Adipose-derived stem cells weigh in as novel therapeutics for acute lung injury

MSCs include bone marrow-derived stem cells (BMSCs), MSCs in umbilical cord blood, and adipose-derived stem cells (ASCs). In the field of ALI/ARDS cell-based therapeutics, most attention has focused on BMSCs, which have therapeutic efficacy in rodent and human tissue models of ALI and sepsis [3,4]. However, a number of barriers that may limit the clinical usefulness of BMSCs in human ALI/ARDS have been identified [5,6] (Table 1). Like BMSCs, ASCs have anti-inflammatory and immuno-suppressive activities. ASCs inhibit immune cell activation and proliferation by inducing cell-to-cell contact and signaling and releasing mediators that limit tissue injury [7]. ASCs have greater anti-inflammatory potential than BMSCs because they secrete higher levels of bioactive mediators [8]. This and other properties of ASCs (Table 1) make them an attractive alternative to BMSCs as cell-based therapeutics for human ALI/ARDS. Consistent with this concept, recent studies have shown that transplantation of autologous ASCs attenuates ischemia-reperfusion lung injury in rodents [9,10].

The paper by Zhang and colleagues [11] builds upon this literature by examining whether ASCs have efficacy in a model of direct ALI in mice. Zhang and coworkers challenged mice with bacterial lipopolysaccharide (LPS) by oropharyngeal route, and 4 h later ASCs isolated from syngeneic mice (mASCs) or humans (hASCs) were delivered to the mice by the same route, and ALI severity was assessed 24 and 72 h later. The LPS-challenged and mASC- or hASC-treated mice lost less body weight, and had decreased alveolar-capillary barrier injury as assessed by broncho-alveolar lavage fluid albumin levels, and reduced alveolar septal thickening and exudates when compared with LPS-challenged mice not treated with ASCs. Treatment of the LPS-challenged mice with hASCs and mASCs also reduced polymorphonuclear neutrophil influx into the lungs, and suppressed lung levels of pro-inflammatory mediators. Murine ASCs increased lung levels of anti-inflammatory interleukin-10 in LPS-challenged mice.

A strength of the paper is its novel focus on ASCs as a therapy for ALI, and its approach to test ASCs therapeutically (rather than prophylactically) in an ALI model.
that induces robust neutrophilic lung inflammation. Additionally, the authors compared the therapeutic efficacy of human versus murine ASCs. While both hASCs and mASCs attenuated ALI, it is noteworthy that for most ALI parameters examined, mASCs were more potent than hASCs. However, it is possible that hASCs have greater potency at restraining acute lung inflammation in human subjects.

The study of Zhang and colleagues has several limitations that need to be addressed before ASCs can be advanced to human clinical trials. First, no single ALI animal model can completely reproduce all the pathologic features of human ALI/ARDS. While the LPS model studied by Zhang and coworkers induces robust neutrophilic lung inflammation, it causes only modest alveolar-capillary barrier injury, which is a hallmark of ALI/ARDS. Thus, it will be important to test the efficacy of ASCs in ALI models associated with severe ALI (such as hyperoxia and acid-induced ALI) and to assess the effects of ASCs on physiologic readouts of ALI, including lung compliance and hypoxemia. Second, ALI/ARDS in humans is often initiated by bacterial infections, but the model chosen (LPS-mediated ALI) causes sterile lung inflammation. Given that ASCs suppress immune responses, it will be important to assess their effects on host responses to pathogens that can cause ALI/ARDS. Third, the mechanisms by which ASCs produce their beneficial effects in this model were not addressed. Fourth, given that ARDS patients are often not treated within the first 4 hours of illness (the single time-point when ASCs were delivered to mice in this study), future studies should determine how late in the disease course ASCs can be delivered and still induce a protective effect and for how long this protective effect is sustained. Moreover, the long-term safety of delivering ASCs was also not assessed in this study. It is noteworthy in this respect that hASCs promote the growth of tumor cells [12]. Therefore, before ASCs can be used to treat human subjects, it will be necessary to investigate their long-term safety in animals.

**Conclusion**

The study by Zhang and colleagues provides evidence that ASCs have potential as novel cell-based therapeutics for ALI/ARDS. The next logical step towards advancing ASCs into human clinical trials for ALI/ARDS will be to further test ASCs for their efficacy and safety in additional small and large animal models of ALI, including models more clinically relevant than the LPS-mediated ALI model studied by Zhang and colleagues.

**Abbreviations**

ALI, acute lung injury; ARDS, acute respiratory distress syndrome; ASC, adipose-derived stem cell; BMSC, bone marrow-derived stem cell; hASC, human adipose-derived stem cell; LPS, lipopolysaccharide; mASC, mouse adipose-derived stem cell; MSC, mesenchymal stem cell.

**Competing interests**

KG, AH, and CAO have no financial or non-financial competing interests to declare in relation to this manuscript.

**Author’s contributions**

KG, AH, and CAO all contributed to the writing of this manuscript.

**Author’s information**

Kushagra Gupta, MD is a post-doctoral fellow; Anja Hergrueter is a research technician; and Caroline Owen, MD, PhD is an Assistant Professor of Medicine in the Division of Pulmonary and Critical Care Medicine at Brigham and Women’s Hospital in Boston and Harvard Medical School. Dr Owen is also a fellow at the Lovelace Respiratory Research Institute, Albuquerque, NM.

**Acknowledgements**

This work was supported by PHS grants #HL086814 and HL111835, and PO1HL105339, and The Brigham and Women's Hospital-Lovelace Respiratory Research Institute Consortium. These funding bodies had no role in the design or the writing of this manuscript or in the decision to submit the manuscript for publication.
