(Dated: May 27, 2020)

Efimov states are known to have a discrete real space scale invariance, working in momentum space we identify the relevant discrete scale invariance for the scattering amplitude defining its Weierstrass function as well. Through the use of the mathematical formalism for discrete scale invariance for the scattering amplitude we identify the scaling parameters from the pole structure of the corresponding zeta function, it’s zeroth order pole is fixed by the Efimov physics. The corresponding geometrical fractal structure for Efimov physics in momentum space is identified as a ray across a logarithmic spiral. This geometrical structure also appears in the physics of atomic collapse in the relativistic regime connecting it to Efimov physics. Transforming to logarithmic variables in momentum space we map the three-body scattering amplitude into Bloch states and the ladder of energies of the Efimov states are simply obtained in terms of the Bohr-Sommerfeld quantization rule. Thus through the mapping the complex problem of three-body short range interaction is transformed to that of a non-interacting single particle in a discrete lattice.

PACS numbers:

I. INTRODUCTION

The quantum physics of three body resonantly interacting particles is known to generate a universal hierarchy of shallow three body-states states as originally established by Efimov [1,2] for identical bosons. For a fairly recent review of the more general problem, e.g. treating the three fermion state, the effect of dimensionality as well as an update on the experimental side see [3]. For particles interacting through short-range attractive interactions that are nearly resonant the number of bound three particle states, Efimov states, becomes infinite if at least two of the two-body interactions have an infinite s-wave scattering length. Aside from the amazing fact that these states are formed in a regime where two particles can not bound, exhibiting what is referred to as Borromean binding, these three-particle bound states exhibit a discrete scaling symmetry. The discrete symmetry is manifested in the size $R_n$ and binding energy $E_n$ of the $n$–th Efimov state which scales spatially as $R_n = \lambda R_{n-1}$ and correspondingly for the energy as $E_n = \lambda^{-2} E_{n-1}$ with respect to the underlying $(n - 1)$ Efimov state. For the homonuclear Efimov states the scale factor is given by $\lambda_0 = e^{\pi/s_0}$ were $s_0 = 1.00624$ is a universal constant.

Having eluded experimental verification for over three decades since their initial prediction, Efimov states were experimentally observed [4] and their universality has been demonstrated (see Ref. [5] for an experimental review). The experimental observation was facilitated by the ability to greatly enhance the scattering length in atomic systems via Feshbach resonances attaining low-energy universality in atomic few-body systems which has lead to a surge of theoretical and experimental effort in the study of few body physics. Despite the large flow of experimental papers in which evidence for Efimov states was presented for homonuclear systems the experimental confirmation of the discrete scaling trait was long forthcoming. In 2014 two Efimov states of Cs atoms were subsequently observed [6] and three Efimov states were experimentally detected concurrently in a heteronuclear Li-Cs mixtures at the University of Chicago [7] and in Heidelberg [8].

Originally of interest to the cold atom and nuclear physics communities the importance of Efimov physics has been extended to many other fields. Only lately aspects of Efimov physics have been shown to be of relevance in solid state systems particularly to topological semi-metals and graphene. More specifically it is has been shown to be related to quasi-Rydberg resonances in graphene and to physics of atomic collapse [9] as well as to interaction of electron with an impurity in a Dirac semi-metal [10]. Recently the self similarity of Efimov states had been shown to extend to the time domain and ideas for observing the phenomena in cold atom systems [11] and trapped ion systems have been suggested [12]. Amazingly also a connection between Efimov physics and the the binding of three stranded DNA, which is a classical system, was established [13], exhibiting in a sense what has been referred to as biological Efmov effect.

On the theoretical side, Efimov first obtained his original solution employing hyper-spherical coordinates [1,2]. Though originally met with skepticism the validity of Efimov’s result was established both analytically and numerically by Amado and Noble [14,15]. Later the three body system with short range interactions was addressed in terms of an effective field theory (EFT) formulation of the problem [16-19]. Extensions of the theory beyond the three body system case have also been considered [20,21]. The scaling behavior of the Efimov states is most evident when transforming the problem to an effective
Schrödinger equation for a single particle in an inverse square potential \[19\]. The obtained Schrödinger equation is invariant under a continuous scale transformation; however, the problem is ill defined at short scales since the Hamiltonian is not self adjoint. To remedy this issue one needs to impose a boundary condition, resulting in a remarkable result: the boundary condition breaks the continuous scale invariance spontaneously into a discrete scale symmetry. Such a breaking of a continuous scale symmetry in the quantum domain is a manifestation of non-relativistic scale anomaly \[22\]. Another notable issue is that the scaling factor is universal in the sense that it is independent of the chosen boundary conditions in terms of renormalization group (RG), this effect is tied to the limit cycle behavior of the renormalization group flow equation \[23\]. It was originally proposed by Wilson \[24\] that the renormalization group equations can in addition to fixed point solutions also admit limit cycle solutions corresponding to a discrete scale invariance with respect to a scaling factor corresponding to the oscillation period. Such solutions exhibit a log-periodic dependence as a function of the characteristic scale. However limit cycle RG solutions are quite rare and Efimov physics is probably the most notable example of such a solution \[19, 23\].

