**ZZγ and Zγγ couplings at linear e^+e^- collider energies with the effects of Z polarization and initial state radiation**

S. Ata˘g and ˙I. S¸ahin

Department of Physics, Faculty of Sciences, Ankara University, 06100 Tandogan, Ankara, Turkey

The constraints on the neutral gauge boson couplings, ZZγ and Zγγ, are investigated at linear e^+e^- collider energies through the Zγ production with longitudinal and transverse polarization states of the final Z boson. Because of high energy of linear electron-positron beams, initial state radiation (ISR) considerably changes the production cross section. We obtain an increase in the cross section by a factor of 2-3 due to ISR for transverse polarization and by a factor of 10-100 for longitudinal polarization states depending on the energy.

We find the 95% C.L. limits on the CP conserving form factors h^Z_3, h^Z_4, h^\gamma_3 and h^\gamma_4 with integrated luminosity 500 fb^{-1} and \sqrt{s} =0.5, 1, 1.5 TeV energies. It is shown that the longitudinal polarization of the Z boson, together with ISR, can improve sensitivities by factors 2-3.

**I. INTRODUCTION**

The self interactions of the gauge bosons are consequences of the non-abelian structure of the electroweak sector of the Standard Model (SM). The study of the trilinear gauge boson couplings leads to important tests of electroweak interactions. Neutral gauge boson couplings ZZγ and Zγγ are not generated at tree level by the SM. Higher order loop level corrections are highly below the current experimental sensitivity \cite{1}. Nevertheless, the new physics with energy scale above present experimental threshold might provide tree level neutral triple-gauge boson couplings. Deviation of the couplings from the expected values would indicate the existence of new physics beyond the SM. Therefore precision measurements of triple vector boson vertices will be the crucial tests of the structure of the SM.

For the process e^+e^- → Zγ it is convenient to study the anomalous neutral triple gauge couplings ZγZ and Zγγ which obey Lorentz and gauge invariance. Within the formalism of Ref. \cite{1, 2} there are eight anomalous coupling parameters h^Z_i, h^\gamma_i (i = 1, ..., 4) which are all zero in the standard model. Here we are interested in CP-even couplings that are proportional to h^Z_i and h^\gamma_i (V = Z, γ). The photon and the Z boson in the final state are considered as on-shell particles while the third boson at the vertex, the s-channel internal propagator, is off-shell. Due to partial wave unitarity constraints at high energies, an energy dependent form factor ansatz can be considered:

\[
\begin{align*}
    h^V_i(s) &= \frac{h^V_i(0)}{(1 + s/\Lambda^2)^3} ; \quad i = 1, 3 \\
    h^V_i(s) &= \frac{h^V_i(0)}{(1 + s/\Lambda^2)^4} ; \quad i = 2, 4
\end{align*}
\]

In this work we assume that new physics scale Λ is above the collision energy \sqrt{s} and we neglect the energy dependence of the form factors in the energy region we are interested in.

CP conserving anomalous Z(p_1)γ(p_2)Z(p_3) vertex function can be written following the low energy parametrization of the residual effect from the effective lagrangian \cite{1, 2}:

\[
ig_e \Gamma^{\alpha\beta}Z\gamma(p_1, p_2, p_3) = ig_e \left( \frac{p_3^2 - p_2^2}{m_Z^2} \right) \left[ h^Z_3 \epsilon^\mu\nu\beta\sigma p_2^\mu p_2^\nu + \frac{h^Z_4}{m_Z^2} \epsilon^{\mu\nu\beta\sigma} p_3^\mu p_3^\nu p_2^\beta p_2^\sigma \right]
\]

where m_Z and g_e are the Z-boson mass and charge of the proton. The Zγγ vertex function can be obtained with the replacements:

\[
\frac{p_3^2 - p_2^2}{m_Z^2} \rightarrow \frac{p_3^2}{m_Z^2}, \quad h^Z_i \rightarrow h^\gamma_i, \quad i = 3, 4
\]
The overall factor $p_{Z}^{2}$ in the $Z\gamma\gamma^{*}$ vertex function originates from electromagnetic gauge invariance. Due to Bose statistics the $Z\gamma\gamma$ vertex vanishes identically if both photons are on shell (Yang’s theorem) \[2\].

