(Dated: December 12, 2016)

We derive a model of dark energy which evolves with time via the scale factor. The equation of state \(\omega = (1 - 2\alpha)/(1 + 2\alpha)\) is studied as a function of a parameter \(\alpha\) introduced in this model. In addition to the recent accelerated expansion, the model predicts another decelerated phase. The age of the universe is found to be almost consistent with observation. In the limiting case, the cosmological constant model, we find that vacuum energy gravitates with a gravitational strength, different than Newton’s constant. This enables degravitation of the vacuum energy which in turn produces the tiny observed curvature, rather than a 120 orders of magnitude larger value.

Keywords: Dark energy, cosmological constant, vacuum energy, accelerating universe.

I. INTRODUCTION

One of the most challenging issue in the history of physics is the implication of the supernovae data that the cosmic expansion is now accelerating [1–4]. Since then, the simple model of the cosmological expansion became insufficient, and efforts have been made for a deep understanding of the origin of this cosmic acceleration by trying to connect theory with observation. Other important observational data, is the evidence from the measurement of the cosmic microwave background (CMB) that besides matter, more than 68% of the energy density of the universe is dark energy [5].

The simplest and well known explanation is the need to invoke a cosmological constant, a very small and constant amount of energy with enough negative pressure which acts as repulsive force and causes the accelerated expansion. Although this appears to explain the cosmic acceleration, it suffers by the problem of reconciliation of the observed and theoretical energy density, this was called the cosmological constant problem (CCP) [6, 7]. This has opened the window to dynamical dark energy rather than matter (or radiation) as in [10].

In this paper, we apply the field equations obtained in [10] to cosmology, in the case of symmetric connection. The obtained perfect fluid is interpreted as variable dark energy rather than matter (or radiation) as in [10]. This dark energy will be derived to be evolving with time via the scale factor. The ratio of pressure to energy density, the so called equation of state parameter \(\omega\), is studied as a function of another parameter \(\alpha\) as \(\omega = (1 - 2\alpha)/(1 + 2\alpha)\) and thus we discuss a two possible decelerated and accelerated phases of the universe.

We will also study the limiting case of this model which is the conventional cosmological constant model. We will discuss the possible degravitation of the vacuum energy which produces the tiny observed curvature.

This paper is organized as follows: In section II, we briefly review the model given in [10]. In section III, we derive the behavior of the dark energy via the scale factor and discuss the decelerated and accelerated phases as well as the age of the universe. In section IV, we discuss the idea of degravitating the cosmological constant from this model. We give our summary in section V.

II. THE MODEL

The spacetime of General Relativity is considered to be plunged into a larger eight dimensional space which has a hypercomplex structure [10] [12]. As a result of this construction, in addition to a general asymmetric connection, the space became endowed with a new antisymmetric tensor of rank (2,1), denoted \(\Lambda^\alpha_{\beta\gamma}\). A general energy momentum tensor of a perfect fluid is derived when this
tensor is proposed to have the form \[ \Lambda_{\alpha\beta}^\gamma = g^{\gamma\rho} \epsilon_{\beta\gamma\alpha\rho} U^\rho, \] (1)

where \(\epsilon_{\beta\gamma\alpha\rho}\) is the Levi-Civita tensor and \(U^\rho\) is an arbitrary four vector.

The field equations are derived from variational principle applied to the following action \[ S = \int \sqrt{-g(R - \Lambda)} d^4 x, \] (2)

where the scalar \(\Lambda\) is defined as

\[ \Lambda = g^{\alpha\beta} \Lambda_{\alpha\beta}^\gamma \Lambda_{\gamma\beta}^\delta = 6g^{\mu\nu} U_\mu U_\nu. \] (3)

We should mention that this form of the scalar \(\Lambda\) given in \[10\] is not an ad hoc term, in fact that is the structure of the spacetime manifold which is considered as plunged into an eight dimensional manifold which leads to the presence of this scalar in the Lagrangian. For more details about the mathematical structure that leads to the action \[2\], we refer the reader to the papers \[10, 11\].

