Abstract

We generalize the virial theorem to the warped DGP brane-world scenario and consider its implications on the virial mass. In this theory the four-dimensional scalar curvature term is included in the bulk action and the resulting four-dimensional effective Einstein equation is augmented with extra terms which can be interpreted as geometrical mass, contributing to the gravitational energy. Estimating the geometrical mass \( M(r) \) using the observational data, we show that these geometric terms may account for the virial mass discrepancy in clusters of galaxies. Finally, we obtain the radial velocity dispersion of galaxy clusters \( \sigma_r(r) \) and show that it is compatible with the radial velocity dispersion profile of such clusters.

Key words: Virial theorem, brane-world, relativistic Boltzmann equation, velocity dispersion relation.

1 Introduction

In recent times theories with higher-dimensions have become popular in high energy physics, specially in the context of hierarchy problem and cosmology [1]. In this scenario it is purported that our four-dimensional universe is a subspace called the brane, embedded in a higher-dimensional space-time called the bulk. One of the most successful of such higher-dimensional models is that proposed by Randall and Sundrum whose the bulk has the geometry of an AdS space admitting \( Z_2 \) symmetry [2]. They were successful in explaining what is known as the hierarchy problem: the enormous disparity between the strength of the fundamental forces. The Randall Sundrum (RS) scenario has had a great impact on our undersetting of the universe and has brought higher-dimensional gravitational theories to the fore. In certain RS type models, all matter and gauge interactions reside on the brane while gravity can propagate into the bulk. Using the Israel junction conditions [3] and the Gauss-Codazzi equations, one can obtain the field equations on the brane, as employed by Shiromizu, Maeda and Sasaki (SMS) [4]. There are two very important results that arise from the effective four-dimensional Einstein equations on the brane. The first one is quadratic energy-momentum tensor, \( \pi_{\mu\nu} \), which is relevant in high energy and the second one is the projected Weyl tensor, \( \mathcal{E}_{\mu\nu} \), on the brane which is responsible for carrying on the brane the contribution of the bulk gravitational field. The cosmological evolution of such a brane universe has been extensively investigated and effects such as a quadratic density term in the Friedmann equations have been found [5, 6, 7].

An alternative scenario was subsequently proposed by Dvali, Gabadadze and Porrati (DGP) [8]. The DGP proposal rests on the key assumption of the presence of a four-dimensional Ricci scalar in the bulk action. There are two main reasons that make this model phenomenologically appealing. First, it predicts that four-dimensional Newtonian gravity on a brane-world is regained at distances shorter

†E-mail: m.heydarifard@sbu.ac.ir
‡E-mail: mheydarifard@qom.ac.ir
than a given crossover scale $r_c$ (high energy limit), whereas five-dimensional effects become manifest above that scale (low energy limit) [9]. Second, the model can explain late-time acceleration without having to invoke a cosmological constant or quintessential matter [10]. An extension of the DGP brane-world scenario have been constructed by Maeda, Mizuno and Torii which is the combination of the RS II model and DGP model [11]. In this combination, an induced curvature term appears on the brane in the RS II model. This model has been called the warped DGP brane-world in literature [12]. In this paper, we consider the effective gravitational field equations within the context of the warped DGP brane-world model and obtain the spherically symmetric equations in this scenario. So much for the success of the DGP model, a word of caution is in order; the theory predicts the existence of ghost-like excitations. Many scenarios have been undertaken to explain away such ghosts, but as yet no satisfactory solution exists. The interested reader should consult [13] for further insight. We do not discuss such excitations since our aim lies in studying the virial mass discrepancy in warped DGP models.

Modern astrophysical and cosmological models are faced with two severe theoretical difficulties which can be summarized as dark energy and dark matter problems. The problem of dark matter is a longstanding problem in modern astrophysics. Two important observational issues, the behavior of the galactic rotation curves and the mass discrepancy in clusters of galaxies led to the necessity of considering the existence of dark matter at the galactic and extra-galactic scales [14]. The total mass of a cluster can be estimated in two ways. One can apply the virial theorem to estimate the total dynamic mass $M_V$ of a rich galaxy cluster from measurements of the velocities of the member galaxies and the cluster radius from the volume they occupy. The second is obtained by separately estimating the mass of each individual members and summing them up to give a total baryonic mass $M$. It is always found that $M_V$ is greater than $M$. This is known as the missing mass problem. Nevertheless, the existence of dark matter was not firmly established until time when the measurement of the rotational velocity of stars and gas orbiting at a distance $r$ from the galactic center was performed. Observations show that the rotational velocity increase near the center of galaxy and remain nearly constant. This discrepancy between the observed rotation velocity curves and the theoretical prediction from Newtonian mechanics is known as galactic rotation curves problem (Figure 1). These discrepancies are explained by postulating that every galaxy and cluster of galaxy is embedded in a halo made up of some dark matter [14]. To deal with the question of dark matter, a great number of efforts has been concentrated on various modifications to the Einstein and the Newtonian gravity [15, 16, 17, 18, 19]. Several theoretical models, based on a modification of Newton’s law or of general relativity, have been proposed to explain the behavior of the galactic rotation curves. In the modified Newtonian dynamics (MOND) theory which has been proposed by Milgrom [20], the Poisson equation for the gravitational potential, $\nabla^2 \phi = 4\pi G \rho$, is replaced by an equation of the form $\nabla[\mu(x)(|\nabla \phi|/a_0)] = 4\pi G \rho$, where $a_0$ is a fixed constant and $\mu(x)$ a function satisfying the conditions $\mu(x) = x$ for $x << 1$ and $\mu(x) = 1$ for $x >> 1$. The force law, giving the acceleration $a$ of a test particle becomes $a = a_N$ for $a_N >> a_0$ and $a = \sqrt{a_N a_0}$ for $a_N << a_0$, where $a_N$ is the usual Newtonian acceleration. The rotation curves of the galaxies are predicted to be flat, and they can be calculated once the distribution of the baryonic matter is known. A relativistic MOND inspired theory was developed by Bekenstein [21]. In this theory gravitation is mediated by a metric, a scalar field and a four-vector field, all three dynamical. For alternative theoretical models to explain the galactic rotation curves, see [22]. One other such modification is that of the RS brane-world scenario [23]. It has been argued that a modified theory of gravity based on the RS brane-world scenario can explain the observations of the galactic rotation curve of spiral galaxies and the virial theorem mass discrepancy in clusters of galaxies without introducing any additional hypothesis [23].

Our main purpose in this paper is to obtain the generalized form of the virial theorem in Warped DGP brane-world model by using the collision-less Boltzmann equation. In what follows, we first give a brief review of warped DGP brane-world model and the gravitational field equations are derived in this model. Next, we use the relativistic Boltzmann equation to derive the virial theorem which
Figure 1: Observed rotation velocity curve of the NGC3198 (dotted line) and the prediction from Newtonian theory (solid line).

is modified by an extra term which may be used to explain the virial mass discrepancy in clusters of galaxies. Finally, we identify the geometrical mass of cluster in terms of the observable quantities and obtain the radial velocity dispersion of galaxy clusters.