Previous limits on the $Z\gamma Z^{*}$ and $Z\gamma\gamma^{*}$ anomalous couplings have been provided by the Tevatron $|h_{Z}^{\gamma}| < 0.36$, $|h_{Z}^{\gamma}| < 0.05$, $|h_{Z}^{\gamma}| < 0.37$ and $|h_{Z}^{\gamma}| < 0.05$ \[3\] and the combination of four LEP experiments ALEPH, DELPHI, L3, OPAL $-0.20 < h_{Z}^{\gamma} < 0.07$, $-0.05 < h_{Z}^{\gamma} < 0.12$, $-0.049 < h_{Z}^{\gamma} < 0.008$ and $-0.002 < h_{Z}^{\gamma} < 0.034$ \[4\] at 95% C.L. .

Based on the analysis of ZZ production at the upgraded Fermilab Tevatron and the CERN Large Hadron Collider (LHC) achievable limits on the $Z\gamma\gamma$ couplings ($f_{Z}^{\gamma^{*}}$, $f_{Z}^{\gamma}$) have been discussed \[5, 6\].

Research and development on linear $e^{+}e^{-}$ colliders at SLAC, DESY and KEK have been progressing and the physics potential of these future machines is under intensive study. In this paper, the process $Z\gamma\gamma \rightarrow Z\gamma\gamma$ based on the analysis of ZZ production at the upgraded Fermilab Tevatron and the CERN Large Hadron Collider (LHC) has been discussed.

Another important point is the polarization of the final state $Z$ boson. In order to determine the $Z$ polarization, we show that the angular distribution of the $Z$ decay products, has a clear correlation with the helicity states of the $Z$ boson.

\section{Cross Sections and Angular Correlations for Final State Fermions}

In this section, we present the cross section calculation via helicity amplitudes for the complete process $e^{+}e^{-} \rightarrow Z\gamma \rightarrow \ell^{+}\ell^{-}\gamma$ and describe angular distributions of final state fermions to see the correlations with the polarization states of $Z$ boson. Let us start with the differential cross section

$$
\frac{d\sigma(e^{+}e^{-} \rightarrow Z\gamma \rightarrow \ell^{+}\ell^{-}\gamma)}{d\ell^{+}\ell^{-}\gamma} = \frac{1}{2s} |M|^{2} \frac{d^{3}p_{a}}{(2\pi)^{3}2E_{a}} \frac{d^{3}p_{b}}{(2\pi)^{3}2E_{b}} \frac{d^{3}k_{2}}{(2\pi)^{3}2E_{\gamma}}(2\pi)^{4}\delta^{4}(p_{1} + p_{2} - p_{3} - p_{4} - k_{2})
$$

(5)

where $p_{1}, p_{2}$ are the momenta of incoming leptons, $p_{3}, p_{4}$ are the momenta of outgoing fermions and $k_{2}$ is the momentum of outgoing photon. $|M|^{2}$ is the square of the full amplitude which is averaged over initial spins and summed over final spins. The helicity dependent full amplitude can be expressed as follows

$$
|M(\sigma_{1}, \sigma_{2}; \sigma_{3}, \sigma_{4}, \lambda_{\gamma})|^{2} = \int \frac{d^{4}k_{1}}{(2\pi)^{4}} \sum_{\lambda_{Z}} M_{a}(\sigma_{1}, \sigma_{2}; \lambda_{Z}, \lambda_{\gamma})D_{Z}(k_{1}^{2})M_{b}(\lambda_{Z}; \sigma_{3}, \sigma_{4})^{2}
$$

$$
(2\pi)^{4}\delta^{4}(p_{1} + p_{2} - k_{1} - k_{2})(2\pi)^{4}\delta^{4}(k_{1} - p_{3} - p_{4})
$$