Following the same steps in \[10\], the vector \(U_\mu\) can be an arbitrary function of the metric (or \(g = \det g_{\mu\nu}\)) and coordinates. We propose the particular form for this vector \(U\) as in \[10\]

\[ U_\mu = (-g)^{-\alpha/2} p_\mu, \] (4)

where \(\alpha\) (noted \(g\) in \[10\]) is a real parameter, \(p_\mu\) is a vector density (not a vector), these two quantities are locally only functions of coordinates of the manifold and are defined such that \(U_\mu\) is a vector.

Now variation of the action \[2\] with respect to the metric tensor gives the field equations

\[ R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R - 6 U_\mu U_\nu + (3 - 6\alpha) U^2 g_{\mu\nu} = 0, \] (5)

with \(U^2 = g^{\mu\nu} U_\mu U_\nu\). In terms of unitary vectors, one can put

\[ U_\mu = \lambda u_\mu, \] (6)

where \(\lambda\) is real and \(g^{\mu\nu} u_\mu u_\nu = 1\), then the field equations become

\[ R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R - 6 \lambda^2 u_\mu u_\nu + (3 - 6\alpha) \lambda^2 g_{\mu\nu} = 0. \] (7)

As we see from these equations, one can always define a geometrical energy-momentum tensor of a perfect fluid as

\[ T_{\mu\nu} = 6\lambda^2 u_\mu u_\nu - (3 - 6\alpha) \lambda^2 g_{\mu\nu}, \] (8)

where we took \(8\pi G_N = 1\).

This allows us to define an energy density and pressure of this perfect fluid as \[10\]

\[ \rho = 3\lambda^2 (1 + 2\alpha), \quad p = 3\lambda^2 (1 - 2\alpha). \] (9)

One can also write

\[ p = \left( \frac{1 - 2\alpha}{1 + 2\alpha} \right) \rho. \] (10)

The above model has been derived in \[10, 12\] and the quantities found in equation \[9\] are interpreted as energy density and pressure of matter (and radiation).

Next, by assuming that matter is not a geometric quantity, we shall interpret the quantities given in \[10\] as the energy density and pressure of dark energy.

### III. EQUATION OF STATE AND AGE OF THE UNIVERSE

In this section, we will derive the evolution of the dark energy density (as well as pressure) in terms of the cosmological scale factor \(a(t)\). As in standard cosmology we apply the covariant conservation law to the energy momentum tensor \[8\]. In the flat Friedmann Robertson Walker spacetime, this law (continuity equation) gives

\[ (1 + 2\alpha) \dot{\lambda} + 3 \dot{\lambda} \lambda = 0, \] (11)

which can be solved easily as

\[ \lambda = \lambda_0 \left( \frac{a}{a_0} \right)^{-\frac{3}{1 + 2\alpha}}, \] (12)

where \(a_0\) is the scale factor at present and \(\lambda_0 = \lambda(a_0)\) is a constant.

Now the energy density given in \[11\] which we interpret here as dark energy density, takes the form

\[ \rho^{DE} = 3\lambda_0^2 (1 + 2\alpha) \left( \frac{a}{a_0} \right)^{-\frac{3}{1 + 2\alpha}}, \] (13)

where one can put \(\rho^{DE}_0 = 3\lambda_0^2 (1 + 2\alpha)\), the Dark Energy density when \(a = a_0\). The pressure is now given by its relation with the energy density \[10\].

As we see, this model describes dark energy which evolves with time via the scale factor, which does not decay faster than matter \(\rho^M \sim a^{-3}\), in the recent accelerated phase given by its conditions on \(\alpha\) that we will see later.