2 Effective field equations on warped DGP brane

Let us start by presenting the model used in our calculation [11]. Consider a five-dimensional space-time with a four-dimensional brane is located at $Y(X^A) = 0$, where $X^A$, $(A = 0, 1, 2, 3, 4)$ are five-dimensional coordinates. The effective action is given by

$$S = S_{\text{bulk}} + S_{\text{brane}}, \quad (1)$$

where

$$S_{\text{bulk}} = \int d^5X \sqrt{-G} \left[ \frac{1}{2\kappa_5^2} R + L_m^{(5)} \right], \quad (2)$$

and

$$S_{\text{brane}} = \int_{Y=0} d^4x \sqrt{-g} \left[ \frac{1}{\kappa_5^2} K^\pm + L_{\text{brane}}(g_{\alpha\beta}, \psi) \right], \quad (3)$$

where $\kappa_5^2 = 8\pi G_5$ is the five-dimensional gravitational constant, $R$ and $L_m^{(5)}$ are the five-dimensional scalar curvature and the matter Lagrangian in the bulk, respectively. Also, $x^\mu$, $(\mu = 0, 1, 2, 3)$ are the induced four-dimensional coordinates on the brane, $K^\pm$ is the trace of extrinsic curvature on either side of the brane [24, 25] and $L_{\text{brane}}(g_{\alpha\beta}, \psi)$ is the effective four-dimensional Lagrangian, which is given by a generic functional of the brane metric $g_{\alpha\beta}$ and matter fields.

The five-dimensional Einstein field equations are given by

$$R_{AB} - \frac{1}{2} R g_{AB} = \kappa_5^2 \left[ T_{AB}^{(5)} + \delta(Y)\tau_{AB} \right], \quad (4)$$

where

$$T_{AB}^{(5)} \equiv -2 \frac{\delta L_m^{(5)}}{\delta g_{AB}} + g_{AB} L_m^{(5)}, \quad (5)$$

and

$$\tau_{\mu\nu} \equiv -2 \frac{\delta L_{\text{brane}}}{\delta g^{\mu\nu}} + g_{\mu\nu} L_{\text{brane}}. \quad (6)$$

We study the case with an induced gravity on the brane due to quantum corrections [8]. The interaction between bulk gravity and the matter on the brane induces gravity on the brane through
its quantum effects. If we take into account quantum effects of matter fields confined on the brane, the gravitational action on the brane is modified as

$$\mathcal{L}_{\text{brane}}(g_{\alpha\beta}, \psi) = \frac{\mu^2}{2} R - \lambda_b + \mathcal{L}_m,$$  \hspace{1cm} (7)

where $\mu$ is a mass scale which may correspond to the four-dimensional Planck mass, $\lambda_b$ is the tension of the brane and $\mathcal{L}_m$ presents the Lagrangian of the matter fields on the brane. We note that for $\lambda_b = 0$ and $\Lambda^{(5)} = 0$ action (1) gives the DGP model and gives the RS II model if $\mu = 0$.

We obtain the gravitational field equations on the brane-world as [4]

$$G_{\mu\nu} = \frac{2\kappa_5^2}{3} \left[ T^{(5)}_{AB} g^A_{\mu} g^B_{\nu} + g_{\mu\nu} \left( T^{(5)}_{AB} n^A n^B - \frac{1}{4} T^{(5)} \right) \right] + \kappa_5^2 \pi_{\mu\nu} - \mathcal{E}_{\mu\nu},$$  \hspace{1cm} (8)

where $\pi_{\mu\nu}$ is the energy-momentum tensor of the brane

$$\pi_{\mu\nu} = - \frac{1}{4} \tau_{\mu\nu} \tau^\alpha \tau^\alpha + \frac{1}{12} \tau_{\mu\nu} + \frac{1}{8} g_{\mu\nu} \tau^\alpha \tau_{\alpha\beta} - \frac{1}{24} g_{\mu\nu} \tau^2,$$  \hspace{1cm} (10)

and the projection of the bulk Weyl tensor to the surface orthogonal to $n^A$ is given by

$$\mathcal{E}_{\mu\nu} = C^{(5)}_{ABCD} n^A g^B g^C g^D.$$  \hspace{1cm} (11)

The symmetry properties of $\mathcal{E}_{\mu\nu}$ imply that in general we can decompose it irredudcibly with respect to a chosen 4-velocity field $v^\mu$ as [6]

$$\mathcal{E}_{\mu\nu} = - \left( \frac{\kappa_5}{\kappa_4} \right)^4 \left[ U(v_\mu v_\nu + \frac{1}{3} h_{\mu\nu}) + 2Q(\mu v_\nu) + P_{\mu\nu} \right],$$  \hspace{1cm} (12)

where $h_{\mu\nu} = g_{\mu\nu} + v_\mu v_\nu$ projects orthogonal to $v_\mu$ and the factor $(\kappa_5/\kappa_4)$ is introduced for dimension reasons. Here

$$U = - \left( \frac{\kappa_4}{\kappa_5} \right)^4 \mathcal{E}_{\mu\nu} v^\mu v^\nu,$$

is an effective non-local energy density or “dark radiation” term on the brane, arising from the free gravitational field in the bulk, $Q_\mu = (\kappa_4/\kappa_5)^4 h_\mu^\alpha \mathcal{E}_{\alpha\beta} v^\beta$ is an effective non-local energy flux and

$$P_{\mu\nu} = - \left( \frac{\kappa_4}{\kappa_5} \right)^4 \left[ h_\mu^\alpha h_\nu^\beta - \frac{1}{3} h_{\mu\nu} h^{\alpha\beta} \right] \mathcal{E}_{\alpha\beta},$$

is a spatial, symmetric and trace-free tensor. In what follows for the static spherically symmetric brane we have $Q_\mu = 0$, and we may choose $P_{\mu\nu} = P(r)(r_\mu r_\nu - \frac{1}{3} h_{\mu\nu})$, where the “dark pressure” $P(r)$ is a scalar functions of the radial distance $r$, $r_\mu$ is a unit radial vector and at any point on the brane in inertial frame $v^\mu = \delta^\mu_0$, $h_{\mu\nu} = \text{diag}(0,1,1,1)$ [26].