(6)

where $k_{1}$ is the internal momentum of the $Z$ boson propagator. $\sigma_{1}, \sigma_{2}$ are the incoming lepton helicities, $\sigma_{3}, \sigma_{4}, \lambda_{\gamma}$ are the outgoing fermion and photon helicities. For the summation over the intermediate $Z$ boson polarization we take the helicity basis $\lambda_{Z} = +, -, 0$. Here $D_{Z}(k_{1})$ is the Breit-Wigner propagator factor for the $Z$ boson

$$
D_{Z}(k_{1}) = \frac{1}{k_{1}^{2} - M_{Z}^{2} + iM_{Z}\Gamma_{Z}}
$$

(7)

Here $M_{a}(\sigma_{1}, \sigma_{2}; \lambda_{Z}, \lambda_{\gamma})$ is the helicity amplitudes for $e^{+}e^{-} \rightarrow Z\gamma$ with on shell $Z$ boson which are provided in the appendix. $M_{b}(\lambda_{Z}; \sigma_{3}, \sigma_{4})$ is the decay amplitude of the $Z$ boson which will be given later. Using the narrow width approximation differential cross section becomes

$$
\frac{d\sigma(e^{+}e^{-} \rightarrow Z\gamma \rightarrow \ell^{+}\ell^{-}\gamma)}{d\ell^{+}\ell^{-}\gamma} = \frac{1}{2s (2\pi)^{4}\Gamma_{Z}} \sum_{\lambda_{Z}} M_{a}(\lambda_{Z})M_{b}(\lambda_{Z})|^{2}
$$

$$
\frac{d^{3}k_{1}}{(2\pi)^{3}2E_{Z}} \frac{d^{3}k_{2}}{(2\pi)^{3}2E_{\gamma}}(2\pi)^{4}\delta^{4}(p_{1} + p_{2} - k_{1} - k_{2})
$$

$$
\frac{d^{3}p_{3}}{(2\pi)^{3}2E_{3}} \frac{d^{3}p_{4}}{(2\pi)^{3}2E_{4}}(2\pi)^{4}\delta^{4}(k_{1} - p_{3} - p_{4})
$$

(8)

Here $M_{a}(\lambda_{Z})$ and $M_{b}(\lambda_{Z})$ indicate average over initial lepton spins, summation over final state fermion spins and photon. In the rest frame of the $Z$ boson where the decay amplitudes are most simply expressed, we get
\[ d\sigma(e^+e^- \to Z\gamma \to \ell^+\ell^-\gamma) = \frac{1}{2s} \frac{1}{((2\pi)^2 16 M_Z \Gamma_Z)} \sum_{\lambda} M_a(\lambda Z) M_b(\lambda Z)^2 \]

\[ d^3k_1 \frac{d^3k_2}{(2\pi)^2 2 E_Z} (2\pi)^4 \delta^4(p_1 + p_2 - k_1 - k_2) d\cos\theta^* d\phi^* \]

where \( \theta^* \) and \( \phi^* \) are the polar and azimuthal angles of the final state leptons in the Z rest frame with respect to the Z boson direction in the \( \ell\ell\gamma \) rest frame. After integration over azimuthal angles \( \phi^* \) interference terms will vanish as below

\[ d\sigma(e^+e^- \to Z\gamma \to \ell^+\ell^-\gamma) = \frac{1}{2s} \frac{1}{(32\pi M_Z \Gamma_Z)} \left( |M_a(+)M_b(+)|^2 + |M_a(-)M_b(-)|^2 + |M_a(0)M_b(0)|^2 \right) \]

\[ d^3k_1 \frac{d^3k_2}{(2\pi)^2 2 E_Z} (2\pi)^4 \delta^4(p_1 + p_2 - k_1 - k_2) d\cos\theta^* \]