Originally considered as an oddity in the energy spectrum of three particles with short-range interactions Efimov physics has long been established to have profound connections to a wide range of physical problems. On the theoretical side the Efimov spectrum has been shown to form a geometric series corresponding to an infinite number of weakly bound states with an accumulation at the zero energy threshold. The associated Efimov states thus posses a discrete scale invariance which is connected to a limit cycle RG limit. In this paper we focus on the geometrical aspect of Efimov states by employing the mathematical formalism for functions with discrete scale invariance (DSI), we identify the relevant scaling parameters and establish the appropriate Weierstrass function. The geometrical underlying fractal structure is identified and finally we use these observations to greatly simplify the problem by mapping it to that of a Bloch state.

The reminder of this paper is organized as follows. In Sec. \[II\] we give a brief introduction to Efimov physics, employing the EFT formulation. Specifically the scattering amplitude is calculated via EFT. The mathematics of functions possessing a DSI is shortly reviewed in Sec.\[III\]. The connection between scattering amplitude and DSI is established in Sec.\[IV\]. The geometrical aspect of Efimov states is identified as well. In this section the underlying fractal structure of the scattering amplitude is established to be a ray across a spiral. Transforming to logarithmic variables Efimov states are mapped to Bloch states in Sec.\[V\] and the Efimov spectrum is obtained from the Bohr-Sommerfeld quantization rule. A brief discussion of the real space formalism is presented in Sec.\[VI\]. Results are discussed and summarized in Sec.\[VII\].

**II. EFIMOV PHYSICS IN TERMS OF EFT IN A NUTSHELL**

It is convenient to introduce Efimov physics in terms of EFT, in this section we do so briefly for the sake of clarity. The presentation closely follows the method described in Refs. \[17, 19\]. The basis for the EFT is the most general non-relativistic Lagrangian for a boson field $\psi$ with mass $M$, which is invariant under small-velocity Lorentz transformation and parity,

$$\mathcal{L} = \psi^\dagger \left(i\partial_0 + \frac{\nabla^2}{2M}\right) \psi - \frac{C_0}{2}(\psi^\dagger \psi)^2 - \frac{D_0}{6}(\psi^\dagger \psi)^3 + \cdots,$$

where $C_0$ and $D_0$ are the bare low-energy coupling constants (LECs) for the two and three body interactions respectively. To make the theory renormalizable it is defined up to an ultraviolet cut-off, $\Lambda$. Introducing a dummy field, $d$, corresponding to a local operator which annihilates two Bosons at a point, the Lagrangian can be re-written without the three and the two body contact interaction terms,

$$\mathcal{L} = \psi^\dagger \left(i\partial_0 + \frac{\nabla^2}{2M}\right) \psi + \Delta(d^\dagger d) - \frac{g}{\sqrt{2}}(d^\dagger \psi \psi + h.c.) + h(d^\dagger d^\dagger \psi + h.c.)$$

Employing perturbation theory through a diagrammatic expansion in terms of Feynman diagrams, the first step involves calculating the dressed propagator for the dummy field, obtained by summing bubble diagrams to all orders. The next step is obtaining an integral for the Fourier transform of the amputated connected part of the Greens function $\langle 0 | T(d\psi d^\dagger \psi^\dagger) | 0 \rangle$, resulting in a Skorniakov-Ter-Martirosian (STM) equation \[25\] for the scattering amplitude

$$a_{sc}(p) = K(p,k) + \frac{2\lambda}{\pi} \int_0^\Lambda dq K(p,q) \frac{q^2}{q^2 - k^2 - i\epsilon} a_{sc}(q),$$

where $k(p)$ is the incoming (outgoing) momentum and $\lambda = 1$ for the bosonic case. For the case when $a_2$, the two particle $s$-wave scattering length, satisfies the following condition, $1/a_2 \ll p \ll \Lambda$ and $k \sim 1/a_2$, the Kernel in the integral Eq. \[3\] is approximated by

$$K(p,q) = \frac{2}{\sqrt{3}q} \ln \left(\frac{q^2 + pq + p^2}{q^2 - pq + p^2}\right).$$
The main contribution to the integral comes from momenta in the intermediate region $1/a_2 \ll q \ll \Lambda$ for which the following simplified integral equation can be obtained

$$a_{sc}(p) = \frac{4}{\sqrt{3\pi}} \int_0^\infty \frac{dq}{q} a_{sc}(q) h(q,p)$$  \hspace{1cm} (5)

where

$$h(q,p) = \ln \left( \frac{q^2 + pq + p^2}{q^2 - pq + p^2} \right).$$  \hspace{1cm} (6)