In order to find the basic field equations on the brane with induced gravity, we have to obtain the energy-momentum tensor of the brane $\tau_{\mu\nu}$, given by definition (6) from the Lagrangian (7), yielding

$$\tau^{\mu\nu} = -\lambda_b \delta^{\mu\nu} + T^{\mu\nu} - \mu^2 G^{\mu\nu},$$  \hspace{1cm} (13)

Assuming that the five-dimensional bulk space includes only a cosmological constant $\Lambda^{(5)}$ and inserting equation (13) into equation (8), we find the effective field equations for four-dimensional metric $g_{\mu\nu}$ as

$$\left( 1 + \frac{\lambda_b}{6} \kappa_5^2 \mu^2 \right) G_{\mu\nu} = \frac{1}{6} \lambda_b \kappa_5^4 T_{\mu\nu} - \Lambda_4 g_{\mu\nu} - \kappa_5^4 \mu^2 K_{\mu\nu\alpha\beta} G^{\alpha\beta} + \kappa_5^4 \left[ \tau^{(T)}_{\mu\nu} + \mu^4 \tau^{(G)}_{\mu\nu} \right] - \mathcal{E}_{\mu\nu},$$  \hspace{1cm} (14)
where
\[ K_{\mu \nu \rho \sigma} = \frac{1}{4} (g_{\mu \nu} T_{\rho \sigma} - g_{\mu \rho} T_{\nu \sigma} - g_{\nu \sigma} T_{\mu \rho} + \frac{1}{12} [T_{\mu \nu} g_{\rho \sigma} + T(g_{\mu \rho} g_{\nu \sigma} - g_{\mu \sigma} g_{\nu \rho})]), \tag{15} \]
\[ \pi^{(T)}_{\mu \nu} = -\frac{1}{4} T_{\mu \alpha} T_{\nu}^{\alpha} + \frac{1}{12} T T_{\mu \nu} + \frac{1}{8} g_{\mu \nu} T_{\alpha \beta} T^{\alpha \beta} - \frac{1}{24} g_{\mu \nu} T^2, \tag{16} \]
\[ \pi^{(G)}_{\mu \nu} = -\frac{1}{4} G_{\mu \alpha} G_{\nu}^{\alpha} + \frac{1}{12} G G_{\mu \nu} + \frac{1}{8} g_{\mu \nu} G_{\alpha \beta} G^{\alpha \beta} - \frac{1}{24} g_{\mu \nu} G^2, \tag{17} \]
and the effective cosmological constant on the brane is given by
\[ \Lambda_4 = \frac{\kappa_5^2}{2} \left[ \Lambda^{(5)} + \frac{1}{6} \kappa_5^2 \lambda_6^0 \right]. \tag{18} \]
We note that for \( \mu = 0 \) these equations are exactly the same effective equations as in the reference [4].

3 Field equations for a cluster including identical and collision-less point particles

Now we consider an isolated and spherically symmetric cluster being described by a static and spherically symmetric metric
\[ ds^2 = -e^{\lambda(r)} dt^2 + e^{\nu(r)} dr^2 + r^2 (d\theta^2 + \sin^2 \theta d\phi^2). \tag{19} \]
Suppose that the clusters are constructed from identical and collision-less point particles (galaxies). This multi-particle system can be described by a continuous non-negative function \( f_B(x^\mu, p^\mu) \), distribution function, which is defined over the phase space. In terms of the distribution function the energy-momentum tensor can be written as [27, 28]
\[ T_{\mu \nu} = \int f_B m v_\mu v_\nu dv, \tag{20} \]
where \( m \) is the mass of each galaxy, \( v_\mu \) is the four-velocity of the galaxy and \( dv = \frac{1}{v_t} dv_t dv_\theta dv_\phi \) is the invariant volume element of the velocity space. We also assume that the matter content of the bulk is just a cosmological constant \( \Lambda^{(5)} \) and the energy-momentum tensor of the matter in a cluster of galaxies can be represented in terms of spherically symmetric perfect fluid as
\[ T_{\mu \nu} = (\rho_b + \rho_0) v_\mu v_\nu + p_b g_{\mu \nu}, \tag{21} \]
where \( v_\mu v^\mu = -1 \). Use of equations (20) and (21) leads to the following relation for \( \rho_b \) and \( p_b \)
\[ \rho_b = \rho \langle v_t^2 \rangle, \quad p_b = \rho \langle v_\theta^2 \rangle = \rho \langle v_\phi^2 \rangle, \tag{22} \]
here \( \langle v_t^2 \rangle \) represents the usual macroscopic averaging which is defined as \( \langle v_t^2 \rangle = \frac{1}{f} \int f_B v_t^2 mdv \) where \( \rho \) is the mass density and in term of \( f_B \) is given by \( \rho = \int f_B mdv \) [29, 30].

Using equation (14), the gravitational field equations on the brane become
\[ (1 + \frac{\lambda_b}{6} \kappa_5^4 \mu^2) \frac{e^{-\nu}}{r^2} \left(-1 + r \nu' + e^\nu \right) = \frac{1}{6} \lambda_b \kappa_5^4 \rho_b + \Lambda_4 + \kappa_5^4 \mu^2 \kappa_0^0 + \frac{\kappa_4^4}{12} \rho_b^2 - \kappa_5^4 \mu^2 \pi_0^0 + \frac{6}{\kappa_4^4 \lambda_b} U(r), \tag{23} \]
\[ (1 + \frac{\lambda_b}{6} \kappa_5^4 \mu^2) \frac{e^{-\nu}}{r^2} \left(1 + r \lambda' - e^{-\nu} \right) = \frac{1}{6} \lambda_b \kappa_5^4 \rho_b - \Lambda_4 + \kappa_5^4 \mu^2 \kappa_1^1 + \frac{\kappa_4^4}{12} \left( \rho_b^2 + 2 \rho_0 \rho_b \right) + \kappa_5^4 \mu^4 \pi_1^1, \tag{24} \]
\[ (1 + \frac{\lambda_0 \kappa_5^4 \mu_2^2}{6r}) e^{-\nu} \left( 2\lambda' - 2\nu' - \lambda'' r + 2\lambda'' + \lambda^2 r \right) = \frac{1}{3} \lambda_0 \kappa_5^4 \mu_2 \rho_b - 2\lambda_0 - 2\kappa_5^4 \mu_2 K_2^2 + \frac{\kappa_5^4}{6} \left( \rho_b^2 + 2\rho_b \rho_b \right) + 2\kappa_5^4 \mu_2^2 \pi_2^{(G)} + \frac{4}{\kappa_5^4 \lambda_0} [U(r) - P(r)], \]

where \( U(r) \) and \( P(r) \) are the dark radiation and dark pressure and \( K_{\mu \nu \alpha \beta} G^{\alpha \beta} \equiv K_{\mu \nu} \) term is given by

\[
K_0^0 = \frac{e^{-\nu} \left[ (p_b + p_b) - 4p_b \frac{\lambda'}{r^2} - \frac{2}{r} (p_b + p_b) \right] + 2p_b e^{-\nu} \left[ \frac{4\nu' - 2\nu'}{r^2} + \frac{2\nu}{r} + 4\lambda' \nu' - 2\lambda'' - \lambda^2 \right] + \left[ \frac{2\nu}{r} + \frac{4\nu'}{r} + \frac{4\lambda' \nu' - 2\lambda'' - \lambda^2}{r^2} \right], \]