This can be written in a more compact form

\[ d\sigma(e^+e^- \to Z\gamma \to \ell^+\ell^-\gamma) = \frac{1}{(32\pi M_Z \Gamma_Z)} \left[ |d\sigma(+)M_b(+)|^2 + |d\sigma(-)M_b(-)|^2 + |d\sigma(0)M_b(0)|^2 \right] d\cos\theta^* \]

If one performs further integration over polar angle \( \cos\theta^* \) it turns out to be a well known result

\[ d\sigma(e^+e^- \to Z\gamma \to \ell^+\ell^-\gamma) = |d\sigma(+) + d\sigma(-) + d\sigma(0)|BR(Z \to \ell^+\ell^-) \]

\[ = d\sigma(e^+e^- \to Z\gamma)BR(Z \to \ell^+\ell^-) \]

Explicit forms of the decay amplitudes \( |M_b(+)|^2, |M_b(-)|^2 \) and \( |M_b(0)|^2 \) in the Z rest frame are given by

\[ |M_b(+)|^2 = \frac{M_Z^2}{2} [g_L^2 (1 - \cos\theta^*)^2 + g_R^2 (1 + \cos\theta^*)^2] \]

\[ |M_b(-)|^2 = \frac{M_Z^2}{2} [g_L^2 (1 + \cos\theta^*)^2 + g_R^2 (1 - \cos\theta^*)^2] \]

\[ |M_b(0)|^2 = M_Z^2 (g_L^2 + g_R^2) \sin^2\theta^* \]

\[ |M_b(TR)|^2 = |M_b(+)|^2 + |M_b(-)|^2 \]

\[ |M_b(LO)|^2 = |M_b(0)|^2 \]

By measuring the polar angle distributions of the Z decay products one can directly determine the differential cross sections for fixed Z helicities. In other words, Z helicity states are obtained from a fit to these distributions. Complete factors \((1/32\pi \Gamma_Z)|M_b(\lambda Z)|^2 \) in front of \( d\sigma(\lambda Z) \) in differential cross sections are plotted in Fig.1. As can be seen from Fig.1 longitudinal (LO) and transverse (TR) distributions are well separated from each other. This is why we consider only transverse and longitudinal polarizations for the Z boson in next sections.

### III. INITIAL STATE ELECTROMAGNETIC RADIATIVE CORRECTION

Due to small mass of the electron, a significant role is played by the electromagnetic radiative corrections to the initial electron-positron state especially at linear collider energies. In this work we use structure function formalism to describe the electromagnetic radiative corrections in \( e^+e^- \) colliders. The cross section can be written in the following form within this formalism

\[ \sigma(s) = \int dx_1 \int dx_2 \ D_1(x_1, Q^2) \ D_2(x_2, Q^2) \sigma'(s') \]
FIG. 1: Polar angle distributions of Z decay product \((1/32\pi \Gamma Z) |M_0(\lambda Z)|^2\) in the rest frame of Z boson for \(\lambda Z = -1, +1, 0\). Transverse polarization state is defined as the sum of +1 and -1 states.

\[|M_b(\lambda Z)|^2 \cos \theta^*\]

where \(\sigma'(s')\) is the cross section with reduced energy \(s' = x_1 x_2 s\). \(D_1(x_1, Q^2) (D_2(x_2, Q^2))\) stands for the electron (positron) structure function giving the probability of finding an electron (positron) within an electron (positron) with a longitudinal momentum fraction \(x_1 (x_2)\). Although several definitions of the structure functions are present we use the following ones which are used by HERWIG [8]

\[D_1(x, s) = \beta (1-x)^{\beta-1} g(x, s)\]
\[g(x, s) = e^{\beta(1+x/2)x/2} (1 - \beta^2 \pi^2/3) + y \beta^2 y[(1 + x)(1 + x)^2 + 3 \log x] - 4 \log x \]
\[
\begin{align*}
\beta &= \frac{\alpha_{em}}{\pi} \left( \log \frac{s}{M_e^2} - 1 \right), \quad y = [\beta(1-x)^{\beta-1}]^{-1} \\
\end{align*}
\]