The scale invariance of the above Eq. (6) suggest a power-law solution $a_{sc}(p) \sim p^s$ to Eq. (5). Such a power-law solution requires that $s$ satisfy the following condition

$$1 - \frac{4}{\sqrt{3\pi}} \mathcal{M}_{h(q,p)}(s) = 0.$$  \hspace{1cm} (7)

where $\mathcal{M}_{h(q,p)}$ is the Mellin transform with respect to the variable, $q$ and the transform is defined as

$$\mathcal{M}_f(x)(s) = \int_0^\infty dx \, x^{s-1} f(x).$$  \hspace{1cm} (8)

There are two imaginary solutions to Eq. (7) given by

$$s = \pm is_0$$  \hspace{1cm} (9)

with $s_0 \simeq 1.0064$. Thus the solution to Eq. (5) is given by the linear combination of

$$a_{sc}(p) = c_+ p^{s_0} + c_- p^{-is_0}$$  \hspace{1cm} (10)

where $c_\pm$ are constants. In the above mentioned region, $1/a_2 \ll p \ll \Lambda$, the phase of $a_{sc}(p)$ is well determined

$$a_{sc}(p) = A \cos(s_0 \ln \frac{p}{\Lambda} + \delta),$$  \hspace{1cm} (11)

where $A$ and $\delta$ are some undetermined constants. It should be noted that the form of Eqs. (10,11) already suggests the underlying one dimensional periodic physics on which we will elaborate on in Sec. V. In addition the log periodic solution (11) is a known property of functions with a DSI. In the following section we will present, for the sake of clarity, a brief sketch of the properties of functions with DSI as a basis for establishing a connection to the three-body scattering amplitude.

### III. A BRIEF INTRODUCTION TO DISCRETE SCALING FUNCTIONS

To help express the scattering amplitude in terms of functions with a DSI we briefly digress in this section to describe the mathematical properties of functions with a discrete symmetry. The material in this section is a short summary of the introductory material found in Ref. [26] combined with Ref. [27]. In general a function with a discrete scale invariance will obey the following equation

$$f(x) = g(x) + \frac{1}{b} f(ax).$$  \hspace{1cm} (12)

Were $a$ and $b$ are scaling parameters and $g(x)$ an initial function. In describing physical systems Eq. (12) typically becomes exact only asymptotically, however for systems defined on a on regular geometrical fractals such as the Cantor set, the Sierpinsky Gasket, etc., it is exact on all scales for nearest neighbor interactions [28]. Thus functions satisfying Eq. (12) can usually be associated with a fractal structure.

The general solution to the above Eq. (12) is given by

$$f(x) = x^{\ln b / \ln a} G(\frac{\ln x}{\ln a})$$  \hspace{1cm} (13)

where $G(x)$ is a periodic function of, $x$, with period unity. A formal iterative solution for Eq. (12) is given in the form

$$f(x) = \sum_{n=0}^{\infty} b^{-n} g(a^n x).$$  \hspace{1cm} (14)
In the specific case where \( g(u) = \cos(u) \) were \( u = a^n x \) one obtains the most well known example of a continuous function which (for \( ab > 1 \)) is nowhere differentiable introduced by Weierstrass \[29\] and named after him

\[
W(x) = \sum_{n=0}^{\infty} \left( \frac{1}{b} \right)^n \cos(a^n \pi x). \tag{15}
\]

In the regime were the Weierstrass has a fractal structure one can associate with it a fractal dimension

\[
D_H = 2 + \frac{\ln b}{\ln a} \tag{16}
\]

For physical systems these sort of solutions, Eqs. (14\textsuperscript{15}) are usually considered as an asymptotic case obtained for expansions close enough to a fixed point [28]. Preforming a Mellin transform (defined in Eq. (8)), on Eq. (14) one obtains the zeta function for \( f(x) \)

\[
\zeta_f(s) = \frac{b a^s \zeta_g(s)}{1 - b a^s}. \tag{17}
\]

The zeta function has the following definition

\[
\zeta_f(s) = \frac{M_f(s)}{\Gamma(s)}, \tag{18}
\]

where \( \Gamma \) is the Euler Gamma function.

The pole structure of \( \zeta_f(s) \) in Eq. (17) is composed of poles of the analytical function \( g \) which generally occur for integer values and contribute only to the regular part of \( f \) and the poles resulting from the DSI which are given by the solutions \( s_n \) of

\[
ba^s = 1 \tag{19}
\]

Specifically

\[
s_n = -\frac{\ln b}{\ln a} + \frac{2\pi in}{\ln a} \tag{20}
\]

The \( n = 0 \) case gives the real power law solution \( f(x) = C x^\alpha \) to the homogeneous version of Eq. (12), i.e \( g(x) = 0 \), were \( \alpha = -\frac{\ln b}{\ln a} \) which from Eq. (16) can also be presented as \( \alpha = 2 - D_H \).