\[
K_1^1 = \frac{e^{-\nu} \left[ (p_b - 3p_b) \right] + 2p_b e^{-\nu} \left[ \frac{4\nu'}{r^2} - \frac{4\nu'}{r} \right] + \frac{2}{r} (p_b + p_b) \left[ \frac{4\nu'}{r^2} + \frac{4\nu'}{r} \right] + \left[ \frac{4\nu'}{r} + \frac{4\nu'}{r^2} - \frac{4\lambda' \nu' - 2\lambda'' - \lambda^2}{r^2} \right], \]

\[
K_2^2 = \frac{e^{-\nu} \left[ (p_b - 3p_b) \right] + 2p_b e^{-\nu} \left[ \frac{4\nu'}{r^2} - \frac{4\nu'}{r} \right] + \frac{2}{r} (p_b + p_b) \left[ \frac{4\nu'}{r^2} + \frac{4\nu'}{r} \right] + \left[ \frac{4\nu'}{r} + \frac{4\nu'}{r^2} - \frac{4\lambda' \nu' - 2\lambda'' - \lambda^2}{r^2} \right], \]

and use of equation (17) leads to the components of \( \pi_0^{(G)} \) as

\[
\pi_0^{(G)} = \frac{e^{-\nu}}{24} \left[ \frac{-6\nu'}{r^3} + \frac{2\lambda'}{r^2} - \frac{2\lambda'' + \lambda^2}{r^2} \right] + \frac{e^{-2\nu} \left[ 16\lambda' \right]}{192 \left[ r^3 - \frac{8}{r} \lambda' \nu' + 16\lambda'' \right] - \frac{16\lambda'}{r^2} + \frac{4\lambda'' + \lambda^2}{r^2} \right] + \frac{e^{-2\nu} \left[ 16\lambda' \right]}{192 \left[ r^3 - \frac{8}{r} \lambda' \nu' + 16\lambda'' \right] - \frac{16\lambda'}{r^2} + \frac{4\lambda'' + \lambda^2}{r^2} \right], \]

\[
\pi_1^{(G)} = \frac{e^{-\nu}}{24} \left[ \frac{2\nu'}{r^3} + \frac{6\lambda'}{r^3} - \frac{2\lambda''}{r^2} + \frac{2\lambda'' + \lambda^2}{r^2} \right] + \frac{e^{-2\nu} \left[ 16\lambda' \right]}{192 \left[ r^3 - \frac{8}{r} \lambda' \nu' + 16\lambda'' \right] - \frac{16\lambda'}{r^2} + \frac{4\lambda'' + \lambda^2}{r^2} \right] + \frac{e^{-2\nu} \left[ 16\lambda' \right]}{192 \left[ r^3 - \frac{8}{r} \lambda' \nu' + 16\lambda'' \right] - \frac{16\lambda'}{r^2} + \frac{4\lambda'' + \lambda^2}{r^2} \right], \]

\[
\pi_2^{(G)} = \frac{e^{-\nu}}{24} \left[ \frac{4\lambda'}{r^4} - \frac{2\lambda''}{r^2} - \frac{2\lambda'' + \lambda^2}{r^2} \right] + \frac{e^{-2\nu} \left[ 16\lambda' \right]}{192 \left[ r^3 - \frac{8}{r} \lambda' \nu' + 16\lambda'' \right] - \frac{16\lambda'}{r^2} + \frac{4\lambda'' + \lambda^2}{r^2} \right] + \frac{e^{-2\nu} \left[ 16\lambda' \right]}{192 \left[ r^3 - \frac{8}{r} \lambda' \nu' + 16\lambda'' \right] - \frac{16\lambda'}{r^2} + \frac{4\lambda'' + \lambda^2}{r^2} \right], \]

where a prime represents differentiation with respect to \( r \). In the next section, we will investigate the influence of the bulk effects on the dynamics of the galaxies in warped DGP brane-world model.
4 The virial theorem in warped DGP brane

In order to derive the virial theorem for galaxy clusters, we have to first write down the general relativistic Boltzmann equation governing the evolution of the distribution function \( f_B \). The galaxies, which are treated as identical and collision-less point particles, are described by this distribution function. For the static spherically symmetric metric given by equation (19) we introduce the following frame of orthonormal vectors \([27, 28, 29]\)

\[
e^0_\rho = e^{\lambda/2} \delta^0_\rho, \quad e^1_\rho = e^{\nu/2} \delta^1_\rho, \quad e^2_\rho = r \delta^2_\rho, \quad e^3_\rho = r \sin \theta \delta^3_\rho, \tag{32}
\]

where \( g^{\mu\nu} e^a_\mu e^b_\nu = \eta^{(a)(b)} \). The four-velocity \( v^\mu \) of a typical galaxy with \( v^\mu v_\mu = -1 \), in tetrad components is written as

\[
v^{(a)} = v^\mu e^a_\mu, \quad a = 0, 1, 2, 3. \tag{33}
\]

The relativistic Boltzmann equation in tetrad components is given by

\[
v^{(a)} e^\rho_\mu \frac{\partial f_B}{\partial x^\rho} + \gamma^{(a)}_{(b)(c)} v^{(b)} v^{(c)} \frac{\partial f_B}{\partial v^{(a)}} = 0, \tag{34}
\]

where \( f_B = f_B(x^\mu, v^{(a)}) \) and \( \gamma^{(a)}_{(b)(c)} = e^{(a)}_\mu e^{(b)}_\nu e^{(c)}_\sigma \) are the distribution function and the Ricci rotation coefficients, respectively. Assuming that the distribution function is only a function of \( r \), the relativistic Boltzmann equation becomes

\[
v_r \frac{\partial f_B}{\partial r} - \left[ \frac{v^2_r}{2} \frac{\partial \lambda}{\partial r} - \frac{(v^2_\theta + v^2_\varphi)}{r} \right] \frac{\partial f_B}{\partial v_r} - \frac{v_r}{r} \left[ v_\theta \frac{\partial f_B}{\partial v_\theta} + v_\varphi \frac{\partial f_B}{\partial v_\varphi} \right] - \frac{e^{\nu/2} v_\varphi}{r} \cot \theta \left[ v_\theta \frac{\partial f_B}{\partial v_\varphi} - v_\varphi \frac{\partial f_B}{\partial v_\theta} \right] = 0, \tag{35}
\]

where we have defined

\[
v^{(0)} = v_t, \quad v^{(1)} = v_r, \quad v^{(2)} = v_\theta, \quad v^{(3)} = v_\varphi. \tag{36}
\]

