) in (3.1) are even integers). Indeed, applying \( p_* \) to this isomorphism we obtain the symplectic structure:

\[
p_* \sigma^* A = E \to p_* (Ext^1(A, K_S \otimes p^* K_X^{-1})) \otimes L = E^\vee \otimes L.
\]

The second equality is proved in two steps. There is a spectral sequence

\[
R^i p* Ext^j(\cdot, \cdot) \Rightarrow Ext^{i+j}(\cdot, \cdot).
\]

Since \( A \) has support of dimension 1, we obtain

\[
p_* (Ext^1(A, K_S \otimes p^* K_X^{-1})) = Ext^1_p(A, K_S \otimes p^* K_X^{-1}),
\]

and the relative Serre duality for the projective morphism \( p \) gives

\[
Ext^1_p(A, K_S \otimes p^* K_X^{-1}) = p_*(A)^\vee = E^\vee.
\]

We can think of \( A \) as a sheaf on the spectral curve \( X_s \). If this is integral, then \( A \) is torsionfree as a sheaf on \( X_s \), and then

\[
Ext^1(A, K_S \otimes p^* K_X) = A^\vee \otimes K_{X_s} \otimes \pi^* K_X^{-1},
\]

where \( \pi : X_s \to X \) is the projection. For an arbitrary coherent sheaf \( A \) on \( S \) supported on \( X_s \), define

\[
A^\vee := Ext^1(A, K_S) \otimes Ext^1(O_{X_s}, K_S)^\vee.
\]

If \( A \) is locally free on \( X_s \), then \( A^\vee \) is the usual dual line bundle on \( X_s \).

Fix once and for all a square root line bundle \( R = (K_{X_s} \otimes \pi^* K_X^{-1} \otimes \pi^* L)^{1/2} \). If we denote \( U = A \otimes R \), then \( \sigma^* U \cong U^\vee \). In other words, \( U \) is an element of the Prym subvariety of the compactified Jacobian \( \mathcal{J}(X_s) \)

\[
Prym(X_s, \sigma) = \{ U \in \mathcal{J}(X_s) : \sigma^* U \cong U^\vee \},
\]

and, conversely, an element of this Prym produces a symplectic Higgs bundle whose spectral curve is \( X_s \). Therefore, the fiber of \( H \) over \( s \in W \) is isomorphic to \( Prym(X_s, \sigma) \), and the isomorphism depends only on the choice of square root \( R \). The dimension of this Prym variety is

\[
g(X_s) - g(X_s/\sigma) = n(2n + 1)(g(X) - 1) = \dim \text{Sp}(2n)(g - 1).
\]

Let \( Y \) be an integral curve whose only singularity is one simple node at a point \( y \). Let

\[
\pi_Y : \tilde{Y} \to Y
\]

be the normalization, and let \( x \) and \( z \) be the pre-images of \( y \) in \( \tilde{Y} \). The compactified Jacobian \( \mathcal{J}(Y) \), which parametrizes torsionfree sheaves of rank 1 and degree 0 on \( Y \), is birational to a \( \mathbb{P}^1 \)-fibration \( P \) over \( J(\tilde{Y}) \), whose fiber over any \( L \in J(\tilde{Y}) \) is \( \mathbb{P}^1(L_x \oplus L_z) \). The morphism \( P \to \mathcal{J}(Y) \) is constructed as follows. A point of \( P \) corresponds to a line bundle \( L \) on \( \tilde{Y} \) and a one dimensional quotient \( q : L_x \oplus L_z \to \mathbb{C} \) (up to scalar multiple). This is sent to the torsionfree sheaf \( L' \) on \( Y \) defined as

\[
0 \to L' \to (\pi_Y)_* L \xrightarrow{q} C_y \to 0.
\]

For the proof, see [14, Theorem 4].

Assume that \( Y \) has an involution \( \sigma \). It lifts to an involution \( \tilde{\sigma} \) of \( \tilde{Y} \). This induces an involution in \( P \). Indeed, if \( (L, q) \) is a point, and \( q : L_x \oplus L_z \to \mathbb{C} \) is represented by
the divisor consisting of characteristic polynomials with singular spectral curves. This has two components
\[ \mathcal{D} = \mathcal{D}_1 \cup \mathcal{D}_2, \]
where \( \mathcal{D}_1 \) consists of those curves for which \( s_{2n} \) has a double root (then (3.1) has a node at the horizontal axis), and \( \mathcal{D}_2 \) consists of curves with two symmetrical nodes (i.e., \( y^n + s_2(x)y^{n-1} + \ldots + s_{2n-2}(x)y + s_{2n}(x) = 0 \) has a node). Let \( \mathcal{D}_i' \subset \mathcal{D}_i, i = 1, 2, \) be the locus of all those curves that do not contain extra singularities. Finally let \( \mathcal{D}^* = \mathcal{D} - (\mathcal{D}_1' \cup \mathcal{D}_2' ). \)

**Proposition 3.1.** As before, \( h : T^* M_{sp}(L) \rightarrow W \) is the Hitchin map. The following statements hold:

1. For \( w \in W - \mathcal{D}, \) the fiber \( h^{-1}(w) \) is an open subset of an abelian variety (actually a Prym variety).
2. For \( w \in \mathcal{D}_1', \) the fiber \( h^{-1}(w) \) is an open subset of the uniruled variety \( \text{Prym}(X_w, \sigma). \)
3. For \( w \in \mathcal{D}_2', \) the fiber \( h^{-1}(w) \) is an open subset of the uniruled variety \( \text{Prym}(X_w, \sigma). \)

The complement of the open subsets in each of the cases is of codimension at least 2 (at least for generic \( w \) in the corresponding set).
Proof. The map $H : \mathcal{M}_{\text{Sp}}(L) \rightarrow W$ is proper. By \cite{Hi}, $H^{-1}(w)$ is an abelian variety for $w \in W - D$. The complement

$$\mathcal{M}_{\text{Sp}}(L) - T^*\mathcal{M}_{\text{Sp}}(L)$$

is of codimension $\geq 3$ (the assumption that $g \geq 3$ is used here). In \cite{Fa} Theorem II.6 (iii) it is proved that the complement has codimension $\geq 2$ under a weaker assumption, but if we assume $g \geq 3$, then the same proof gives that the codimension is $\geq 3$.

Therefore, $(\mathcal{M}_{\text{Sp}}(L) - T^*\mathcal{M}_{\text{Sp}}(L)) \cap D_i$ is of codimension at least 2 in $D_i$, so for generic $w \in D_i^0$,

$$H^{-1}(w) - h^{-1}(w) \subset H^{-1}(w)$$

is of codimension at least 2.

The computations of $H^{-1}(w)$ for $w \in D_i^0$ were done in the arguments above.

Proposition 3.2. The hypersurfaces $h^{-1}(D^*)$ are irreducible.

Proof. We need to see that $h^{-1}(D^*)$ is of codimension at least two in $T^*\mathcal{M}_{\text{Sp}}(L)$. This follows easily from Theorem II.5 of \cite{Fa}, which says that the fibers of the Hitchin map $H : \mathcal{M}_{\text{Sp}}(L) \rightarrow W$ are Lagrangian (hence of half-dimension). So the fibers of $H$ are equidimensional, and in particular the codimension of $h^{-1}(D^*)$ is that of $D^* \subset W$, which is at least two.

The inverse image $h^{-1}(D)$ is called the Hitchin discriminant.