The ratio of pressure to energy density, i.e; the equation of state parameter \(\omega = p/\rho\) gives a useful description for dark energy. For this model described by the energy density and pressure given by \[12\], the equation of state parameter is written as

\[ \omega = \frac{1 - 2\alpha}{1 + 2\alpha}. \] (14)

As we see from this expression, for very big \(\alpha\), this model coincides with the standard cosmological constant constant model where \(\omega = -1\). Here, cosmological constant means a term \(\Lambda\) (may not be constant) which appears in Einstein’s equations as \(\Lambda g_{\mu\nu}\). Later in this paper, we
will study the case of a strictly cosmological constant obtained here from the field equations (7) when \( \alpha \) is very large.

From the expression (14), one can expect different phases depending on the chosen values of the real parameter \( \alpha \). The equation of state parameter (14) is plotted in Figure 1 for some values of \( \alpha \).

As one can see from the figure, the accelerating phase \( \omega < -1/3 \) is for \( \alpha > 1 \). The case \( -1/2 < \alpha < 1 \) corresponds to a decelerating phase \( \omega > -1/3 \), while acceleration vanishes, i.e; \( \omega = -1/3 \) for \( \alpha = 1 \).

We should mention that this study is made for a universe dominated by only dark energy. In standard cosmology, the accelerated and decelerated universes correspond to some specific relations between matter and dark energy. In fact, for the simple model of dark energy described by a cosmological constant, the decelerated phase corresponds to the era in which the matter energy density \( \rho_M \) was bigger than about 2\( \rho_{DE} \), and the universe started accelerating when \( \rho_M \) became less than 2\( \rho_{DE} \).

In our model, the above relations between matter and dark energy densities in the decelerated and accelerated eras are different from the standard cosmological constant model. In fact, in the presence of both matter and dark energy, one can write the second Friedmann equation in this case as

\[
\frac{\ddot{a}}{a} = -
\frac{4\pi G_N}{3}
\left[
\rho_M + \frac{4(1 - \alpha)}{1 + 2\alpha} \rho_{DE}
\right],
\]

where we have used relation (10) for dark energy. As we see from (15), for very large values of \( \alpha \), the second term in the right hand side becomes \(-2\rho_{DE}\), and then we get the cosmological constant model discussed above. In contrast to the standard cosmological constant model, as we see from equation (15), the decelerated and accelerated phases correspond respectively to matter energy density greater and less than the quantity \( \frac{4(1 - \alpha)}{1 + 2\alpha} \rho_{DE} \), rather than 2\( \rho_{DE} \). In the case \( \alpha = 1 \), only matter energy density appears in the right hand side of (14), which means that this case corresponds to a decelerated phase of the universe, this is not in contradiction with the previous study where acceleration vanishes for this case, because we have taken a universe dominated by only dark energy while here, matter is included.

In most of dark energy models one considers only the accelerated phase. Here in our model, the decelerated phase has its origin from the form of the energy momentum tensor (8) where its first term behaves as a matter term.

As we have seen so far, the phases of the universe are studied in this model as a function of the real parameter \( \alpha \) which unfortunately the model does not offer a mechanism to fix it. This opens the problem of the nature of this parameter and its dependence on the physical parameters for instance time and temperature which are the best physical parameters that can be used to study the epochs of the universe.

In the simplest model for a spatially flat universe filled with only matter, the age of the universe is \( t_0 = \frac{\pi}{3} H_0^{-1} \) billion years which is found to be shorter than the ages of some oldest stars in globular clusters, 12 \( \leq \) \( t_0 \) \( \leq \) 15 billion years [14]. This age problem is solved by introducing the conventional cosmological constant to be \( t_0 \sim H_0^{-1} \) billion years [2].