Since we have assumed the system to be spherically symmetric, the term proportional to \( \cot \theta \) must be zero. Multiplying equation (35) by \( m v_r dv \) where \( dv = \frac{1}{v^2_\varphi} dv_\varphi dv_\theta dv_r \), and integrating over the velocity space and assuming that the distribution function vanishes rapidly as the velocities tend to \( \pm \infty \), we obtain

\[
\rho \frac{\partial}{\partial r} \left[ \rho \langle v^2_r \rangle \right] + \frac{1}{2} \rho \left[ \langle v^2_\theta \rangle + \langle v^2_\varphi \rangle \right] r \frac{\partial \lambda}{\partial r} - \rho \left[ \langle v^2_\theta \rangle + \langle v^2_\varphi \rangle - 2 \langle v^2_r \rangle \right] = 0, \tag{37}
\]

where \( \rho \) is the mass density and \( \langle v^2_r \rangle \) represents the average value of \( v^2_r \). Multiplying equation (37) by \( 4 \pi r^2 \) and integrating over the cluster leads to

\[
\int_0^R 4 \pi \rho \left[ \langle v^2_r \rangle + \langle v^2_\theta \rangle + \langle v^2_\varphi \rangle \right] r^2 dr - \frac{1}{2} \int_0^R 4 \pi r^3 \rho \left[ \langle v^2_\theta \rangle + \langle v^2_\varphi \rangle \right] \frac{\partial \lambda}{\partial r} dr = 0. \tag{38}
\]

This equation is reduced to

\[
2 K - \frac{1}{2} \int_0^R 4 \pi r^3 \rho \left[ \langle v^2_\theta \rangle + \langle v^2_\varphi \rangle \right] \frac{\partial \lambda}{\partial r} dr = 0, \tag{39}
\]

where the total kinetic energy of the galaxies is defined as

\[
K = \int_0^R 2 \pi \rho \left[ \langle v^2_\theta \rangle + \langle v^2_\varphi \rangle \right] r^2 dr. \tag{40}
\]

Now, using these relations and adding the gravitational field equations (23)-(25) and equation (22) we find
\[
\left(1 + \frac{\lambda_b \kappa_4^4 \mu^2}{6} \right) e^{-\nu} \left( \frac{\lambda'}{r} - \frac{\lambda''}{2} + \frac{\lambda'^2}{4} \right) = \frac{\kappa_4^2}{2} \rho \left[ \langle v_r^2 \rangle + \langle v_\theta^2 \rangle + \langle v_\varphi^2 \rangle \right] + \frac{\kappa_4^4 \mu^2}{2} \rho^2 \left[ \langle v_r^2 \rangle + \langle v_\theta^2 \rangle + \langle v_\varphi^2 \rangle \right] \]
\[
\quad + \frac{\kappa_4^2}{2 \lambda_b} \rho^2 \left[ \langle v_r^2 \rangle + \langle v_\theta^2 \rangle + \langle v_\varphi^2 \rangle \right] - \Lambda_4 - \frac{\kappa_4^4 \mu^2}{6r} \rho \left[ 3\nu'\langle v_r^2 \rangle + 2\lambda'\langle v_r^2 \rangle + \lambda'' r\langle v_r^2 \rangle + 3\nu'\langle v_r^2 \rangle \right] + \frac{6}{\kappa_4 \lambda_b} U(r). \tag{41}
\]

where \( \frac{1}{6} \lambda_b \kappa_4^4 = \kappa_4^2 \). In order to obtain the generalized virial theorem we have to use some approximations. First, since the dispersion of the velocity of galaxies in the clusters is of the order \( 600 - 1000 \text{ km/s} \), i.e., \( \langle v^2 \rangle \approx 4 \times 10^{-6} - 1.11 \times 10^{-5} \ll 1 \), we can neglect the relativistic effects in the relativistic Boltzmann equation and use the small velocity limit approximation. In other words, \( \langle v_2 \rangle \approx \langle v_3 \rangle \approx \langle v_4 \rangle \approx 1 \). Second, the intensity of the gravitational effects can be estimated from the ratio \( GM/R \), which for typical clusters is of the order of \( 10^{-6} \ll 1 \). Therefore inside the galactic clusters the gravitational field is weak and we can use the weak gravitational field approximation. Then the term proportional to \( \lambda' \) and \( \lambda^2 \) in equation (41) may be ignored. Thus, assuming that \( e^\lambda \approx e^\nu \approx 1 \) inside the cluster \([23]\), we can write equations (41) as

\[
\left(1 + \frac{\lambda_b \kappa_4^4 \mu^2}{6} \right) \frac{1}{2r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial \lambda}{\partial r} \right) = \frac{\kappa_4^2}{2} \rho - \Lambda_4 + \frac{\kappa_4^4 \mu^2}{2} \left[ \langle v_r^2 \rangle + \langle v_\theta^2 \rangle + \langle v_\varphi^2 \rangle \right] \]
\[
- \Lambda_4 - \frac{\kappa_4^4 \mu^2}{6r} \rho \left[ 3\nu'\langle v_r^2 \rangle + 2\lambda'\langle v_r^2 \rangle + \lambda'' r\langle v_r^2 \rangle + 3\nu'\langle v_r^2 \rangle \right] + \frac{6}{\kappa_4 \lambda_b} U(r). \tag{42}
\]

On the other hand, for clusters of galaxies the ratio of the matter density and of the brane tension is much smaller than 1, \( \rho/\lambda_b \ll 1 \), so that one can neglect the quadratic term in the matter density in above equation. These conditions certainly apply to test particles in stable circular motion around galaxies, and to the galactic clusters. Thus, we can rewrite equation (42) as

\[
\left(1 + \frac{\lambda_b \kappa_4^4 \mu^2}{6} \right) \frac{1}{2r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial \lambda}{\partial r} \right) = \frac{\kappa_4^2}{2} \rho - \Lambda_4 + \frac{\kappa_4^4 \mu^2}{2} [P(r) + 3U(r)] + \frac{6}{\kappa_4 \lambda_b} U(r), \tag{43}
\]

where

\[
U(r) = \frac{\rho \nu'}{6r},
\]
\[
P(r) = -\frac{\rho \nu'}{6r} \left( r^2 \frac{\partial \lambda}{\partial r} \right).
\]

Multiplying equation (43) by \( r^2 \) and integrating from 0 to \( r \) yields

\[
\left(1 + \frac{\lambda_b \kappa_4^4 \mu^2}{6} \right) \frac{1}{2} \int_0^r \rho(r') r'^2 dr' - \frac{\kappa_4^2}{8\pi} M(r) + \frac{1}{3} \Lambda_4 r^3 - \frac{\kappa_4^2}{8\pi} M_{DGP}(r) - \frac{\kappa_4^2}{8\pi} M_{RS}(r) = 0. \tag{44}
\]

The total baryonic mass and the geometrical masses of the system are given by

\[
M(r) = 4\pi \int_0^r \rho(r') r'^2 dr', \tag{45}
\]

and

\[
\kappa_4^2 M_{RS}(r) = \frac{48\pi}{\kappa_4 \lambda_b} \int_0^r U(r') r'^2 dr', \tag{46}
\]

\[
\kappa_4^2 M_{DGP}(r) = 8\pi \kappa_4^4 \mu^2 \int_0^r [P(r') + 3U(r')] r'^2 dr', \tag{47}
\]
where
\[ M(r) = M_{RS}(r) + M_{DGP}(r). \] (48)