Theorem 3.3. The Hitchin discriminant $h^{-1}(D)$ is the closure of the union of the (complete) rational curves in $T^*\mathcal{M}_{\text{Sp}}(L)$.

Proof. Let $l \cong \mathbb{P}^1 \subset h^{-1}(D)$. Then $h(l) \subset W$. As it is a complete curve, it should be a point. So $l$ is included in a fiber. By Proposition 3.1 it cannot be contained in a fiber over $w \in W - D$.

Now let $w \in D^*$. Then Proposition 3.2 again shows that there is a family of $\mathbb{P}^1$ covering these fibers. Now using Proposition 3.2 we get that the closure is the entire $h^{-1}(D)$. \qed

4. Torelli theorem

This section is devoted to a Torelli type theorem for the moduli space $\mathcal{M}_{\text{Sp}}(L)$, i.e., to prove that the moduli space determines the curve $X$ up to isomorphism.

Lemma 4.1. The global algebraic functions $\Gamma(T^*\mathcal{M}_{\text{Sp}}(L))$ produce a map

$$\tilde{h} : T^*\mathcal{M}_{\text{Sp}}(L) \rightarrow \text{Spec}(\Gamma(T^*\mathcal{M}_{\text{Sp}}(L))) \cong W \cong \mathbb{C}^N,$$

which is the Hitchin map up to an automorphism of $\mathbb{C}^N$, where $N = \dim \mathcal{M}_{\text{Sp}}(L)$.

Moreover, consider the standard dilation action of $\mathbb{C}^*$ on the fibers of $T^*\mathcal{M}_{\text{Sp}}(L)$. Then there is a unique $\mathbb{C}^*$-action "\~" on $W$ such that $h \in \mathbb{C}^*$-equivariant, meaning $\tilde{h}(E, \lambda \theta) = \lambda \cdot \tilde{h}(E, \theta)$.

Proof. This holds for the Hitchin map $H$ on the moduli of semistable symplectic Higgs bundles $\mathcal{M}_{\text{Sp}}(L)$ (cf. \cite{Hi}). On the other hand, the generic fiber of $H$ is smooth and the codimension of $T^*\mathcal{M}_{\text{Sp}}(L) \subset \mathcal{M}_{\text{Sp}}(L)$ on these fibers is at least two (cf. \cite{Fa} Theorem II.6 (i)), and note that $T^*\mathcal{M}_{\text{Sp}}(L)$ is a subset of the moduli $\mathcal{M}_{\text{Sp}}^0(L)$ of stable Higgs bundles). Therefore, it follows that the lemma also holds for the restriction of the Hitchin map to the cotangent bundle $T^*\mathcal{M}_{\text{Sp}}(L)$. \qed
Lemma 4.1 allows us to recover the base $W$ of the Hitchin fibration as an algebraic manifold. Although there is an isomorphism $W \cong \bigoplus_{k=1}^{n} H^0(K_X^{2k})$, we do not know at this point how to recover the spaces $W_{2k} \subset W$ corresponding to $H^0(K_X^{2k})$. Lemma 4.1 also gives us the natural $\mathbb{C}^*$-action on $W$. This gives us the origin of $W$ (as the only fixed point of the action). Also the subspaces $W_{2k} = \bigoplus_{t=k}^{n} W_{2t}$, for each $t = 2, \ldots, n$, are uniquely determined (these are the spaces where the ratio of convergence is bigger than $\lambda^{2k}$, for $\lambda \to 0$). In particular, $W_{2n} \subset W$ is well-determined. Moreover, the $\mathbb{C}^*$-action on $W_{2n}$ determines the usual $\mathbb{C}^*$-action of weight one, which is multiplication by scalars. This determines the vector space structure of $W_{2n}$. So we recover $W_{2n} = H^0(K_X^{2n})$.

**Proposition 4.2.** Let $\mathcal{C}$ be the intersection of $W_{2n} = H^0(K_X^{2n}) \subset W$ with $D_1 \cup D_2$. This $\mathcal{C}$ is irreducible. Moreover $\mathbb{P}(\mathcal{C}) \subset \mathbb{P}(W_{2n})$ is the dual variety of $X \subset \mathbb{P}(W_{2n}^*)$ for the embedding given by the linear series $|K_X^{2n}|$.

**Proof.** A spectral curve corresponding to a point of $s_{2n} \in H^0(K_X^{2n})$ has equation $y^{2n} + s_{2n}(x) = 0$, and this curve is singular at the points with coordinates $(x, 0)$ such that $x$ is a zero of $s_{2n}$ of order at least two. Clearly $\mathcal{C} = D_1 \cap W_{2n}$. On the other hand, $D_2 \cap W_{2n} \subset \mathcal{C}$, since it consists of singular curves. Therefore, the first statement follows.

The elements $b \in W_{2n}$ correspond to spectral curves of the form $y^{2n} + b(x) = 0$. We have $b \in \mathcal{C}$ if and only if there is some $x_0$ such that $b(x_0) = 0$ and $b'(x_0) = 0$ simultaneously, therefore $b \in H^0(K_X^{2n}(-2x_0)) \subset H^0(K_X^{2n})$. From this the second statement follows, taking into account that the linear system $|K_X^{2n}|$ is very ample, so $X$ is embedded.\qed

Denote $\mathcal{C}_x = H^0(K_X^{2n}(-2x)) \subset W_{2n}$

Then $\mathcal{C} = \bigcup_{x \in X} \mathcal{C}_x$,

and taking the bundle of tangent hyperplanes to $X \subset \mathbb{P}(W_{2n}^*)$, we have

$$
\tilde{\mathcal{C}} = \bigcup \mathcal{C}_x \xrightarrow{F} \mathcal{C} \xrightarrow{} X
$$

We shall also need to consider the bundle of hyperplanes through a given point of $x$, i.e.,

$$
\tilde{\mathcal{H}} = \bigcup \mathcal{H}_x \longrightarrow X,
$$

where

$$
\mathcal{H}_x = H^0(K_X^{2n}(-x)) \subset W_{2n}.
$$

This is intrinsically defined once we have obtained $X$.

The following theorem is proved in [BH] by a different method.

**Theorem 4.3** (Torelli). Let $X$ and $X'$ be two smooth projective curves of genus $g \geq 3$, and let $M_{Sp}(L)$ and $M_{Sp}'(L')$ be moduli spaces of stable symplectic bundles over $X$ and $X'$ respectively. If the variety $M_{Sp}(L)$ is isomorphic to $M_{Sp}'(L')$, then $X \cong X'$. 

Remark 4.5. Let us see that we can extend the previous arguments to recover
Suppose $\Phi : \mathcal{M}_{Sp}(L) \rightarrow \mathcal{M}_{Sp}'(L')$ is an isomorphism. Then there is an
isomorphism $d\Phi : T^*\mathcal{M}_{Sp}(L) \rightarrow T^*\mathcal{M}_{Sp}'(L')$. By Lemma 4.1, there is a commutative diagram
\[
\begin{array}{ccc}
T^*\mathcal{M}_{Sp}(L) & \xrightarrow{d\Phi} & T^*\mathcal{M}_{Sp}'(L') \\
\downarrow & & \downarrow \\
W & \xrightarrow{f} & W'
\end{array}
\]
for some isomorphism $f : W \rightarrow W'$. The $C^*$-actions by dilations on the fibers
of $T^*\mathcal{M}_{Sp}(L)$ and $T^*\mathcal{M}_{Sp}'(L')$ induce $C^*$-actions on $W$ and $W'$, and $f$ should be $C^*$-equivariant (as $d\Phi$ is $C^*$-equivariant). Therefore $f : W_{2n} \rightarrow W'_{2n}$, and it is linear.