**IV. DESCRIBING THE SCATTERING AMPLITUDE IN TERMS OF A DSI FUNCTION**

Armed with the mathematics for DSI functions we can now return to the physics of the scattering amplitude, described in Sec [11] and attempt to reinterpret it in terms of self similar structures. Specifically it is of interest to find what the parameters \( a \) and \( \tilde{\lambda} \) which define the scaling in Eq. (12) are for the case of Efimov physics. Furthermore it is of interest to unmask the underlying fractal geometrical structure at the basis of the scattering amplitude.

**A. Introducing a condition on the Neumann series solution to the EFT integral equation**

In constructing a mapping between the integral equation for the scattering amplitude (3) to Eq. (12) which defines functions possessing a DSI symmetry, we start by formally considering the iterative solution to the integral Eq. (3) as a Neumann series as

\[
a_{sc}(p) = \sum_{n=0}^{\infty} \tilde{\lambda}^n \psi_n(p) \tag{21}
\]

where \( \tilde{\lambda} = 2\lambda/\pi \), \( \psi_n(p) = \int_0^\Lambda dk_1 \int_0^\Lambda dq_1 ... K(p,q_1)K(q_1,k)K(q_n,k) dq_1 ... dq_n \), and \( K(p,k) \) is defined by Eq. (4). Eq. (21) can be rewritten in the form of the iterative solution Eq. (14) for a DSI function under the following condition

\[
\int_0^\Lambda dq K(p,q) K(q,k) = \frac{2}{\sqrt{3}} K(a_c p, k), \tag{22}
\]
where \( a_e \) is a parameter, currently unfixed, which can later be identified with the corresponding DSI parameter in Eq. \( (12) \). The equality in condition Eq. \( (22) \) is evident when applying a Mellin transformation to both sides (see Eq. \( (27) \)). Essentially Eq. \( (22) \) is equivalent to the homogeneous form of Eq. \( (12) \) in terms of the Greens function since \( \int dq K(p,q)K(q,k) = K(p,k) \) and employing this in Eq. \( (22) \) one obtains

\[
K(p,k) = \frac{2}{\sqrt{3}} K(a_e p, k). \tag{23}
\]

Thus by comparing the above Eq. \( (23) \) to the homogeneous form of Eq. \( (12) \) one obtains the scaling parameter \( b \sim \sqrt{3}/2 \) (up to the \( \lambda^{-1} = \pi/2 \) factor). Alternatively under the condition in Eq. \( (22) \), Eq. \( (21) \) transforms to

\[
a_{sc}(p) = \sum_{n=0}^{\infty} \left( \frac{2\lambda}{\sqrt{3}} \right)^n \int_0^\Lambda dk K(a_e^{-n} p, k). \tag{24}
\]

From Eqs. \( (12,14) \) one can discern the scaling parameter \( b_e = \sqrt{3}\pi/4 \) and the periodic function

\[
g_e(p) = \int_0^\Lambda dk K(p,k), \tag{25}
\]

for the Efimov scattering amplitude. The index \( e \) was added to identify functions and parameters relevant to Efimov physics.

In Eq. \( (12) \) the two DSI scaling parameters \( a \) and \( b \) were assumed to be fixed defining the pole structure of the corresponding zeta function, Eq. \( (19) \). For the scattering amplitude for the Efimov physics these two parameters need to be inferred. Whereas the value of \( b_e \) is directly deduced from Eq. \( (24) \), the value of the parameter, \( a_e \), needs to be established from the pole structure of the corresponding zeta function. Since the Efimov scattering amplitude obeys a DSI symmetry its parameters obey Eq. \( (19) \) and since for Efimov physics \( s = \pm s_0 \) is fixed therefore \( a_e \) is automatically defined by \( b_e \) and \( s_0 \) as

\[
a_e = \exp \left( i \ln b_e / s_0 \right); \quad b_e = \frac{\sqrt{3}\pi}{4}. \tag{26}
\]

To obtain this result in a more rigorous manner, one starts out by multiplying both sides of condition \( (22) \) by \( p^s \) and integrating over \( p \) thus obtaining

\[
\frac{4}{3} \mathcal{M}_{h(p,q)}(s) \mathcal{M}_{h(q,k)}(s) = \frac{4}{3} a_e^{-s} \mathcal{M}_{h(p,k)}(s), \tag{27}
\]

where the l.h.s of the equation is obtained from the Mellin convolution theorem. The condition for the Efimov scattering amplitude stated in Eq. \( (7) \) can also be written as

\[
\mathcal{M}_{h(q,k)}(s) = \frac{1}{b_e}. \tag{28}
\]