To avoid divergency at the upper limit of the momentum fraction, \(x = 1\), the cross section can be transformed into different form

\[\sigma(s) = \int_0^{1-\epsilon} dx_1 \int_0^{1-\epsilon} dx_2 D_1(x_1, s) D_2(x_2, s) \sigma'(s') + \epsilon^2 g_2(1, s) \int_0^{1-\epsilon} dx_2 D_1(x_1, s) \sigma'(x_1 s) + \epsilon^2 g_1(1, s) \int_0^{1-\epsilon} dx_2 D_2(x_2, s) \sigma'(x_2 s)
\]

where \(\epsilon\) can be taken as \(10^{-9} - 10^{-12}\). In this region of \(\epsilon\) the cross section changes by a factor of 0.985. If one takes smaller \(\epsilon\) values, higher machine precision gives softer \(\epsilon\) dependence. The following transformation gives relatively smooth integrand

\[\int_0^{1-\epsilon} dx_1 \int_0^{1-\epsilon} dx_2 D_1(x_1, s) D_2(x_2, s) \sigma'(s') = \int_{E_{\text{min}}}^{E_{\text{max}}} dE \int_{F_{\text{min}}}^{F_{\text{max}}} dF g_1(x_1, s) g_2(x_2, s) \sigma'(x_1 x_2 s)\]
\[
x_1 = 1 - (-E)^{1/\beta}, \quad x_2 = 1 - (-E)^{1/\beta}
\]
\[
E_{\text{min}} = -(1 - \frac{\tau_{\text{min}}}{1 - \epsilon}), \quad E_{\text{max}} = -e^\beta
\]
\[
F_{\text{min}} = -(1 - \frac{\tau_{\text{min}}}{x_2}), \quad F_{\text{max}} = -e^\beta
\]
\[
\tau_{\text{min}} = \frac{M_Z^2}{s}
\]

Using above formalism we calculate the cross section with initial state radiative corrections for both Standard Model and anomalous coupling cases. In Fig.2 the effects of ISR to the total cross section for the standard model polarization. Here average over initial spins and sum over photon polarization are performed. The unpolarized cross amplitudes for transverse and longitudinal Z polarizations using the helicity amplitudes given in the appendix the LO and TR cross sections are different. In order to understand this feature let us write standard model squared LO cross section becomes sizable due to ISR. The reason for this comes from the fact that the energy dependences of for the TR case and a factor of 10-100 for LO polarization case depending on the energy. Furthermore, very small LO cross section becomes sizable due to ISR. The reason for this comes from the fact that the energy dependences of the LO and TR cross sections are different. In order to understand this feature let us write standard model squared amplitudes for transverse and longitudinal Z polarizations using the helicity amplitudes given in the appendix

\[
|M_a(TR)|^2 = 8[(C_3^L)^2 + (C_3^R)^2]\left(\frac{2}{\sin^2 \theta} - 1\right) \frac{(m_Z^2 + s^2)}{(s - m_Z^2)^2}
\]
\[
|M_a(LO)|^2 = 16[(C_3^L)^2 + (C_3^R)^2]\frac{m_Z^2 s}{(s - m_Z^2)^2}
\]

where \(M_a(\lambda_Z)\) is defined in Eq.(8) and we neglect electron mass. As can be seen here the longitudinal part is independent of the polar angle whereas the transverse part strongly depends on it. Angular integration implies that contribution of the transverse polarization always gives larger cross section than the longitudinal one. In both cases, the largest cross section comes from the energy region where \(\sqrt{s} \approx m_Z\). When we consider ISR, the major contribution from the integration over \(x_1\) and \(x_2\) to the cross section is due to the lower limit of the \(s' = x_1 x_2 s \approx m_Z^2\). In this limit the above amplitudes take the forms

\[
|M_a(TR)|^2 \simeq 16[(C_3^L)^2 + (C_3^R)^2]\left(\frac{2}{\sin^2 \theta} - 1\right) \frac{m_Z^2}{(\Delta s)^2}
\]
\[
|M_a(LO)|^2 \simeq 16[(C_3^L)^2 + (C_3^R)^2]\frac{m_Z^2 s}{(s - m_Z^2)^2}
\]

where we use \(s = m_Z^2 + \Delta s\) with \(\Delta s \ll m_Z^2\).