We have seen in Proposition 3.1 that the Hitchin discriminant $\mathcal{D} = \mathcal{D}_1 \cup \mathcal{D}_2 \subset W$ is an intrinsically defined subset, and therefore it is preserved by $f$. So $f$ preserves $\mathcal{C} = \mathcal{D} \cap W_{2n}$. This induces an isomorphism of the corresponding dual varieties, hence by Proposition 4.2 an isomorphism $\sigma : X \rightarrow X'$ is obtained. \[\square\]

**Remark 4.4.** Take $X$ and $X'$ as in Theorem 4.3. Let $\overline{\mathcal{M}}_{Sp}(L)$ and $\overline{\mathcal{M}}_{Sp}'(L')$ be
moduli spaces of semistable symplectic bundles over $X$ and $X'$ respectively. The
proof of Theorem 4.3 gives that $X$ is isomorphic to $X'$ if $\overline{\mathcal{M}}_{Sp}(L) \cong \overline{\mathcal{M}}_{Sp}'(L')$.

**Remark 4.5.** Let us see that we can extend the previous arguments to recover
the (linear) projection $\pi_{2n} : W \rightarrow W_{2n}$ (even though we do not know the linear
structure of $W$). This means that the map $f$ in the proof of Theorem 4.3 commutes
with $\pi_{2n}$.

First of all, the two irreducible components $\mathcal{D}_1$, $\mathcal{D}_2$ of $\mathcal{D}$ are well characterized.
Suppose this for a moment. The divisor $\mathcal{D}_1$ consists of $(s_2, \ldots, s_{2n})$ such that there
exists a point $x \in X$ with $s_{2n}(x) = s'_{2n}(x) = 0$. So, writing $W = \bigoplus_{k=1}^{n-1} W_{2k} \subset W$, we have
\[
\mathcal{D}_1 = \bigcup_{x \in X} (W' \times \mathcal{C}_x) \subset W.
\]
As such, there is a unique rational map $\mathcal{D}_1 \dashrightarrow X$ (up to automorphisms of the base) whose fibers are connected and rational (actually, isomorphic to open subsets of linear spaces). This determines each fiber $W' \times \mathcal{C}_x$, $x \in X$, and a fortiori, the intersection $W' \subset W$ of all of them. It is not difficult to see that the information of $W_{2n}$, $W'$ and the $C^*$-action together give the decomposition $W = W' \times W_{2n}$. The projection $\pi_{2n}$ follows.

It remains to identify the subvariety $\mathcal{D}_1$. Linearize the $C^*$-action at the origin
of $W$. According to the weights, the tangent space $T_0 W$ decomposes as $\bigoplus_{k=1}^{n-1} W_{2k}$
(here the decomposition is clearly well-defined), and also $W' = \bigoplus_{k=1}^{n-1} W_{2k} \subset T_0 W$.
The tangent cone to $\mathcal{D}_1$ is $\bigcup_{x \in X} (W' \times \mathcal{C}_x) \subset T_0 W$. This is not the tangent cone to
$\mathcal{D}_2$. So this property (for instance) can be used to characterize $\mathcal{D}_1$.

5. **Nilpotent cone and flag variety**

We need some results on linear algebra about the space of symplectic endomorphisms. Let $(V, \omega)$ be a symplectic vector space of dimension $2n$. In this section, we want to study the *symplectic nilpotent cone*
\[
\mathcal{N} = \{ A \in \text{End}_{Sp} V \mid A^{2n} = 0 \}.
\]

**Lemma 5.1.** The following statements hold:
Proof. Statement (1) is clear, since $N$ is defined by the equations $q_2(A) = \ldots = q_{2n}(A) = 0$, where $p_A(t) = t^{2n} + q_2(A)t^{2n-2} + \ldots + q_{2n}(A)$ is the characteristic polynomial of $A \in \text{End}_\mathbb{C} V$. As $\dim \text{End}_\mathbb{C} V = n(2n+1)$, and we have $n$ equations, it follows that $\dim N = 2n^2$.

To prove statement (2), note that if $\pm \lambda_1, \ldots, \pm \lambda_n$ are the eigenvalues of $A$, then $\text{tr}(A^r) = 0$ for $r$ odd, and $\text{tr}(A^r) = 2 \sum \lambda_i^r$ for $r$ even. Then the equations $\text{tr}(A^r) = 0$, $r = 2, 4, \ldots, 2n$, are equivalent to $\lambda_1 = \ldots = \lambda_n = 0$, i.e., $A^{2n} = 0$.

Now we will prove statement (3). Let $B \in \text{End}_\mathbb{C} V$. Considering $\frac{d}{d\epsilon}|_{\epsilon=0} \text{tr}((A + \epsilon B)^{2r}) = 0$, $r = 1, \ldots, n$, we see that

$$T_A N = \{ B \mid \text{tr}(A^{2r-1}B) = 0, r = 1, \ldots, n \}.$$ 

This has codimension strictly less than $n$ when $A^{2n-1} = 0$. So $\ker A = 2n - 1$ at a smooth point. For the converse, if $\ker A = 2n - 1$, then the matrices $I, A, A^2, \ldots, A^{2n-1}$ are linearly independent, and $A^{2k-1} \in \text{End}_\mathbb{C} V$, $k = 1, \ldots, n$. Therefore, the $n$ equations $\text{tr}(A^{2r-1}B) = 0$, $r = 1, \ldots, n$, for $B \in \text{End}_\mathbb{C} V$ are linearly independent, and $\dim T_A N = n$. Hence $A \in N^{sm}$, as required.

Finally we prove statement (4). Note that if $A \in N^{sm}$, then $\ker A = 2n - 1$. This determines a well-defined full flag

$$0 \subset \ker A \subset \ker A^2 \subset \ldots \subset \ker A^{2n-1} \subset \mathbb{C}^{2n}.$$ 

Let us see that $\ker A^i$ is dual (with respect $\omega$) to $\ker A^{2n-i}$. For this, note that $\ker A^{2n-i} = \text{im} A^i$. If $u = A^i u_0$, and $v \in \ker A^i$, then

$$\omega(u, v) = \omega(A^i u_0, v) = (-1)^i \omega(u_0, A^i v) = 0.$$ 

This means that the flag in (5.1) is isotropic (in particular, $\ker A^n$ is Lagrangian).