Keeping in mind that \( \mathcal{M}_{h(x,y)} = \mathcal{M}_{h(y,x)} \), one obtains on inserting the above condition Eq. \( (28) \) into Eq. \( (27) \), exactly the condition for the pole structure of a DSI function defined in Eq. \( (19) \). However since this condition has to hold specifically for \( s = \pm s_0 \) the value of \( a_e \) is thus fixed, but in contrast to the DSI functions discussed in the previous Sec. \( III \) the parameter \( a_e \) for the scattering amplitude is complex. Furthermore one should note that the parameter \( a_e \) is also a function of the scale parameter \( b_e \) in difference to what is commonly the case as they are usually fixed independently. These properties have consequences regarding the self similar geometric structure which underlays the Efimov physics, as will be discussed shortly. As a side remark we note that the condition \( b_e a_e^{\pm s_0} = 1 \) for the Efimov states can be directly obtained from the self similar nature of the scattering amplitude, \( a_{sc}(a_e p) = b_e a_{sc}(p) \) by simply assuming a power law solution \( a_{sc}(p) \sim p^s \).

It is important to note that for the Efimov scattering amplitude, aside from the two poles \( s = \pm i s_0 \), the pole structure can take on the following values

\[
s_n = \pm i s_0 + \frac{2n\pi s_0}{\ln b_e}. \tag{29}
\]

This pole structure should be contrasted with the DSI pole structure introduced in Eq. \( (20) \) in which the real and imaginary terms are interchanged.
B. The corresponding Weierstrass function

Given the values of the DSI parameters Eq. (26) and the function series for the scattering amplitude, Eq. (24), we can proceed and demonstrate that the scattering amplitude can be expressed as a Weierstrass function Eq. (15). We begin by evaluating \( g_e(p) \) defined in Eq. (25) by estimating the sum in Eq. (24) by a saddle point approximation. Taking the derivative in terms of \( n \) and defining \( u = a_e^{-x} \) we obtain

\[
(\ln b_e)g_e(u) + (\ln a_e)ug_e'(u) = 0. \tag{30}
\]

Inserting the value of \( a_e = \exp (i \ln b_e / s_0) \) from Eq. (26) into the above Eq. (30) simplifies the expression to

\[
g_e'(u)g_e(u) = -\frac{i s_0}{u}. \tag{31}
\]

From which \( g_e(u) \) is obtained as

\[
g_e(u) = \exp \left(-\frac{i s_0}{u}\right) \tag{32}
\]

however a solution with the opposite sign is also admissible, Eq. (9), thus

\[
g_e(u) = 2 \cos \left(\frac{s_0 u}{u_0}\right). \tag{33}
\]

Moreover from the definition of \( K(p, k) \) in Eq. (4) one obtains that \( g_e(p) = g_e\left(\frac{1}{p}\right) \) and so we obtain

\[
g_e(u) = 2 \cos \left(\frac{u}{s_0}\right). \tag{34}
\]

By employing the above result Eq. (34), and inserting the value of \( g_e(p) \) into Eq. (24), with the definition of \( b_e \) from Eq. (26), the Efimov scattering amplitude is expressed by a Weierstrass function, Eq. (15)

\[
a_{sc}(p) = 2 \sum_{n=0}^{\infty} b_e^{-n} \cos \left(\frac{a_e^{-n} p}{s_0}\right) \tag{35}
\]

C. The underlying fractal structure

The DSI for the Efimov scattering amplitude is defined by the two scaling parameters Eq. (26). Each iterative transformation multiplies the function by a constant factor \( b_e = \sqrt{3\pi}/4 \) and introduces a phase \( a_e = \exp (i \ln b_e / s_0) \). It is natural to connect this symmetry to a one dimensional scattering system however such a mapping does not convey the full underlying geometric fractal like structure at the basis of the DSI. To uncover the relevant underlying geometry, one should extend the one dimensional form into the plane. Since the scale parameter \( a_e \) is complex it is convenient to consider the extension in term of polar coordinates. We consider the scaling parameter \( b_e \) as a radius vector which is a function of the angle \( b_e(\theta) \). As such this also introduces an angle dependence for \( a_e(b(\theta)) \). Since the periodicity requires \( a_e(\theta + 2\pi) = a_e(\theta) \) one obtains the following constraint on \( b_e \) such that

\[
\ln b_e(\theta + 2\pi) = \ln b_e(\theta) + 2\pi s_0. \tag{36}
\]

To obey the above restriction, Eq. (36), \( b_e \) should be of a logarithmic spiral form

\[
b_e(\theta) = b_0 e^{\theta s_0} \tag{37}
\]

where now \( b_0 = b_e \).