Multiplying equation (44) by \( \frac{dM(r)}{r} \) and integrating from 0 to \( R \), we finally obtain the generalized virial theorem in warped DGP scenario as
\[ \left( 1 + \frac{\lambda_b^4 \kappa^2 \mu^2}{6} \right) 2K + W + \frac{1}{3} \Lambda_4 I + W = 0, \] (49)

where
\[ W = \frac{\kappa_4^2}{8\pi} \int_0^R \frac{M(r)}{r} dM(r), \] (50)
\[ W = -\frac{\kappa_4^2}{2} \int_0^R M(r) \rho r dr, \] (51)
and
\[ I = \int_0^R r^2 dM(r), \] (52)

where \( W \) is the gravitational potential energy of the system. At this point it is worth nothing that for \( \mu = 0 \), we have \( M_{DGP} = 0 \) and the virial theorem in the warped DGP brane-world is reduced to the virial theorem in the RS brane scenario [23]
\[ 2K + W + \frac{1}{3} \Lambda_4 I + W_{RS} = 0, \] (53)
where
\[ W_{RS} = -\frac{\kappa_4^2}{2} \int_0^R M_{RS}(r) \rho r dr. \] (54)

As one can see the gravitational energy modified by \( W_{RS} \) which has its origin in the global bulk effect due to the \( E_{\mu\nu} \) term. We can also recover the virial theorem in the standard general relativity from equation (53) in the limit \( \lambda_b^{-1} \rightarrow 0 \). A alternative possibility in recovering the four-dimensional virial theorem is to take the limit \( \kappa_5 \rightarrow 0 \), while keeping the Newtonian gravitational constant \( \kappa_4^2 \) finite [11].

In the case \( \lambda_b = \Lambda^{(5)} = 0 \), the virial theorem in warped DGP brane-world is reduced to the virial theorem in DGP brane scenario [19]
\[ 2K + W + W_{DGP} = 0, \] (55)
where
\[ W_{DGP} = -\frac{\kappa_4^2}{2} \int_0^R M_{DGP}(r) \rho r dr. \] (56)

Note for a Minkowski DGP bulk space we have \( E_{\mu\nu} = 0 \), thus in above equation \( W_{RS} = 0 \). There is difference between our model with references [23] and [19]. The virial theorem in warped DGP brane-world modified by both \( W_{RS} \) and \( W_{DGP} \), which the first is due to the global bulk effect whereas the second term has its origins in the induced gravity on the brane due to quantum correction.

Now, we introduce the radii \( R_V \), \( R_I \) and \( R \) as
\[ R_V = \frac{M^2(r)}{\int_0^R \frac{M(r)}{r} dM(r)}, \] (57)
where $R_V$ is the virial radius and $\mathcal{R}$ is defined as the geometrical radius of the clusters of galaxies. Defining the virial mass as

\[ 2K = -\frac{\kappa_4^2 M^2}{8\pi R_V}, \tag{60} \]

and using the following relations

\[ W = \frac{\kappa_4^2 M^2}{8\pi R_V}, \quad I = MR_I^2, \tag{61} \]

the generalized virial theorem (49) is simplified as

\[ \left(1 + \frac{\lambda_5}{6\kappa_4^4\mu^2}\right) \left(\frac{M_V}{M}\right)^2 = 1 - \frac{8\pi \Lambda A}{3\kappa_4^2} \frac{R_V R_I^2}{M} + \left(\frac{M}{M}\right)^2 \left(\frac{R_V}{R}\right). \tag{62} \]

We have three types of mass in equation (62), namely, the total baryonic mass of the system represented by $M$ (including the baryonic mass of the intra-cluster gas and of the stars, other particles like massive neutrinos), the virial mass represented by $M_V$ and finally, the geometrical mass represented by $\mathcal{M}$.

On large distance scales associated with galaxies, we can ignore the contribution of the effective cosmological constant to the mass energy of the galaxy. Also, it is found that $M_V$ is considerably greater than $M$ for most of the clusters and we can neglect the term unitary in equation (62). Therefore, the virial mass is given by

\[ M_V(r) \simeq \mathcal{M}(r) \left(\frac{R_V}{R}\right)^{1/2}. \tag{63} \]

This equation shows that the virial mass is proportional to the geometrical mass.

5 Astrophysical applications

In this section, we emphasize that the astrophysical observations together with the cosmological simulations have shown that the virialized part of cluster is a measure of a fixed density such as a critical density, $\rho_c(z)$ at a special red-shift, so that $\rho_V = 3M_V/4\pi R_V^3 = \delta \rho_c(z)$, where $M_V$ and $R_V$ are the virial mass and radius, respectively. As is well known, $\rho_c(z) = h^2(z)3H_0^2/8\pi G$, where the Hubble parameter is normalized to its local value, i.e., $h^2(z) = \Omega_m(1 + z)^3 + \Omega_\Lambda$, where $\Omega_m$ and $\Omega_\Lambda$ are the mass density and dark energy density parameters, respectively [31]. By knowing the integrated mass of the galaxy cluster as a function of the radius, one can estimate the appropriate physical radius for the mass measurement. The radii commonly used are $r_{200}$ or $r_{500}$. These radii lie within the radii corresponding to the mean gravitational mass density of the matter $\rho_{\text{tot}} = 200\rho_c$ or $500\rho_c$. A useful radius is $r_{200}$ to find the virial mass. The numerical values of the radius $r_{200}$ for the cluster NGC 4636 are in the ranges $r_{200} = 0.85 \text{ Mpc}$ and $r_{200} = 4.49 \text{ Mpc}$ for the cluster A2163, so one can deduce that a typical value for $r_{200}$ is $2 \text{ Mpc}$. The masses corresponding to $r_{200}$ and $r_{500}$ are denoted by $M_{200}$ and $M_{500}$, respectively, and it is usually assumed that $M_V = M_{200}$ and $R_V = r_{200}$ [32].
5.1 Geometrical mass estimated using the Jean’s relation

Now, we are going to obtain $M(r)$ as a function of $r$ by comparing the virial theorem results with the observational data for galaxy cluster which can be obtained from the X-ray observation of the gas in the cluster. The most of the baryonic mass in clusters is in the gas form, therefore we assume that the energy-density and pressure in $T_{\mu\nu}$ is that of a gas as

$$
\rho = \rho_g(r), \quad p = p_g(r).
$$

(64)

In majority of clusters most of the baryonic mass is in the form of the intra-cluster gas. The gas mass density $\rho_g(r)$ distribution can be fitted with the observational data by using the following expression for the radial baryonic mass distribution [32]

$$
\rho_g(r) = \rho_0 \left( 1 + \frac{r^2}{r_c^2} \right)^{-\frac{3\beta}{2}},
$$

(65)

where $r_c$ is the core radius, and $\rho_0$ and $\beta$ are cluster independent constants. A static spherically symmetric system of collision-less particles that is in equilibrium, can be described by the Jean’s equation [14]

$$
\frac{d}{dr} \left[ \rho_g(r) \sigma_r^2 + \frac{2 \rho_g(r)}{r} \left( \sigma_r^2 - \sigma_{\theta,\varphi}^2 \right) \right] = -\rho_g(r) \frac{d\Phi(r)}{dr},
$$