The fiber over a point of the flag variety is given as follows. Fix a symplectic basis $e_1, \ldots, e_n, e_{n+1}, \ldots, e_{2n}$, such that the flag is

$$\langle e_n \rangle \subset \langle e_{n-1}, e_n \rangle \subset \ldots \subset \langle e_1, \ldots, e_n \rangle \subset \langle e_1, \ldots, e_n, e_{n+1} \rangle \subset \cdots \subset \langle e_1, \ldots, e_{2n} \rangle.$$ 

Then the matrices in the fiber are of the form

$$\begin{pmatrix} A & B \\ 0 & -A^T \end{pmatrix},$$ 

where $A = \begin{pmatrix} 0 & 0 & 0 & \ldots & 0 \\ a_{21} & 0 & 0 & \ldots & 0 \\ a_{31} & a_{32} & 0 & \ldots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ a_{n,1} & a_{n,2} & \ldots & a_{n,n-1} & 0 \end{pmatrix}$

with $a_{i+1,i} \neq 0$, and $B = (b_{ij})$ is symmetric with $b_{11} \neq 0$. So the fiber of

$$\pi : N^{sm} \longrightarrow \text{Fl}(V, \omega)$$ 

is $(\mathbb{C}^*)^n \times \mathbb{C}^{n^2-n}$ (recall that $\text{Fl}(V, \omega)$ is defined in the statement (4) of the lemma). \qed
We will now prove that $N^{sm}$ determines $Fl(V, \omega)$. Consider the fibration $\pi$ in Lemma 5.1 (4). We shall show that the fibers of $\pi$ are intrinsically defined. Take any $F \in Fl(V, \omega)$. Let 

$$U_F \subset N \subset \text{End}_{Sp}(V)$$

be the space of symmetric endomorphisms respecting the flag $F$. It is a linear subspace of $\text{End}_{Sp}(V)$ of dimension $n^2$ contained in the nilpotent cone. By Lemma 5.2 below, all subspaces of $\text{End}_{Sp}(V)$ of dimension $n^2$ contained in the nilpotent cone are of the form $U_F$ for some $F$. Moreover, $U_F \cap N^{sm}$ is the fiber of $\pi$ over $F$. Therefore $\pi$ is uniquely defined, up to automorphism of the base.

**Lemma 5.2.** Let $L \subset N \subset \text{End}_{Sp}(V)$ be a linear subspace of dimension $n^2$ such that $L \cap N^{sm} \neq \emptyset$. Then there exists a unique flag $F$ such that $L = U_F$.

**Proof.** We shall divide the proof in several steps.

**Step 1.** $\text{tr}(A^iB) = 0$, for any $A, B \in L$, $i \geq 0$. If $i$ is even, then $A^iB$ is an anti-symmetric endomorphism, hence of zero trace. For $i$ odd, note that $\text{tr}(C^{2j}) = 0$ for any $C \in N$, $j \geq 0$. Then considering that $C_\lambda = A + \lambda B \in L \subset N$, we have that $\text{tr}(C^{i+1}_\lambda) = \text{tr}((A + \lambda B)^{i+1}) = 0$. Take the coefficient of $\lambda$ to get $\text{tr}(A^iB) = 0$.

**Step 2.** Let $A \in N$. Then $A \in L$ if and only if $\text{tr}(AB) = 0$, for all $B \in L$.

The “only if” part follows from Step 1.

To prove the “if” part, suppose that $\text{tr}(AB) = 0$, for all $B \in L$. As $A \in N$, we can choose a flag so that $A \in U$ (this is unique if $A \in N^{sm}$). Taking an appropriate symplectic basis, the flag is the one in (5.2), and there is a well-defined space $U$ of symplectic symmetric matrices (see (5.3)) preserving the flag.

Denote $U^T = \{B^T \mid B \in U\} \subset \text{End}_{Sp}(V)$. Consider also the space $D \subset \text{End}_{Sp}(V)$ consisting of symmetric symplectic diagonal matrices. Therefore

$$\text{End}_{Sp}(V) = U \oplus D \oplus U^T.$$ 

The bilinear map $q(B_1, B_2) = \text{tr}(B_1B_2)$ is symmetric and non-degenerate. The $q$-dual of $U$ is $U + D$. As $\text{End}_{Sp}(V)/(U + D) = U^T$, there is an induced perfect pairing $q : U \times U^T \rightarrow \mathbb{C}$. Let $p = p_{U^T} : \text{End}_{Sp}(V) \rightarrow U^T$ be the projection. Now $L \cap (U + D) = L \cap U$, since all elements of $L$ are nilpotent. Let us see that $L \cap U$ is $q$-dual to $p(L)$. Clearly, $q(B, C_1) = \text{tr}(BC_1) = \text{tr}(BC) = 0$, for $B \in L \cap U$, $C_1 \in p(L)$ and $C = C_1 + C_2 \in L$, with $C_2 \in U + D$. On the other hand,

$$\dim(L \cap U) + \dim p(L) = \dim L = \dim U.$$

Therefore, $p(L) \subset U^T$ and $L \cap U \subset U$ are $q$-orthogonal complements.

The conclusion is that given $B \in U$, we have $B \in L \cap U$ if and only if $q(B, C_1) = 0$ for all $C_1 \in p(L)$. In short, $B \in L \cap U$ if and only if $\text{tr}(BC) = 0$, for all $C \in L$.

**Step 3.** If $A \in L$ then $A^{2i-1} \in L$ for any $i \geq 1$. Without loss of generality, we can suppose $A \in N^{sm}$. Therefore, $A$ determines a flag $F$, and a space $U = U_F$ of endomorphisms preserving the flag. By Step 1, $\text{tr}(A^{2i-1}B) = 0$, for any $B \in L$. By Step 2, we have $A^{2i-1} \in L$.

**Step 4.** Let $A, B \in L$, then $A^2B + BA^2 + ABA \in L$. Let $C_\lambda = A + \lambda B \in L$. Then $C_\lambda^3 = (A + \lambda B)^3 \in L$ by Step 3. Take the coefficient of $\lambda$, to conclude the statement.

**Step 5.** Let $A \in L \cap N^{sm}$. Let $F$ be the (isotropic) flag determined by $A$, and let $U = U_F$. Denote as $0 \subset V_1 \subset V_2 \subset \cdots \subset V_{2n} = V$ the flag $F$. For $B \in L$, let
Let \( r(B) \in \mathbb{Z} \) be the minimum integer such that \( B(V_i) \subset V_{i-r} \). (Note that if \( r(B) < 0 \) is equivalent to \( B \in U \).) We claim that either \( r(B) < 0 \) or \( r(B) \) is odd.

Let \( r = r(B) \). If \( r = 0 \), then \( B \in U + D \). As \( B \) is nilpotent, it follows that \( B \in U \), meaning \( r < 0 \). Now we work by induction on \( r \). Suppose that \( r > 0 \) and it is even. Write \( B = (b_{ij}) \), in some basis adapted to the flag, and note that \( b_{ij} = 0 \) for \( i-j > r \). Let \( b_i = b_{r+i,i} \), \( i = 1, \ldots, 2n-r \). By Step 4, we have \( C = A^2B + BA^2 + ABA \in L \). It is easy to see that \( r(C) \leq r - 2 \), and that it has coefficients

\[
\begin{align*}
  c_1 &= b_1, c_2 = b_1 + b_2, c_3 = b_1 + b_2 + b_3, \ldots, c_i &= b_{i-2} + b_{i-1} + b_i, \\
  \ldots, c_{2n-r+1} &= b_{2n-r-1} + b_{2n-r}, c_{2n-r+2} = b_{2n-r}.
\end{align*}
\]

By induction hypothesis, \( r(C) \neq r - 2 \), so \( r(C) < r - 2 \) and all \( c_i = 0 \). From here, \( b_i = 0 \) for all \( i \), and so \( r(B) < r \).

**Step 6.** With the notation as in Step 5, \( r = r(B) > 1 \). Suppose that \( r = 1 \). Let \( \{v_i\} \) be a basis adapted to the flag, i.e. \( V_i = \langle v_1, \ldots, v_i \rangle \), for all \( i = 0, \ldots, 2n \), and consider the coefficients \( b_i := b_{1+i,i}, i = 1, \ldots, 2n-1 \), not all equal to zero.