An alternative method to obtain the same result is obtained by considering Eq. (19) for \( s = i s_0 \). In this case the condition can be written as

\[
a_e^{s_0}b_e = 1. \tag{38}
\]

By the following representation \( a_e(\theta) = |a_e| \exp [i(\theta - \theta_0)] \) one obtains

\[
b_e e^{i s_0 \ln(|a_e| e^{i(\theta - \theta_0)})} = b_e e^{i s_0 \theta_0 |a_e| - s_0(\theta - \theta_0)}. \tag{39}
\]
functions on a one-dimensional lattice. In this reformulation the root of the zeta function, $s$, to demonstrate that under this different viewpoint a reinterpretation of the three-body physics can be given in terms of Bloch the periodic function $G$. The above solution Eq. (40) involves the two scales of the three-body physics, the short length scale physics is defined by the dimensional discrete lattice.

$k$-physics, Eq. (29), expressing these in terms of the lattice we consider the pole structure of a function obeying a DSI as defined in Eq. (20) and its analog in terms of Efimov physics, Eq. (29), was identified with the iterative solution for function obeying a DSI, Eq. (13), using the scaling parameters and transforming to a logarithmic variable $x = \ln p$

$$f(\tilde{x}) = e^{isk}G(\tilde{x}/L)$$

(41)

where we defined $k \equiv s/(\ln b_c/\ln a_c)$, $L = -s\ln a_e$ and $G(x)$ is a periodic function with period 1.

The similarities between the Efimov scattering amplitude, functions with a DSI and Bloch functions are stated in Tab. I. To better understand the correspondence between the Efimov scattering amplitude to the physics of a particle on a one-dimensional lattice we consider the pole structure of a function obeying a DSI as defined in Eq. (29) and its analog in terms of Efimov physics, Eq. (29), expressing these in terms of $k$ and $L$,

$$s = ik_0 + \frac{2\pi n}{L},$$

(42)

were the following identifications were considered

$$s_0 \leftrightarrow k_0$$

$$s_0/ln b_c = -i/ln a_e \leftrightarrow 1/L.$$
In this form the connection of \( s_n = (2\pi n s_0 / \ln b_e) \) to a crystal momentum is self-evident. It should be noted that whereas the pole structure for the DSI functions as well as for the Efimov scattering amplitude was obtained via a Mellin transform, the quasi-momentum for the Bloch states is obtained by a Fourier series expansion. However the two transforms can be connected if one considers the analytical continuation for the Mellin transform for a logarithmic variable.

The connection between the relevant underlaying symmetries, the DSI invariance of the Efimov physics to the translation symmetry of the one dimensional lattice system becomes clear by considering Eq. (43). One should note that considering a logarithmic variable, \( \ln p \), multiplication of the momentum \( p \) in the Efimov scattering amplitude by a constant \( a_e \), translates in terms of the logarithm variable, \( \tilde{x} = \ln \frac{p}{L} \) in Eq. (43) by \( \ln a_e \). This shift results only in a phase \( \exp (i k L) \) since the function \( G(x) \) in Eq. (41) is a periodic function with period 1. The phase, according to the identifications in Eq. (43), is \( s_0 L = \ln b_e \). Making it clear that requiring that the Efimov scattering amplitude as described in Eq. (41) be viewed as Bloch function on a lattice with a lattice period, \( L = \ln b_e/s_0 \) defined by the condition \( \psi(x + L) = \exp (i k L) \psi(x) \) is equivalent to requiring DSI symmetry. Thus identifying the scattering amplitude Eq. (41) with a Bloch function through the definitions in Eq. (43) leads directly to the connection between the two underlaying symmetries, i.e., multiplying \( p \) by \( a_e \) is equivalent to dividing or multiplying the function by \( b_e \) which exactly defines the DSI.

Having established the analogy to Bloch states one can now view the Efimov physics in terms of logarithmic variable \( \tilde{x} = \ln p \) as describing the physics of particle on a one-dimensional lattice, where \( L = \ln b_e \) plays the role of the lattice constant \( L \), and \( s_0 \) plays the role of the particles momentum. The power-law ansatz \( a_{sc}(p) \sim p^s \) suggested as a solution to Eq. (5) maps into a plane wave solution \( a_{sc}(\tilde{x}) \sim \exp (i s \tilde{x}) \) where \( s \) is limited to the values \( \pm i s_0 \).

To make this analogy more explicit we consider the scattering amplitude, Eq. (11), expressed in terms of the logarithmic variable \( \tilde{x} = \ln p \) we can now reinterpret it in terms of a Bloch state

\[ a_{sc}(p) = A \cos(s_0 \ln \frac{p}{\Lambda} + \delta) \rightarrow a_{sc}(\tilde{x}) = A \cos(\kappa \tilde{x} + \delta'), \]

where \( \delta' \) is a phase. In this representation where the incoming momenta (in the Efimov description) plays the role of the spatial coordinate and \( s_0 \) plays the role of an effective crystal momentum.