The cross section without ISR leads to \(s' = s\) with \(x_1 = x_2 = 1\). For the collider energy \(\sqrt{s} = 1\) TeV where \(s \gg m_Z^2\) the amplitudes become

\[
|M_a(TR)|^2 \simeq 8[(C_3^L)^2 + (C_3^R)^2]\left(\frac{2}{\sin^2 \theta} - 1\right)(1 + 2 \frac{m_Z^2}{s})
\]
\[
|M_a(LO)|^2 \simeq 16[(C_3^L)^2 + (C_3^R)^2]\frac{m_Z^2 s}{s}
\]

Here the LO cross section continuously decreases as \(s\) increases. This is the expected result for longitudinal polarization. Because there is no LO polarization for massless vector bosons. For \(\sqrt{s} = 10m_Z\) the effect of ISR on both amplitudes can be compared easily as below:

\[
\left|\frac{M_a(TR)}{M_a(LO)}\right|^2_{\text{ISR}} \simeq \frac{2m_Z^4}{(\Delta s)^2}
\]
\[
\left|\frac{M_a(LO)}{M_a(LO)}\right|^2_{\text{ISR}} \simeq 50 \frac{2m_Z^4}{(\Delta s)^2}
\]
FIG. 2: Effect of ISR to the standard model cross section for $e^+e^- \rightarrow \gamma Z$ with transverse and longitudinal polarization of Z boson. Two polarization states, TR and LO, get different contributions from ISR.

Fig. 3 shows the energy dependence of the total cross sections with anomalous coupling parameter $h_{33}^Z = 0.01$ for TR and LO polarization states. The contributions of anomalous couplings become remarkably important after the center of mass energy 500-600 GeV. Effect of ISR is also shown for two cases. In the case of LO polarization, after the energy of 900 GeV the ISR gives negligible corrections. Similar behaviour appears for $h_{33}^Z = 0.01$ and $h_{44}^Z = h_{43}^Z = 0.001$ values. In Fig. 4 the energy dependences of the ISR corrected total cross sections with four anomalous coupling parameters are plotted for LO polarization and unpolarized cases.

It is also important to see how the anomalous couplings change the shape of the angular distribution of the Z boson for the polarized and unpolarized cases. Angular distribution of the Z boson is shown in Fig. 5 for LO polarization state with and without ISR correction. Since the TR polarization state of the Z boson is poorly sensitive to anomalous couplings, angular distributions with TR case are not plotted. In all figures, only one of the coupling parameters are kept different from zero. From all these figures we reach at the following remarkable results. The LO polarization states are always more sensitive to the anomalous couplings. Much larger deviations arise from $h_{44}^V$ for both TR and LO polarizations. $Z\gamma\gamma^*$ couplings always provide the higher contribution to the cross section than the $Z\gamma Z^*$ couplings. The shape of the curves differs for two kinds of polarizations of the Z boson. The ISR correction gives larger contribution to the SM cross section than the case with anomalous couplings. Therefore, the sensitivity of the $e^+e^- \rightarrow \gamma Z$ process to the anomalous couplings is expected to become poorer due to the ISR correction. Numerical results for all polarization configurations will be given in the next section.