Suppose first that all \( b_i \neq 0 \). Then \( B \) has rank \( 2n-1 \), so \( \ker B \) is 1-dimensional. Actually, if \( v \) spans \( \ker B \), then \( v \notin V_{2n-1} \). So choose the basis so that \( v_{2n} = v \) and \( v_k = A(v_{k+1}) \), \( k = 1, \ldots, 2n-1 \). Therefore \( A \) has standard Jordan form and \( b_{j,2n} = 0 \), \( j \). So \( \det(B + \lambda A) = b_{2n-1} \lambda \det(B' + \lambda A') \), where \( A', B' \) are \((2n-2) \times (2n-2)\)-matrices obtained from \( A, B \) by removing the last two columns and rows. By induction, this determinant is non-zero. Therefore \( A + \lambda B \) is not nilpotent for generic value of \( \lambda \). This is a contradiction, since \( A + \lambda B \in L \subset \mathcal{N} \).

Now suppose that \( b_{i_0} = 0 \), \( b_{i_0+2k} \neq 0 \), \( b_{i_0+1}, \ldots, b_{i_0+2k-1} \neq 0 \). Then take the blocks formed by rows and columns \( i_0 + 1, \ldots, i_0 + 2k \) which produce matrices \( A', B' \) of even size, such that \( A' + \lambda B' \) is nilpotent for all \( \lambda \). But \( \det(A' + \lambda B') \neq 0 \), which is proved as before.

The next case is that \( b_{i_0} = 0 \), \( b_{i_0+2k} = 0 \), but \( b_{i_0+1}, \ldots, b_{i_0+2k} \neq 0 \). Choose one such possibility with the smallest possible value of \( k \). Let \( W \subset \mathbb{C}^{2n-1} \) be the subspace parametrizing vectors \( (b_i) \) arising from matrices \( B \in L \) with \( r(B) = 1 \). And let \( W_{i_0,2k+1} \) be the subspace of those vectors \( (b_{i_0+1}, \ldots, b_{i_0+2k}) \) where \( (b_i) \in W \), \( b_{i_0} = 0 \), \( b_{i_0+2k+1} = 0 \). If this has dimension \( \geq 2 \), then there is a vector with some coordinate zero. Therefore, there is a smaller \( k \). So \( \dim W_{i_0,2k+1} = 1 \). Step 4 implies that if \( (b_{i_0+1}, \ldots, b_{i_0+2k}) \in W_{i_0,2k+1} \) then

\[
(b_{i_0+1} + b_{i_0+2}, b_{i_0+2} + b_{i_0+2}, b_{i_0+2} + b_{i_0+3}, \ldots, b_{i_0+2k-1} + b_{i_0+2k} + b_{i_0+2k+1} + b_{i_0+2k}) \in W_{i_0,2k+1}.
\]

As this vector is a multiple of the previous one, it must be

\[
(b_{i_0+1} + b_{i_0+2} = b_{i_0+3} + \ldots = b_{i_0+2k} + b_{i_0+2k}).
\]

This implies the vanishing of all \( b_i \) unless \( k = 1 \). And moreover, if \( k = 1 \), then taking the \( 3 \times 3 \)-matrix with rows and columns \( i_0 + 1, i_0 + 2, i_0 + 3 \), we get that \( b_{i_0+1} = \alpha, b_{i_0+2} = -\alpha \), for some \( \alpha \in \mathbb{C} \), by using that \( B' + \lambda A' \) should be nilpotent.

So the elements of \( W \) are of the form \( (\ldots, 0, \alpha_1, -\alpha_1, 0, \ldots, 0, \alpha_2, -\alpha_2, 0, \ldots) \).

Now consider the space \( H^T := \{B \in U^T \mid r(B) \leq 2\} \). The dual of \( H^T \) under \( q \) is denoted \( G \subset U \), and let \( H := U/Z \), with projection \( p_H : U \to H \). So there is a perfect pairing \( q : H^T \times H \to \mathbb{C} \). Recall that Step 2 says that \( U \cap L = q \)-dual to \( p_{U^T}(L) \). Therefore \( p_{U^T}(L) \cap H^T \) and \( p_{H}(U \cap L) \) are \( q \)-dual. Now consider \( B_2 \in p_{U^T}(L) \cap W^T \). Then \( B = B_1 + B_2 \in L \), where \( B_2 \in U + C \), and \( r(B) \leq 2 \).
Step 5. $r(B) \leq 1$. By the previous discussion, if $r(B) = 1$, then the entries $(b_i) \in W$ have the form given above.

So $p_H(U \cap L)$ contains matrices with any values in the second diagonal, and with values in the first diagonal of the form $(\ldots, \ast, \beta_1, \beta_1, \ast, \ldots, \beta_2, \ast, \ldots)$.

Now just consider a matrix $C \in U \cap L$ with all zeroes on the first diagonal, and just one 1 in the second diagonal, in a position $(i_0, i_0 + 2)$, so that the $3 \times 3$-block coming from $B + \lambda A + C \in L$ has a 1 in the right-top corner. This matrix is not nilpotent. This is a contradiction.

**Step 7.** $L = U$. Fix some $A \in L \cap N^{sm}$, and the corresponding subspace $U$. Let $B \in L$, and let $r = r(B)$. We only have to see that $r < 0$. If $r \geq 0$, then $r$ is odd from Step 5. By Step 6, it cannot be $r = 1$. The same argument as in Step 5, proves that it cannot be $r > 1$ and odd. So $B \in U$. Hence $L \subset U$, so they are equal by dimensionality. □

**Remark 5.3.** Lemma 5.2 also follows from the main theorem in [DKK]. The above proof, which uses only elementary methods, is included in order to be self-contained.

### 6. AUTOMORPHISMS OF THE MODULI SPACE

In this section we will compute the automorphism group of a moduli spaces of symplectic bundles on $X$. As before, we assume that $g \geq 3$.

**Proposition 6.1.** Fix a generic stable bundle $E \in M_{Sp}(L)$, and consider the map

$$h_{2n} : H^0(\End_{Sp} E \otimes K_X) \to W_{2n},$$

given as composition of the Hitchin map on $H^0(\End_{Sp} E \otimes K_X) = T_{Sp}(L) \subset T_{Sp}(L)$, followed by projection $\pi_{2n} : W \to W_{2n}$ (see Remark 4.7). Then

$$H^0(\End_{Sp} E \otimes K_X(-x_0)) = \{ \psi \in H^0(\End_{Sp} E \otimes K_X) \mid h_{2n}(\psi + \phi) \in \mathcal{H}_{x_0}, \forall \phi \in h^{-1}_{2n}(\mathcal{H}_{x_0}) \}$$

where $\mathcal{H}_x$ is defined in (4.1).

**Proof.** First, note that the sequence

$$0 \to H^0(\End_{Sp} E \otimes K_X(-x_0)) \to H^0(\End_{Sp} E \otimes K_X) \to \End_{Sp} E \otimes K_X|_{x_0} \to 0$$

is exact, since $H^1(\End_{Sp} E \otimes K_X(-x_0)) = H^0(\End_{Sp} E(x_0))^* = 0$, for a generic bundle, by Lemma 2.2. So the map

$$H^0(\End_{Sp} E \otimes K_X) \to \End_{Sp} E \otimes K_X|_{x_0},$$

given by $\phi \mapsto \phi(x_0)$, is surjective.