### B. Obtaining the Efimov spectrum from the Bohr-Sommerfeld quantization

Employing the connection between Efimov physics to Bloch functions and having identified the corresponding momentum through Eq. (43), the Efimov spectrum can now simply be obtained from the Bohr-Sommerfeld quantization rule

\[ s_0 \int_{\tilde{x}_1}^{\tilde{x}} d\tilde{x} \equiv (n + \delta)\pi, \]
FIG. 1: Starting with the wave function for the Efimov states in real space transforming to momenta space and considering the scattering amplitude the logarithmic spiral self similar geometry is obtained. Transforming to exponential coordinates maps the physics into the physics of Bloch states on a one-dimensional lattice.

integration and employing the viral theorem we obtain the Efimov spectrum

\[ E_n = -\frac{p^2}{2m} e^{-2\pi n/s_0}, \]  

where \( p_* = e^{-\delta \pi / s_0} \ln \tilde{x}_1. \)

VI. REAL SPACE FORMALISM

In this section we analyze Efimov physics in real space thus we are able to connect it with the physics of the relativistic atomic collapse which is defined through the same fractal geometry, that of a ray across a logarithmic spiral.

A. The Efimov connection to DSI in real space

In considering an operator with a Weierstrass spectrum \( \gamma^n \) where \( n \) is an integer it was shown \[30\] that the Schrödinger equation for the inverse square potential of the form

\[ U(x) = -\frac{A}{x^2} \]

has an infinitely deep spectrum with states clustering at \( E = 0 \)

\[ E_n = -E_0 \gamma^n \]

referred to as a Weierstrass spectrum. When one requires that two solutions with energies \( E_1, E_2 \) are orthogonal the ratio between these energies is given by

\[ \frac{E_1}{E_2} = \exp \left( \frac{2\pi n}{\sqrt{A - \frac{1}{4}}} \right), \]

where \( n \) is an integer. To obtain the Weierstrass spectrum, Eq. \[48\] the constant \( A \), in Eq. \[47\], defining the potential takes the value

\[ A = \frac{1}{4} + \frac{4\pi^2}{\ln^2 \gamma}. \]
The above result relates directly to Efimov physics since in the real space calculations using hyper-spherical coordinates for the three body problem Efimov physics emerges from a Schrödinger equation with an inverse squared potential \[ (19) \]. Given for convenience in coordinates in which \( \hbar = 1 \)

\[
- \frac{1}{2\mu} \left[ \left( \frac{d^2}{dR^2} \right) + \frac{s_0^2 + 1/4}{R^2} \right] \psi(R) = E \psi(R) \tag{51}
\]

where \( R \equiv \frac{2}{3}(r_{12}^2 + r_{13}^2 + r_{23}^2) \), and \( r_{ij} \) are the relative particle coordinates \( \mu \) is the effective mass and \( E \) is the energy of the bound state. Comparing Eqs. (47),(50) to the above Eq. (51) one obtains the following identification

\[
s_0 \leftrightarrow \pm \frac{2\pi}{\ln \gamma}. \tag{52}
\]

Considering a semi-classical type solution using units in which the mass of the particles is \( m = 1 \) \[31\] the action given by

\[
S = \pm i \int_{R_0}^{R} dR' k(R') \tag{53}
\]

where \( k(R) = \sqrt{[E - V(R)]} \), and \( V(R) = (s_0^2 + 1/4)/R^2 \) which can be identified with \( U(x) \) in Eq. (47) by employing the connection in Eq. (52) and applying it to Eq. (50). In the region of small \( R \) where \( E \) can be neglected the boundary conditions for the integral are given by the turning point \( R_0 \) which are the roots of \( s_0^2 + 1/4 = 0 \).

\[
\psi(R) \approx A_+ e^{(1/s_0)\ln R} + A_- e^{(-1/s_0)\ln R} \tag{54}
\]

where \( A_+ \) and \( A_- \) are constants.

According to the semi-classical Bohr-Sommerfeld approximation for the phase difference between the two cases should be quantized such that

\[
2s_0 \ln(R) = 2\pi n \tag{55}
\]

The Bohr-Sommerfeld condition, Eq. (55), thus defines the discrete periodicity of \( k(R) \sim \ln R \) which is at the heart of Efimov physics and DSI functions. The above condition Eq. (55) is equivalent to Eq. (45) and hence also leads to the spectrum in Eq. (46).