As we shall see later, the model given here predicts the same age as in the cosmological constant model where the universe is supposed to be dominated by dark energy. The solution of the first Friedman equation in this model is

\[
a(t) = a_0 \left[ 1 + \frac{3}{1 + 2\alpha} \sqrt{\frac{8\pi G_N}{3} \rho_{DE}^0} (t - t_0) \right]^{\frac{1 + 2\alpha}{1 + 3\alpha}},
\]

where we have used the dark energy density

\[
\rho_{DE} = \rho_{DE}^0 (a/a_0)^{1 + 3\alpha}. \tag{17}
\]

If we include matter in addition to dark energy, one may easily solve the first Friedman equation, and obtain the age of the universe in terms of the parameters \( \Omega_m \), \( H_0 \) and \( \alpha \) as follows

\[
t_0 = \frac{H_0^{-1}}{1 - \Omega_m} \sqrt{\frac{\pi}{6} \rho_{DE}^0} \int_1^0 \frac{dx}{x^2 \sqrt{(1 - \Omega_m)x^{-3} + 1}}. \tag{18}
\]

For the accelerating case, i.e, the range \( 1 \leq \alpha \leq \infty \), the last relation gives an age for the universe 0.80\( H_0^{-1} \leq \) \( t_0 \leq 1.12H_0^{-1} \), for \( \Omega_m \simeq 0.31 \). Recent results estimate the age of the universe to be 13.7 billion years [2], which is in the range obtained here.

We conclude this section by stating that models of a varying cosmological constant similar to our model have
been considered by some authors. In most of these models, the form of the cosmological constant was proposed (ad hoc) for some cosmological reasons \cite{13,15}, while in this paper, we derived it from geometry.

IV. GRAVITATIONAL CONSTANT AND THE COSMOLOGICAL CONSTANT PROBLEM

The model studied above is a general framework of variable dark energy which allows us to study different phases of the universe depending on the free parameter $\alpha$ which determines the equation of state $\omega$.

As we have mentioned during this study, a cosmological constant term can be obtained as a limit of our model for a very large $\alpha$. In fact, in this case the field equations \cite{7} become

$$R_{\mu\nu} - \frac{1}{2}g_{\mu\nu}R \simeq 6\alpha\lambda^2 g_{\mu\nu}.$$ \hfill (19)

In terms of strictly 'constant' cosmological constant, these equations can be written as

$$R_{\mu\nu} - \frac{1}{2}g_{\mu\nu}R = \lambda^2 \Lambda g_{\mu\nu},$$ \hfill (20)

where we have defined a cosmological constant $\Lambda = 6\alpha$ (independent from the scalar $\lambda$). In terms of the vacuum energy density $\rho^{vac} = \Lambda M^2_{Pl}$, where $M_{Pl} = (8\pi G_N)^{-1/2}$ is the Planck Mass, the last equation is written as

$$R_{\mu\nu} - \frac{1}{2}g_{\mu\nu}R = \left(\frac{M_{Pl}}{\lambda}\right)^2 \rho^{vac} g_{\mu\nu}.$$ \hfill (21)

In this case, we have $p \simeq -\rho$ (cosmological constant), and the continuity equation is solved as $\lambda = \lambda_0$ (a constant) rather than solution (12). Nevertheless, this is also clear from the solution (12) when $\alpha$ is large enough.

In general relativity, ordinary matter and vacuum energy gravitate with Newton’s constant. For the material part, this is supported and confirmed by experiments and observations, both at the solar system and the cosmological scales.

However, vacuum energy, originated from zero point energies of quantum fields as well as phase transitions, makes a perplexed problem when seen in the framework of general relativity. The zero-point energies of quantum fields are of the order $\Lambda_{UV}$, where $\Lambda_{UV}$ is the Ultra-Violet Cutoff. The spacetime curvature is very sensible to this quantity, in fact, if we trust quantum field theory up to Planck scale, i.e., $\Lambda_{UV} = M_{Pl}$, the scalar curvature that corresponds to this vacuum is $R^{theo} \sim M^2_{Pl}$. This theoretical value, estimated from ground states of particle fields, severely contradicts the observed curvature $R^{obs} \sim 10^{-47}$eV$^2$. This discrepancy, which is about 120 orders of magnitude between theory and observation is the origin of the cosmological constant problem.