Note that $h_{2n}(\phi) = \det(\phi) \in W_{2n} = H^0(K_X^{2n})$. So

$$h_{2n}(\phi) \in \mathcal{H}_{x_0} \iff \det(\phi(x_0)) = 0.$$

The result follows from this easy linear algebra fact: if $(V, \omega)$ is a symplectic vector space, and $A \in \End_{Sp}(V)$ satisfies that $\det(A + C) = 0$ for any $C \in \End_{Sp}(V)$ with $\det(C) = 0$, then $A = 0$. □

Proposition 6.1 allows to construct the bundle

$$\mathcal{E} \to X$$

whose fiber over $x \in X$ is $\mathcal{E}_x = H^0(\End_{Sp} E \otimes K_X(-x))$. This is a subbundle of the trivial bundle

$$H^0(\End_{Sp} E \otimes K_X) \otimes O_X \to X,$$
Φ yields an isomorphism

\[ \sigma \]

**Proof.** Let \( M \) be the moduli space of symplectic bundles, and let \( E \in M_{Sp}(L) \) be a generic bundle, and let \( E' = \Phi(E) \). Then, by the previous argument, there is a bundle isomorphism \( \text{End}_{Sp}E \cong \text{End}_{Sp}E' \). From here we would like to deduce that \( E' \) is the twist of \( E \) by a line bundle. However, this is not known (at least, to the authors). This would amount to proving the generic injectivity of the map \( E \mapsto \text{End}_{Sp}E \) between the corresponding moduli spaces.

Because of this, we shall take an alternative route, determining first the nilpotent symplectic cones bundle, then the isotropic flag varieties bundle, and from this the Lie algebra structure of \( \text{End}_{Sp}E \). This actually determines \( E \) up to twist by a line bundle.

We start with the following lemma:

**Lemma 6.3.** The linear structure of the base of the Hitchin map \( W \) is uniquely determined. So is the decomposition \( W = \bigoplus_{k=1}^{n} W_{2k} \), where \( W_{2k} = H^{0}(K_{X}^{2k}) \), \( k = 1, \ldots, n \).

**Proof.** Let \( M_{Sp}(L) \) be the moduli space of symplectic bundles, and let \( \Phi : M_{Sp}(L) \rightarrow M_{Sp}(L) \) be an automorphism. As in the proof of Theorem 1.3, the automorphism \( \Phi \) yields an isomorphism \( \sigma : X \rightarrow X \) and commutative diagrams

\[ \begin{array}{ccc}
\tilde{C} & \rightarrow & \tilde{C} \\
\downarrow & & \downarrow \\
X & \stackrel{\sigma}{\rightarrow} & X
\end{array} \quad \text{and} \quad
\begin{array}{ccc}
\tilde{H} & \rightarrow & \tilde{H} \\
\downarrow & & \downarrow \\
X & \stackrel{\sigma}{\rightarrow} & X
\end{array} \]

(6.2)

Let \( M \) be a line bundle such that \( M_{\otimes 2} \cong L \otimes (\sigma^{*}L)^{\vee} \). Composing with the automorphism given by \( \sigma^{-1} \) and \( M^{-1} \) (see the introduction), we may assume that \( \sigma = \text{Id} \).

Take a generic bundle \( E \), and let \( E' \) be its image by \( \Phi \). Then we have

\[ T_{E}^{*}M_{Sp}(L) \overset{\Phi}{\rightarrow} T_{E'}^{*}M_{Sp}(L) \]

(6.3)

where \( f \) is an automorphism which commutes with the \( \mathbb{C}^{*} \)-action. To prove the lemma, we have to check that \( f \) is linear with respect to a chosen decomposition \( W = \bigoplus_{k=1}^{n} W_{2k} \).

There is a bundle \( \mathcal{E} \rightarrow X \) whose fiber over any \( x \in X \) is the subspace

\[ H^{0}(\text{End}_{Sp}E \otimes K_{X}(-x)) \subset T_{E}^{*}M_{Sp}(L) \].

Analogously, there is a bundle \( \mathcal{E}' \rightarrow X \) whose fiber over \( x \) is the subspace

\[ H^{0}(\text{End}_{Sp}E' \otimes K_{X}(-x)) \subset T_{E'}^{*}M_{Sp}(L) \].

By Proposition 6.1, the map \( d\Phi : T_{E}^{*}M_{Sp}(L) \rightarrow T_{E'}^{*}M_{Sp}(L) \) gives an isomorphism \( \mathcal{E} \rightarrow \mathcal{E}' \). Going to the quotient bundle (6.1), we have a bundle isomorphism

\[ \text{End}_{Sp}E \otimes K_{X} \rightarrow \text{End}_{Sp}E' \otimes K_{X} \].
Let \( \varphi : \text{End}_\text{Sp} E \rightarrow \text{End}_\text{Sp} E' \) be the corresponding isomorphism. Then the map 
\[
d\Phi : H^0(\text{End}_\text{Sp} E \otimes K_X) \rightarrow H^0(\text{End}_\text{Sp} E' \otimes K_X)
\]
is induced by \( \varphi \).

The Hitchin map \( h : H^0(\text{End}_\text{Sp} E \otimes K_X) \rightarrow W \) factors as the composition of the map 
\[
H^0(\text{End}_\text{Sp} E \otimes K_X) \rightarrow \prod_{k=1}^n H^0(\bigwedge^2 \text{End}_\text{Sp} E \otimes K_X^{2k})
\]
and the trace map 
\[
\prod_{k=1}^n H^0(\bigwedge^2 \text{End}_\text{Sp} E \otimes K_X^{2k}) \rightarrow \prod_{k=1}^n W_{2k}.
\]

By the discussion above, the map \( d\Phi \) descends to a map 
\[
\prod_{k=1}^n H^0(\bigwedge^2 \text{End}_\text{Sp} E \otimes K_X^{2k}) \rightarrow \prod_{k=1}^n H^0(\bigwedge^2 \text{End}_\text{Sp} E' \otimes K_X^{2k})
\]
and is diagonal with respect to the product decomposition. Therefore, the map \( f : \prod_{k=1}^n W_{2k} \rightarrow \prod_{k=1}^n W_{2k} \) is also diagonal. Finally, this means that we have maps \( f : W_{2k} \rightarrow W_{2k} \) which are \( \mathbb{C}^* \)-equivariant. As there is just one weight for \( W_{2k} \), this means that \( f \) is linear on \( W_{2k} \). Therefore \( f \) is linear.