(66)

where $\Phi(r)$ is the gravitational potential, $\sigma_r$ and $\sigma_{\theta,\varphi}$ are the mass-weighted velocity dispersions in the radial and tangential directions. We assume that the gas is isotropically distributed inside the cluster, so $\sigma_r = \sigma_{\theta,\varphi}$. The gas pressure is related to the velocity dispersion and gas profile density by $p_g = \rho_g \sigma_r^2$. By assumption that the gravitational field is weak so that it satisfies the usual Poisson equation $2\nabla^2 \Phi \approx \kappa^2 \rho_{tot}$, where $\rho_{tot}$ is the energy density including $\rho_g$ and other forms of matter, like luminous matter and the geometrical matter, etc., the Jean’s equation becomes

$$
\frac{dp_g(r)}{dr} = -\rho_g(r) \frac{d\Phi(r)}{dr} = -\frac{\kappa^2 M_{tot}(r)}{8\pi r^2 \rho_g(r)},
$$

(67)

where $M_{tot}(r)$ is the total mass inside the radius $r$. The observed X-ray emission from the hot ionized intra-cluster gas is usually interpreted by assuming that the gas is in isothermal equilibrium. Therefore we assume that the gas is in equilibrium state having the equation of state $p_g(r) = \frac{k_B T_g}{\mu m_p} \rho_g(r)$, where $k_B$ is Boltzmann constant, $T_g$ is the gas temperature, $\mu = 0.61$ is the mean atomic weight of the particles in the gas cluster and $m_p$ is the proton mass. Equation (67) then gives

$$
M_{tot}(r) = \frac{8\pi k_B T_g r^2}{\mu m_p \kappa^2} \frac{d}{dr} \ln \rho_g(r).
$$

(68)

Now, use of the density profile of the gas given by equation (65) leads to the mass profile inside the cluster as

$$
M_{tot}(r) = \frac{24\pi k_B T_g \beta}{\mu m_p \kappa^2} \frac{r^3}{r^2 + r_c^2}.
$$

(69)

On the other hand, using equation (45) and (48) we can obtain another expression for the total mass

$$
\frac{dM_{tot}(r)}{dr} = 4\pi r^2 \rho_g(r) + \frac{48\pi}{\kappa^2 \lambda_6} U(r)r^2 + \frac{8\pi \kappa^2 \mu^2}{\kappa^2} \left[ P(r) + 3U(r) \right] r^2,
$$

(70)

substituting equations (69) and (65) into equation (70) we obtain the following expression

$$
\frac{12}{\kappa^2 \lambda_6} U(r) + \frac{2\kappa^2 \mu^2}{\kappa^2} \left[ P(r) + 3U(r) \right] = \frac{6k_B T_g \beta}{\mu m_p \kappa^2} \frac{r^2 + 3r_c^2}{(r^2 + r_c^2)^2} \rho_0 \left( 1 + \frac{r^2}{r_c^2} \right)^{-3\beta/2}.
$$

(71)
Finally, substituting above equation into equation (48), in the limit $r >> r_c$ considered here, we obtain the following geometrical mass

$$
\mathcal{M}(r) \simeq \left[ \frac{24\pi k_B T_g \beta}{\mu m_p \kappa_4^2} - 4\pi \rho_0 r_c^{3\beta} \frac{r^{2-3\beta}}{3(1-\beta)} \right] r,
$$

(72)

which includes both the local and non-local bulk effects. Observations show that the intra cluster gas has a small contribution to the total mass [31, 32, 33, 34], thus we can neglect the contribution of the gas to the geometrical mass and rewrite equations (72) as

$$
\mathcal{M}(r) \simeq \left( \frac{24\pi k_B T_g \beta}{\mu m_p \kappa_4^2} \right) r.
$$

(73)

Now let us estimate the value of $\mathcal{M}(r)$. First we note that $k_B T_g \approx 5\text{KeV}$ for most clusters. The virial radius of the clusters of galaxies is usually assumed to be $r_{200}$, indicating the radius for which the energy density of the cluster becomes $\rho_{200} = 200\rho_{cr}$, where $\rho_{cr} = 4.6975 \times 10^{-30}h_{50}^2\text{gr/cm}^3$ [32]. Using equation (72) we find

$$
r_{cr} = 91.33^{3/2} \left( \frac{k_B T_g}{5\text{KeV}} \right)^{1/2} h_{50}^{-1}\text{Mpc}.
$$

(74)

The total geometrical mass corresponding to this value is

$$
\mathcal{M}(r) = 4.83 \times 10^{16} \beta^{3/2} \left( \frac{k_B T_g}{5\text{KeV}} \right)^{1/2} h_{50}^{-1}\text{M}_\odot,
$$

(75)

which is consistent with the observational values for the virial mass of clusters [32].

### 5.2 Radial velocity dispersion in galactic clusters

Radial velocity dispersion in galactic clusters plays an important role in estimating the virial mass of the clusters. It can be expressed in terms of the virial mass as [34]

$$
M_V = \frac{3}{G} \sigma_1^2 R_V.
$$

(76)

Assuming that the velocity distribution in the cluster is isotropic, we have $\langle v^2 \rangle = \langle v_r^2 \rangle + \langle v_\theta^2 \rangle + \langle v_\phi^2 \rangle = 3\langle v_r^2 \rangle = 3\sigma_r^2$, the radial velocity dispersion $\sigma_r^2$ for clusters in warped DGP model can be obtained from equation (37) as

$$
\frac{d}{dr}(\rho \sigma_r^2) + \frac{1}{2} \rho \lambda' = 0,
$$

(77)

where $\sigma_1$ and $\sigma_r$ are related by $3\sigma_1^2 = \sigma_r^2$. On the other hand, by neglecting the cosmological constant the Einstein field equation (43) becomes

$$
\left(1 + \frac{\lambda_b}{6} \kappa_4^4 \mu^2 \right) \frac{1}{2r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial \lambda}{\partial r} \right) = \frac{\kappa_4^2}{2} \rho + \frac{\kappa_4^4 \mu^2}{2} \rho \left[ \mathcal{P}(r) + 3\mathcal{M}(r) \right] + \frac{6}{\kappa_4^4 \lambda_b} U(r).
$$

(78)

Integrating, we obtain

$$
\left(1 + \frac{\lambda_b}{6} \kappa_4^4 \mu^2 \right) \frac{1}{2} \left(r^2 \frac{\partial \lambda}{\partial r} \right) = \frac{\kappa_4^2}{8\pi} M(r) + \frac{\kappa_4^2}{8\pi} \mathcal{M}(r) + C_1,
$$

(79)

where $C_1$ is an integration constant. By eliminating $\lambda'$ from equations (77) and (79), we obtain

$$
\left(1 + \frac{\lambda_b}{6} \kappa_4^4 \mu^2 \right) \frac{d}{dr}(\rho \sigma_r^2) = -\frac{\kappa_4^2 M(r)}{8\pi r^2} \rho(r) - \frac{\kappa_4^2 M(r)}{8\pi r^2} \rho(r) - \frac{C_1}{r^2} \rho(r).
$$

(80)
Figure 2: Left, The radial velocity dispersion in warped DGP brane-world model and right, the same parameter in DGP brane-world scenario for the NGC 5813 cluster with $\beta = 0.766$, $r_{200} = 0.87 Mpc$, $r_c = 25 Kpc$, $k_B T_g = 0.52 K eV$ and $C_1 = 0.503, 1.005 \times 10^8, 2.011 \times 10^8 M_\odot$, $C_2 = 0.02, 0.03, 0.04 M_\odot Kpc^3$ for solid, dashed and dot-dashed curves, respectively.