Similar physics is described in Ref. \[32\] in which the problem of atomic collapse in the relativistic regime is analyzed. It is worth mentioning since in this case the spiral geometry is clearly evident. The collapsing trajectories for an electron into the nucleus are best defined through the quasi-classical radial momentum equation.

\[
p_R^2 = v_F^{-2} \left( E + \frac{Ze^2}{R} \right)^2 - \frac{M^2}{R^2} \tag{56}
\]

where \( R \) is the radial distance to the nucleus \( p_R \) is the radial momentum, \( e \) the electron charge, \( Z \) is the atomic number, \( M \) the electron angular momentum and \( v_F \) the Fermi velocity. The spiral trajectories are directly manifest in the atom collapse for the case \( M < Ze^2/c \) for \( E > 0 \) and the ray across the spiral is manifested for the tunneling case in which \( M < Ze^2/c \) for \( E < 0 \). The resulting spectrum for the problem is equally spaced on a log scale

\[
E_n \approx \frac{Ze^2}{r_0} e^{-\pi \hbar n/\gamma} \tag{57}
\]

where \( r_0 \) is a lattice cut-off, \( \gamma = (M_e - M^2)^{1/2} \) and \( M_e = Ze^2/v_F \) is the critical angular momentum separating the falling trajectories from the stable trajectories.

It should also be noted that the Efimov physics is a special case in a more general set of problems which involve a singular inverse square potential. This set of equations also has a very similar dependence on a critical scale as the relativistic atomic collapse case, such that in order to obtain a discrete energy spectrum it is needed that in the potential, Eq. (47), \( A > A_{cr} \) where \( A_{cr} = (d - 2)^2/4 \) and \( d \) is the dimension of the problem. Stated this way the discrete spectrum is given by

\[
E_n \propto e^{2\pi n/\Lambda} \tag{58}
\]

where \( \Lambda = \sqrt{A - A_{cr}} \) and the results where presented for units such that \( \hbar = 1 \).
Efimov physics has been shown to be of importance to a wide set of physical problems ranging from ultracold atomic gases through nuclear physics to recently condensed matter systems as well as to biological systems. On the theoretical side it has even been considered for more than three particles for which it was originally formulated. In this work we have examined the less studied aspects of the geometric and more specifically the fractal properties of the Efimov scattering amplitude. Whereas initially it was known from the start that the Efimov spectrum forms a geometric series corresponding to an infinite number of weakly bound states which posses a discrete scale invariance, later also connected to a limit cycle RG limit, here we have demonstrated how one can apply the mathematical formalism for functions with DSI to the Efimov scattering amplitude. There are however some differences, in contrast to the theory described for functions possessing DSI symmetry in which one considers the two scaling parameters and as independent and fixed from the geometry determining the value of the zeroth pole of the corresponding zeta function, in the case of Efimov physics is imaginary and is obtained as a solution for a transcendental equation and is fixed and real. Solutions can then be found by considering complex values for . Using the DSI mathematical formalism we identified the relevant scaling parameters and established the corresponding Weierstrass function.

A fractal is an iterative structure. Famous examples are the triadic Cantor set obtained iteratively by dividing a segment into there parts removing the middle third part and continuing the process with the remaining segments. Another example is the Sierpinski gasket in which an equilateral triangle is subdivided recursively into smaller equilateral triangles. In regards to the Efimov scattering amplitude we have shown that the relevant fractal structure is a logarithmic spiral which is obtained by rotating by and stretching thus leaving the shape invariant. From the physics stand point Efimov physics is an example of a scale anomaly where the classical system posses a continuous symmetry which is broken at the quantum level to a discrete symmetry. In terms of our reformulation of the problem a new connection between the physical symmetry of the system to a scale anomaly where the classical system posses a continuous symmetry which is broken at the quantum level to a discrete symmetry. The self similarity of the scattering amplitude for Efimov physics expressed geometrically through the logarithmic spiral turns into translation invariance up to a phase when transforming into a logarithmic variable allowing the mapping of the complex Efimov physics to that of a particle on a one-dimensional lattice. The mapping allowed us to obtain the Efimov spectrum from the Bohr-Sommerfeld quantization rule. Returning to the field theoretic treatment one can now understand the mapping to the one dimensional lattice already through the integral Eq. which is obtained by summing over all terms in the perturbation theory. The fact that all term contribute “equally” (up to a phase) can be viewed as a scattering by a one dimensional lattice in which every scattering events introduces a phase.

We believe the connections presented in this work offer many possible venues for extension. Specifically we speculate that through the mapping of Efimov physics to that of a one dimensional lattice a possible connection between the Efimov three body parameter to the geometrical Zak phase for electrons on a one dimensional lattice could be established. From a mathematical point of view the underlying spiral identified as the underlying fractal structure for the Efimov scattering amplitude might have subtle connections to the Poincaré equation.

E.P wishes to thank Gerald Dunne, Eric Akkermans and Alexander Teplyaev for enlightening discussions on the mathematics of DSI and Vasili Kharchenko and Jia Wang, for very valuable discussions of Efimov physics and especially thank Luke Rogers for the spiral mapping idea. E.P acknowledges the kind hospitality of the Physics Department of the University of Connecticut in which this work originated.