Our next step is to recover the symplectic nilpotent cone bundle 
\[ \mathcal{N}_E \rightarrow X, \]
whose fibers are the symplectic nilpotent cone spaces 
\[ \mathcal{N}_{E,x} = \{ A \in \text{End}_\text{Sp} E \otimes K_X | x \mid A^{2n} = 0 \} \subset \text{End}_\text{Sp} E \otimes K_X | x, \ x \in X. \]

Note that this nilpotent cone bundle sits as \( \mathcal{N}_E \subset \text{End}_\text{Sp} E \otimes K_X. \)

**Lemma 6.4.** Consider the map 
\[ h_{2k} : H^0(\text{End}_\text{Sp} E \otimes K_X) \rightarrow W_{2k}, \]
given as composition of the Hitchin map on 
\[ H^0(\text{End}_\text{Sp} E \otimes K_X) = T^*_E M_\text{Sp}(L) \subset T^* M_\text{Sp}(L), \]
followed by the projection \( W \rightarrow W_{2k} \) (defined thanks to Lemma 6.3). Then the vector subspace generated by the image \( h_{2k}(H^0(\text{End}_\text{Sp} E \otimes K_X(-x))) \) is 
\[ H^0(K_X^{2k}(-2k x)) \subset W_{2k} = H^0(K_X^{2k}). \]

**Proof.** The map \( h_{2k} \) sends \((E, \phi) \mapsto \text{tr}(\wedge^2 \phi)\). Therefore, 
\[ h_{2k}(H^0(\text{End}_\text{Sp} E \otimes K_X(-x))) \subset H^0(K_X^{2k}(-2k x)). \]

Now the vector space generated by \( h_{2k}(H^0(\text{End}_\text{Sp} E \otimes K_X(-x))) \) equals to the image of 
\[ \wedge^2 k : H^0(\text{End}_\text{Sp} E \otimes K_X(-x)) \otimes 2k \rightarrow H^0(\text{End}_\text{ant} E \otimes K_X^{2k}(-2k x)), \]
followed by the trace map \( H^0(\text{End}_\text{ant} E \otimes K_X^{2k}(-2k x)) \rightarrow H^0(K_X^{2k}(-2k x)), \) where \( \text{End}_\text{ant} E \) consists of the anti-symmetric symplectic endomorphisms of \( E \) (i.e., those \( \varphi \) such that \( \omega(\varphi u, v) = \omega(u, \varphi v) \)). Note that the multiples of the identity are in \( \text{End}_\text{ant} E. \)
There is a bundle map
\[(\operatorname{End}_{\mathcal{Sp}} E)^{\otimes 2k} \rightarrow \operatorname{End}_{\text{ant}} E \rightarrow \mathcal{O}_X\]
(first map is composition of endomorphisms, second map is the trace). This is split, therefore the map
\[H^0((\operatorname{End}_{\mathcal{Sp}} E)^{\otimes 2k} \otimes K^2_X(-2k x)) \rightarrow H^0(K^2_X(-2k x))\]
is surjective, as required.

Consider the vector subspace generated by the image \(h_{2k}(H^0(\operatorname{End}_{\mathcal{Sp}} E \otimes K_X(-x)))\) which is \(H^0(K^2_X(-2k x)) \subset W_{2k} = H^0(K^2_X),\) for moving the point \(x \in X.\) This gives a fiber bundle over \(X,\) which has co-rank \(2k.\) The curve \(X\) is embedded into \(\mathbb{P}(W^*_{2k})\) via the linear system \(|K^2_X|,\) and the osculating \(2k\)-space at \(x\) is given as
\[\operatorname{Osc}_{2k}(x) = \mathbb{P}(V_x) \subset \mathbb{P}(W^*_{2k}), \quad V_x := \ker(H^0(K^2_X)^* \rightarrow H^0(K^2_X(-2k x)^*).\]
The embedding of the curve \(X\) in \(\mathbb{P}(W^*_{2k})\) is recovered from the osculating \(2k\)-spaces. More specifically, if \(g : X \rightarrow \mathbb{P}^N\) and \(\tilde{g} : X \rightarrow \text{Gr}(2k+1, N+1)\) is the map giving the osculating \(2k\)-spaces, then \(\tilde{g}\) determines \(g.\) This is proved as follows: the pull-back of the universal bundle through \(\tilde{g}\) is the bundle
\[\mathbb{P}(\mathcal{O}_X \oplus TX \oplus (TX)^{\otimes 2} \oplus \ldots \oplus (TX)^{\otimes 2k}) \rightarrow X,\]
and \(g\) is determined by a section of this bundle. As \(TX\) is of negative degree, this has only one section.

So we recover the embeddings \(X \hookrightarrow \mathbb{P}(W^*_{2k}) = \mathbb{P}(H^0(K^2_X)^*),\) and hence the hyperplanes
\[H^{(2k)}_x := H^0(K^2_X(-x)) \subset W_{2k}.\]

Finally, consider
\[
\{ \phi \in H^0(\operatorname{End}_{\mathcal{Sp}} E \otimes K_X) \mid h_{2k}(\phi) \in H^{(2k)}_x, \forall k = 1, \ldots, n \}.
\]
This is the pre-image of the nilpotent cone under the surjective map
\[H^0(\operatorname{End}_{\mathcal{Sp}} E \otimes K_X) \rightarrow \operatorname{End}_{\mathcal{Sp}} E \otimes K_X|_x.\]
Take its image to get the bundle
\[N_E \rightarrow X.\]

Now we are ready to prove the main result of the paper. First, as explained in the introduction, line bundles of order two and automorphisms of \(X\) produce automorphisms of moduli spaces of symplectic bundles.

**Theorem 6.5.** Let \(M_{\mathcal{Sp}}(L)\) be the moduli space of symplectic bundles. Let
\[\Phi : M_{\mathcal{Sp}}(L) \rightarrow M_{\mathcal{Sp}}(L)\]
be an automorphism. Then \(\Phi\) is induced by an automorphism of \(X\) and a line bundle of order two.

**Proof.** We work as in Lemma 6.3. There is an automorphism \(\sigma : X \rightarrow X\) and a line bundle \(M,\) with \(M^\otimes 2 \cong L \otimes (\sigma^* L)^\vee\), such that, after composing with \(\sigma^{-1}\) and \(M^{-1}\) (as in the introduction), we have the diagram \(6.2\) with \(\sigma = \text{Id}\).

Take a generic bundle \(E,\) and let \(E'\) be its image by \(\Phi.\) By the arguments in Lemma 6.3 we have a bundle isomorphism
\[\varphi : \operatorname{End}_{\mathcal{Sp}} E \rightarrow \operatorname{End}_{\mathcal{Sp}} E',\]
and the diagram \((6.3)\) becomes
\[
\begin{array}{ccc}
H^0(\text{End}_{\sp2}\E \otimes K_X) & \xrightarrow{d\Phi} & H^0(\text{End}_{\sp2}\E' \otimes K_X) \\
h \downarrow & & h \downarrow \\
W & \xrightarrow{f} & W
\end{array}
\]
where \(h\) is the Hitchin map and \(f\) is a linear isomorphism. By Lemma \(6.4\) and the discussion following it, \(f\) preserves \(H^0(\sp2 K_x) \subset W,\) for each \(k = 1, \ldots, n,\) and \(x \in X.\)

Therefore \(d\Phi\) preserves \(\bigcap_{k \geq 1} h_{2k}^{-1}(H^0(\sp2 K_x)) \subset H^0(\text{End}_{\sp2}\E \otimes K_X).\) Taking the image under the surjective map \(H^0(\text{End}_{\sp2}\E \otimes K_X) \twoheadrightarrow \text{End}_{\sp2}\E \otimes K_X|_x,\) we see that \(d\Phi\) preserves the symplectic nilpotent cone \(N_{E,x},\) for all \(x \in X.\) So we have an isomorphism
\[
N_E \rightarrow N_{E'}
\]
where \(N_E, N_{E'}\) are the corresponding symplectic nilpotent cone bundles.