In terms of mass scales, and for no physical reason, the related observed vacuum energy density is of the order of the Neutrino mass density, and the mentioned scalar curvature is given as

$$R^{obs} \sim \frac{m^4_{\nu}}{M^2_{Pl}},$$ \hfill (22)

where $m_{\nu} \simeq 10^{-3}$eV is the Neutrino mass.

Although the theoretical value of the vacuum energy is estimated from quantum field theory, the cosmological constant problem resides essentially in general relativity where this vacuum gravitates with Newton’s constant. In the present model and for this limit described by the field equation (21), this requirement imposes with no physical reason, $\lambda_0 = 1$. However, it is only observational bounds on the curvature $R^{obs}$ that determine the correct value of this constant. A value $\lambda_0 \neq 1$ translates the De-gravitation of the cosmological constant; unlike ordinary matter, vacuum does not gravitate with Newton’s constant.

Dirac large number hypothesis implies reasonable form of the constant $\lambda_0$ due to the very tiny observed curvature. This form might be a ratio of two hierarchically mass scales \cite{9}. At that end, this ratio can be written as

$$\lambda_0 = \frac{M_{Pl}}{M_{Co}},$$ \hfill (23)

where we have proposed the new cosmological strength $M_{Co}$ in addition to the fundamental gravity mass scale $M_{Pl}$.

Thus, the observational bound on the curvature (22) and the form of this later in terms of the theoretical cosmological constant $\Lambda$ lead to the following constraint on $M_{Co}$ \cite{16,17}

$$M^2_{Co} \simeq \Lambda \left(\frac{M_{Pl}}{m_{\nu}}\right)^4.$$ \hfill (24)

This shows clearly that the cosmological constant gravitates with $M_{Co}$, where for the larger value $\Lambda = M^2_{Pl}$, this mass scale is the mass of the universe \cite{16,18}. It is this case that fixes correctly the constant $\lambda_0$, in fact, from equations (23) and (24) we get

$$\lambda_0 = \left(\frac{m_{\nu}}{M_{Pl}}\right)^2.$$ \hfill (25)

In the recent years, degravitating the cosmological constant became of great interest. Unlike ordinary matter which gravitates with the Newton’s gravitational constant, vacuum energy is considered to gravitate with different cosmological strengths \cite{16,18}. Although they lack a real mechanism to derive the new cosmological strengths, these models (including the one given in this paper) enable degravitation of the cosmological constant, such that vacuum energy produces the observed tiny curvature due to hierarchy between different mass scales rather than fine-tuning.
V. SUMMARY

In this paper, we have studied a model with variable dark energy. This model is derived from a geometrical construction used by some authors as an attempt to generalize the unified theory of Einstein-Schrodinger. Unlike the interpretation given in that work, we have interpreted here the obtained energy momentum tensor as dark energy.

We have studied some cosmological consequences of this model where dark energy is found to be evolving with time via the scale factor. Unlike most of dark energy models where the studies are restricted only to the accelerated expansion, here the model predicts another decelerated phase of the universe. The reason is an additional term that appears in the energy momentum tensor, in addition to the cosmological term. The equation of state $\omega$ is found to depend on a real parameter $\alpha$ and the condition of accelerating and decelerating phases has been studied as a function of this parameter. The model does not offer a mechanism to fix this parameter which we believe should depend on some of the physical parameters such as time and temperature.

We have studied the limiting case which is the cosmological constant model. We found that vacuum energy can be degravitated, in other word unlike matter and radiation which gravitate with Newton’s constant, vacuum energy in this model gravitates with a different gravitational strength which is fixed here using observational considerations. As a result, vacuum energy which receives its value from zero-point energies of quantum fields as well as early time phase transitions, curves the empty space by a tiny amount consistent with the observed value.