IV. LIMITS ON THE ANOMALOUS COUPLING PARAMETERS

If the Z boson decays into a pair of charged leptons the signal for the final states can be $\gamma\ell\ell$ where we consider $\ell = e, \mu$. The potential background processes for $\ell = \mu$ final state are the following:

$e^+e^- \rightarrow Z(\gamma) \rightarrow \gamma\ell\ell : s$ channel Z or $\gamma$ exchange (final state bremsstrahlung).

e$^+e^- \rightarrow \gamma\gamma \rightarrow \gamma\ell\ell : t$ channel $e$ exchange.

For $\ell = e$ final state additional $t$ channel background processes such as those arising from both $Z(\gamma)$ and $e$ exchange; $Z$ or $\gamma$ exchange (final state bremsstrahlung) are present. Since we take into account only on shell Z bosons, we should impose a cut on the invariant mass of charged leptons $M_{\ell\ell} \simeq M_Z$. This cut reduces the effect of background processes...
FIG. 3: Energy dependence of the total cross section for $e^+e^- \rightarrow \gamma Z$ with anomalous $ZZ\gamma$ vertex parameter $h_3^Z = 0.01$. Effects of ISR and Z polarization are also shown. As in the previous figure, two polarization states of the Z boson get different contributions from ISR.

for $\ell = \mu$ drastically. The total cross section of background processes at least 100 times smaller than the process $e^+e^- \rightarrow Z\gamma \rightarrow \gamma\ell\ell$ (t channel e exchange with on shell Z boson). In the case of $\ell = e$ final state background cross sections are 10 times higher when compared to $\mu$ final states. Therefore the major potential background is due to $\ell = e$ final states. In the following sensitivity calculation, background contributions have a negligible effect. As in the previous figure, two polarization states of the Z boson get different contributions from ISR.

FIG. 4: Energy dependence of the total cross section for $e^+e^- \rightarrow \gamma Z$ with LO polarization (left) and unpolarized (right) cases. The values of the anomalous $ZZ\gamma$ and $Z\gamma\gamma$ vertex parameters $h_3^Z = h_3^\gamma = 0.01$ and $h_4^Z = h_4^\gamma = 0.001$ are chosen. All cross sections are ISR corrected.

FIG. 5: Angular distributions of the outgoing $Z$ boson in the center of mass frame of outgoing $Z$ and the photon. $\theta$ is the angle between the outgoing $Z$ boson and the incoming electron. Angular dependence of the four anomalous couplings are shown with (left) and without(right) ISR corrections. Only LO polarization states are taken into account in these figures since TR polarization states are poorly sensitive to anomalous couplings.
TABLE I: Sensitivity of the linear $e^+e^-$ collider to $ZZ\gamma$ and $Z\gamma\gamma$ couplings at 95% C.L. for $\sqrt{s} = 0.5$ TeV and $L_{int} = 500 \text{ fb}^{-1}$. Only one of the couplings is assumed to deviate from the SM at a time.

| $\lambda_2$ | $h_3^Z$ | $h_4^Z$ | $h_5^\gamma$ | $h_6^\gamma$ |
|-------------|---------|---------|-------------|-------------|

State electromagnetic radiative correction improves the number of events especially for the Standard Model processes at the linear collider energies. Furthermore, LO polarization case gets larger contribution from the ISR than the case of TR polarization.

Some limits on the above couplings via $e^+e^- \to ZZ\gamma$ process at linear collider energies from similar works are the following for comparison: the sensitivity (one standard deviation) $2 \times 10^{-4}$, $4 \times 10^{-3}$, $4 \times 10^{-5}$, $3 \times 10^{-4}$ for $h_3^Z$, $h_4^Z$, $h_5^\gamma$, $h_6^\gamma$, respectively at 500 GeV energy and 100 fb$^{-1}$ luminosity [3]; the sensitivity (95% C.L.) $O(10^{-2})$ for $h_3^Z$, $h_4^Z$, $O(10^{-3})$ for $h_5^\gamma$, $h_6^\gamma$ at 500 GeV and 10 fb$^{-1}$ [10]. Predictions from CERN LHC [2] give the limits $5.2 \times 10^{-3}$, $3.7 \times 10^{-5}$ for $h_3^Z$ and $h_4^Z$ at 2$\sigma$, 10 fb$^{-1}$. Comparison of the results in this work at $\sqrt{s} = 1.5$ TeV with those of LHC shows that our results are improved one order of magnitude. For more precise results, further analysis needs to be supplemented with a more detailed knowledge of the experimental conditions.