By Lemma \(5.2\) we get an isomorphism
\[
\text{Fl}(E, \omega) \rightarrow \text{Fl}(E', \omega')
\]
of the corresponding isotropic flag varieties bundles. Going to global vertical fields, we have a (Lie algebra) bundle isomorphism
\[
\text{ad}_{\sp2}\E \rightarrow \text{ad}_{\sp2}\E'
\]
Using Lemma \(6.6\) below, it follows that \(E' \cong E \otimes M,\) for some line bundle \(M\) with \(M^2 \cong O_X.\)

As this holds for a generic \(E,\) it holds for all \(E.\)

\textbf{Lemma 6.6.} Let \((E, E \otimes E \rightarrow L)\) and \((E', E' \otimes E' \rightarrow L')\) be two symplectic vector bundles such that \(\text{ad}_{\sp2}\E\) and \(\text{ad}_{\sp2}\E'\) are isomorphic as Lie algebra bundles. Then there is a line bundle \(M\) such that \(E' \cong E \otimes M.\)

Furthermore, if we assume \(L \cong L',\) then \(M^\otimes 2 \cong O_X.\)

\textbf{Proof.} Giving a vector bundle \(\text{ad}_{\sp2}\E\) with its Lie algebra structure is equivalent to giving a principal \(\text{Aut}(\sp2n)-\text{bundle}\) \(P_{\text{Aut}(\sp2n)}\) which admits a reduction to a principal \(\Gp_{2n}\)-bundle \(P_{\Gp_{2n}},\) corresponding to \((E, E \otimes E \rightarrow L).\)

Since \(\sp2n\) does not have outer automorphisms, all automorphisms are inner, and \(\text{Aut}(\sp2n)\) is connected. Therefore, we have
\[
\Gp_{2n} \rightarrow P\Gp_{2n} = \text{Inn}(\sl_{2n}) = \text{Aut}(\sl_{2n})
\]
Consider the short exact sequence of groups
\[
e \rightarrow \mathbb{C}^* \rightarrow \Gp_{2n} \rightarrow P\Gp_{2n} \rightarrow e
\]
Hence, the set of reductions of a \( \text{PG}p_{2n} \)-bundle to \( \text{G}p_{2n} \) is a torsor for the group \( H^1(X, \mathcal{O}_X^*) \). Therefore, if \( (E, E \otimes E \to L) \) is a symplectic bundle corresponding to a reduction, the other reductions are of the form
\[
(E \otimes M, (E \otimes M) \otimes (E \otimes M) \to L \otimes M^\otimes 2)
\]
for any line bundle \( M \).

Finally, it follows from this expression that, if \( L \cong L' \), then \( M^\otimes 2 \cong \mathcal{O}_X \). \( \Box \)

Let \( \text{Aut}(X) \) and \( \text{Aut}(\text{M}_{\text{Sp}}(L)) \) be the automorphisms of \( X \) and \( \text{M}_{\text{Sp}}(L) \) respectively. Let \( J(X)_2 \) be the group of line bundles on \( X \) of order two.

**Proposition 6.7.** There is a natural short exact sequence of groups
\[
e \to J(X)_2 \to \text{Aut}(\text{M}_{\text{Sp}}(L)) \to \text{Aut}(X) \to e.
\]

**Proof.** From the proof of Theorem 6.5, if follows that we have a surjective homomorphism
\[
\rho : \text{Aut}(\text{M}_{\text{Sp}}(L)) \to \text{Aut}(X).
\]
The homomorphism sends \( \Phi \) to \( \sigma \) (see the proof of Theorem 6.5). The kernel of \( \rho \) is a quotient of \( J(X)_2 \). Therefore, to prove the proposition it suffices to show that the action of \( J(X)_2 \) on \( \text{M}_{\text{Sp}}(L) \) is effective.

Let \( \text{M}_{\text{Sp}}(2, L) \) (respectively, \( \text{M}_{\text{Sp}}(2n - 2, L) \)) be the moduli space of symplectic bundles of rank 2 (respectively, \( 2n - 2 \)) such that the symplectic form takes values in \( L \). There is a natural embedding
\[
\text{M}_{\text{Sp}}(2, L) \times \text{M}_{\text{Sp}}(2n - 2, L) \to \overline{\text{M}}_{\text{Sp}}(L)
\]
(where \( \overline{\text{M}}_{\text{Sp}}(L) \) is the moduli space of semistable symplectic bundles), defined by \(((E_1, \varphi_1), (E_2, \varphi_2)) \mapsto (E_1 \oplus E_2, \varphi_1 \oplus \varphi_2)\). To prove that the action of \( J(X)_2 \) on \( \text{M}_{\text{Sp}}(L) \) is effective it is enough to show that the action of \( J(X)_2 \) on \( \text{M}_{\text{Sp}}(2, L) \) is effective.

First assume that \( \deg L = 2 \delta \), where \( \delta \) is an integer. Then for a general line bundle \( M \in J^\delta(X) \), the symplectic bundle \( M \oplus (L \otimes M^*) \in \text{M}_{\text{Sp}}(2, L) \) is moved by the action of every nontrivial element of \( J(X)_2 \). Therefore, the action of \( J(X)_2 \) on \( \text{M}_{\text{Sp}}(2, L) \) is effective.

Now assume that \( \deg L = 2 \delta + 1 \). Fix a nontrivial line bundle \( \xi \in J(X)_2 \). Take a pair \((E, \theta)\), where \( E \) is a stable vector bundle of rank two with \( \wedge^2 E = L \), and
\[
\theta : E \to E \otimes \xi
\]
is an isomorphism. Therefore, \( E \) is a fixed point for the action of \( \xi \) on \( \text{M}_{\text{Sp}}(2, L) \).

The line bundle \( \xi \) defines a nontrivial étale covering
\[
f : Y \to X
\]
of degree two, and \( E \) produces a line bundle \( \eta \to Y \) such that \( f_*\eta = E \) (see [BNR], [II]). Therefore, \( \eta \) lies in the Prym subvariety of \( J^{2\delta+1}(Y) \) associated to the covering \( f \). The dimension of the Prym variety is \( g - 1 \). On the other hand, the dimension of \( \text{M}_{\text{Sp}}(2, L) \) is \( 3g - 3 \). Since \( 3g - 3 > g - 1 \), we conclude that the action of \( \xi \) on \( \text{M}_{\text{Sp}}(2, L) \) is effective. This completes the proof of the proposition. \( \Box \)

**Lemma 6.8.** Let \( \overline{\text{M}}_{\text{Sp}}(L) \) be the moduli space of semistable symplectic bundles. The automorphism group of \( \overline{\text{M}}_{\text{Sp}}(L) \) is identified with \( \text{Aut}(\text{M}_{\text{Sp}}(L)) \).
Proof. The automorphisms of $M_{Sp}(L)$ given by $J(X)_2$ clearly extend to automorphisms of $\overline{M}_{Sp}(L)$. More generally, for any automorphism $\sigma : X \rightarrow X$, and any line bundle $M$ such that $M^\otimes 2 \cong L \otimes (\sigma^* L)^\vee$, the automorphism of $M_{Sp}(L)$ defined by

$$(E, \varphi) \mapsto (M \otimes \sigma^* E, \beta \otimes \sigma^* \varphi),$$

where $\beta$ is an isomorphism of $M^\otimes 2$ with $O_X$, extends to an automorphism of $\overline{M}_{Sp}(L)$.

On the other hand, from the proof of Theorem 6.5 it follows that any automorphism of the smooth locus of $M_{Sp}(L)$ extends to an automorphism of $\overline{M}_{Sp}(L)$. But the smooth locus of $M_{Sp}(L)$ coincides with the smooth locus of $\overline{M}_{Sp}(L)$. Any automorphism of a variety preserves the smooth locus. Therefore, $\text{Aut}(\overline{M}_{Sp}(L))$ is identified with $\text{Aut}(M_{Sp}(L))$. \(\blacksquare\)