Integration now gives the following solution

$$
\left(1 + \frac{\lambda_b}{6} \kappa_5^2 \mu^2\right) \sigma_r^2 = -\frac{1}{\rho} \int \frac{\kappa_5^2 M(r)}{8\pi r^2} \rho(r) dr - \frac{1}{\rho} \int \frac{\kappa_5^2 M(r)}{8\pi r^2} \rho(r) dr - \frac{1}{\rho} \int \frac{C_1}{r^2} \rho(r) dr - \frac{C_2}{\rho},
$$

(81)

where $C_2$ is an integration constant. For most clusters $\beta \geq \frac{2}{3}$ and therefore, in the limit $r \gg r_c$, the gas density profile (65) can be written as [23]

$$
\rho_g(r) = \rho_0 \left(\frac{r}{r_c}\right)^{-3\beta}, \quad \beta \geq \frac{2}{3}.
$$

(82)

Now, substituting equations (45), (73) and equation (82) into equation (81), for $\beta \neq 1$ we obtain

$$
\left(1 + \frac{\lambda_b}{6} \kappa_5^2 \mu^2\right) \sigma_r^2 = -\frac{\rho_0 \kappa_5^2}{12(1 - \beta)(1 - 3\beta)} r^2 \left(\frac{r}{r_c}\right)^{-3\beta} + \frac{k_B T_g}{\mu m_p} + \frac{C_1}{(1 + 3\beta) r} - \frac{C_2}{\rho_0} \left(\frac{r}{r_c}\right)^{3\beta},
$$

(83)

and for $\beta = 1$ we find

$$
\left(1 + \frac{\lambda_b}{6} \kappa_5^2 \mu^2\right) \sigma_r^2 = \frac{\rho_0 \kappa_5^2}{8} r_c^3 \left(\frac{1}{4r^4} + \frac{\ln r}{r^4}\right) \left(\frac{r}{r_c}\right)^3 + \frac{k_B T_g}{\mu m_p} + \frac{C_1}{4r} - \frac{C_2}{\rho_0} \left(\frac{r}{r_c}\right)^3.
$$

(84)

As is well-known, the simple form $\sigma_r^2(r) = B/(r + b)$ for the radial velocity dispersion and the relation $\rho(r) = A/r(r + a)^2$ for the density of the galaxies in cluster, with $B, b, a$ and $A$ constants, can be used to fit the observational data [34]. For $r \ll a$, $\rho(r) \approx A/r$, while for $r \gg a$, $\rho(r)$ behaves like $\rho(r) \approx A/r^3$. Here, our expression for $\sigma_r^2$ can be also used to fit the observational data. Therefore, the comparison of the observed velocity dispersion profiles of the galaxy clusters and the velocity dispersion profiles predicted by the warped DGP brane-world model may give a powerful method to discriminate between the different theoretical scenarios.

Finally, we compare the radial velocity dispersion in warped DGP brane-world model with the radial velocity dispersion in the other theoretical models. As we noted before for $\Lambda^{(5)} = \lambda_b = 0$, the warped DGP model reduce to the DGP model and equation (84) for $\beta = 1$ reduce to

$$
\sigma_r^2 = \frac{\rho_0 \kappa_5^2}{8} r_c^3 \left(\frac{1}{4r^4} + \frac{\ln r}{r^4}\right) \left(\frac{r}{r_c}\right)^3 + \frac{k_B T_g}{\mu m_p} + \frac{C_1}{4r} - \frac{C_2}{\rho_0} \left(\frac{r}{r_c}\right)^3,
$$

(85)

which is the radial velocity dispersion in DGP model, equation (65) in [19]. The radial velocity dispersion of galaxy clusters in Palatini $f(R)$ gravity for $\gamma = 3$, which is corresponding to $\beta = 1$, is also presented as [18]

$$
\sigma_r^2 = -r^3 \int \frac{F'}{2F} r^{-3} dr + \frac{k_B T_g}{\mu m_p} + \pi G \rho_0 \left(\frac{1}{4r} + \frac{\ln r}{r^4}\right) + \frac{c}{4r} - \frac{c'}{\rho_0 r^3},
$$

(86)
where \( F(R) = \frac{df(R)}{dR} \). For \( f(R) = R \) this relation reduces to

\[
\sigma_r^2 = \frac{\kappa_4^2 \rho_0}{8} \left( \frac{1}{4r} + \frac{\ln r}{r} \right) + \frac{k_B T_g}{\mu m_p} + c \frac{1}{4r} - c' \rho_0 r^3,
\]

which is equation (84) with \( 8\pi G = \kappa_4^2 \) and \( \Lambda^{(5)} = \lambda_b = 0 \). The same relation has also been obtained in Randall-Sundrum II model with this difference that the origin of geometrical mass in \( f(R) \) gravity is the extra terms in the Einstein-Hilbert action whereas in the latter is the global bulk effect. In figure 2 we have plotted the radial velocity dispersion for the cluster NGC 5813. The numerical values of it are in the ranges \( \beta = 0.766, r_c = 25Kpc, k_B T_g = 0.52Kev, r_{200} = 0.087Mpc \) and the radial velocity is about 240km/s [35]. As one can see the radial velocity dispersion in warped DGP brane-world is compatible with the observed profiles and for the same value of constants \( C_1 \) and \( C_2 \) is slower than the DGP brane-world model.

6 Conclusions

The virial theorem plays an important role in astrophysics because of its generality and wide range of applications. One of the important results which can be obtained with the use of the virial theorem is to derive the mean density of astrophysical objects such as galaxy clusters and it can be used to predict the total mass of the clusters of galaxies. In the present paper, using the collision-less Boltzmann equation, we have obtained the generalized virial theorem within the context of the warped DGP brane-world model. The additional geometric terms due to the induced curvature term on the brane and non-local bulk effect in the modified gravitational field equations provide an effective contribution to the gravitational energy, equation (44), which may be used to explain the well-known virial theorem mass discrepancy in clusters of galaxies. Finally, we have compared the virial theorem results with the observational data for galaxy cluster which can be obtained from the X-ray observation of the gas in the cluster and expressed the geometrical mass in term of observational quantities, like the temperature and the gas profile density.