There are four Feynman diagrams for the process $e^+e^- \rightarrow Z\gamma$ if one includes $Z\gamma Z^*$, $Z\gamma\gamma^*$ vertices. Helicity amplitudes $M_1$ and $M_2$ are responsible for the diagrams concerning $Z\gamma Z^*$ and $Z\gamma\gamma^*$ interactions arising from s channel $Z$ or $\gamma$ exchanges. $M_3$ and $M_4$ are standard model contribution of the $t$ and $u$ channel of the process. The parameters of the helicity amplitudes $M(\sigma_e, \sigma'_e, \lambda_Z, \lambda_\gamma)$ are helicities of incoming electron and positron, outgoing $Z$ boson and photon. The values they take are given by:

$$\sigma_e : L, R \quad, \quad \sigma'_e : L, R \quad, \quad \lambda_Z : +, -, 0 \quad, \quad \lambda_\gamma : +, -$$ (A.1)

Here L and R stand for left and right. Helicity amplitudes we have obtained for each Feynman diagram in the c.m. frame of $e^+e^-$ can be written as follows:

$$M(\sigma_e, \sigma'_e; \lambda_Z, \lambda_\gamma) = M_1(\sigma_e, \sigma'_e; \lambda_Z, \lambda_\gamma) + M_2(\sigma_e, \sigma'_e; \lambda_Z, \lambda_\gamma) + M_3(\sigma_e, \sigma'_e; \lambda_Z, \lambda_\gamma) + M_4(\sigma_e, \sigma'_e; \lambda_Z, \lambda_\gamma)$$ (A.2)

$$M_1(LR; ++) = -C^L h^Z_3 (M_Z^2 - s) \sin \theta$$ (A.3)

$$M_1(LR; ++) = -C^R h^Z_3 (M_Z^2 - s) \sin \theta$$ (A.4)

$$M_1(LR; --) = 0$$ (A.5)

$$M_1(RL; --) = 0$$ (A.6)

$$M_1(LR; -+) = C^L h^Z_3 (M_Z^2 - s) \sin \theta$$ (A.7)

$$M_1(RL; -+) = -C^R h^Z_3 (M_Z^2 - s) \sin \theta$$ (A.8)

$$M_1(LR; +-) = 0$$ (A.9)

$$M_1(RL; +-) = 0$$ (A.10)

$$M_1(LR; 0+) = -\frac{C^L}{\sqrt{2}M_Z} \sqrt{s(M_Z^2 - s)} (1 + \cos \theta) \left[ h^Z_3 + \frac{(M_Z^2 - s)h^2_{2Z}}{2M_Z^2} \right]$$ (A.11)

$$M_1(RL; 0+) = \frac{C^R}{\sqrt{2}M_Z} \sqrt{s(M_Z^2 - s)} (1 - \cos \theta) \left[ h^Z_3 + \frac{(M_Z^2 - s)h^2_{2Z}}{2M_Z^2} \right]$$ (A.12)

$$M_1(LR; 0-) = \frac{C^L}{\sqrt{2}M_Z} \sqrt{s(M_Z^2 - s)} (1 - \cos \theta) \left[ h^Z_3 + \frac{(M_Z^2 - s)h^2_{2Z}}{2M_Z^2} \right]$$ (A.13)

$$M_1(RL; 0-) = -\frac{C^R}{\sqrt{2}M_Z} \sqrt{s(M_Z^2 - s)} (1 + \cos \theta) \left[ h^Z_3 + \frac{(M_Z^2 - s)h^2_{2Z}}{2M_Z^2} \right]$$ (A.14)
