(Communicated by Alberto Bressan)

Abstract. Visco-Energetic solutions of rate-independent systems (recently introduced in [17]) are obtained by solving a modified time Incremental Minimization Scheme, where at each step the dissipation is reinforced by a viscous correction $\delta$, typically a quadratic perturbation of the dissipation distance. Like Energetic and Balanced Viscosity solutions, they provide a variational characterization of rate-independent evolutions, with an accurate description of their jump behaviour.

In the present paper we study Visco-Energetic solutions in the scalar-valued case and we obtain a full characterization for a broad class of energy functionals. In particular, we prove that they exhibit a sort of intermediate behaviour between Energetic and Balanced Viscosity solutions, which can be finely tuned according to the choice of the viscous correction $\delta$.

1. Introduction. Rate-independent evolution problems occur in several contexts. We refer the reader to the recent monograph [13] for a survey of rate-independent modeling and analysis in a wide variety of applications. The analytical theory of rate-independent evolutions encounters some mathematical challenges, which are apparent even in the simplest example, the doubly nonlinear differential inclusion

$$\partial \Psi(\dot{u}(t)) + D\mathcal{E}(t, u(t)) \ni 0 \quad \text{in} \ X^* \quad \text{for a.a.} \ t \in (a,b). \tag{DN}$$

Here $X^*$ is the dual of a finite-dimensional linear space $X$, $\dot{u}$ is the time derivative of the curve $u : (a,b) \to X$, $D\mathcal{E}$ is the (space) differential of a time-dependent energy functional $\mathcal{E} \in C^1([a,b] \times X; \mathbb{R})$ and $\Psi : X \to (0, +\infty)$ is a convex and nondegenerate dissipation potential, hereafter supposed positively homogeneous of degree 1.

It is well known that if the energy $\mathcal{E}(t, \cdot)$ is not strictly convex, one cannot expect the existence of an absolutely continuous solution to (DN), so that candidate solutions are expected to belong to the space of functions with bounded variation $BV([a,b]; X)$. This fact has motivated the development of various weak formulations of (DN), which should also take into account the behaviour of $u$ at jump points (see e.g. [9] for a detailed discussion and relevant examples).

Key words and phrases. Abstract evolution equations, rate-independent systems, energetic and BV solutions, Visco-Energetic solutions.

5883
Energetic solutions. The first is the notion of Energetic solutions, [15, 14, 8]. For the simplified rate-independent evolution (DN), Energetic solutions are curves $u : [a, b] \to X$ with bounded variation that are characterized by two variational conditions, called stability ($S_\Psi$) and energy balance ($E_\Psi$):

$$E(t, u(t)) \leq E(t, z) + \Psi(z - u(t)) \quad \text{for every } z \in X, \quad (S_\Psi)$$

$$E(t, u(t)) + \text{Var}_\Psi(u; [a, b]) = E(a, u(a)) + \int_a^t \partial_t E(s, u(s)) \, ds, \quad (E_\Psi)$$

where $\text{Var}_\Psi$ is the pointwise total variation with respect to $\Psi$ (see 2.1 in section 2 for the precise definition).

One of the strongest feature of the energetic approach is the possibility to construct energetic solutions by solving the time Incremental Minimization Scheme

$$\min_{U \in X} E(t_{n^\tau}, U) + \Psi(U - U_{n^\tau-1}). \quad (\text{IM}_\Psi)$$

If the energy $E$ has compact sublevels, then for every ordered partition $\tau = \{t_0^\tau = a, t_1^\tau, \ldots, t_{N-1}^\tau, t_N^\tau = b\}$ of the interval $[a, b]$ with variable time step $\tau_n := t_n^\tau - t_{n-1}^\tau$ and for every initial choice $U_0 = u(a)$ we can construct by induction an approximate sequence $(U^\tau_n)_{n=0}^N$ solving $(\text{IM}_\Psi)$. If $U^\tau_n$ denotes the left-continuous piecewise constant interpolant of $(U^\tau_n)_n$, then the family of discrete solutions $U^\tau$ has limit curves with respect to pointwise convergence as the maximum of the step sizes $|\tau|$ vanishes, and every limit curve $u$ is an energetic solution.

Consider for instance the 1-dimensional example when the energy has the form

$$E(t, u) := W(u) - \ell(t)u \quad \text{for a double-well potential such as } W(u) = (u^2 - 1)^2, \quad (1)$$

When the loading $\ell \in C^1([a, b])$ is strictly increasing, $\Psi(v) := \alpha|v|$ with $\alpha > 0$, and $u(a)$ is chosen carefully, it is possible to prove, [20], that an Energetic solution $u$ is an increasing selection of the equation

$$\alpha + W^*(u(t)) \ni \ell(t) \quad \text{for every } t \in [a, b], \quad (2)$$

where $W^*$ is the convex envelope of $W$, i.e. $W^*(u) = ((u^2 - 1)_+)^2$.

Figure 1. The double-well potential $W$ with its convex envelope in bold (left picture) and an energetic solution $u$ in the case of a strictly increasing load $\ell$ (right picture).
In this context, the solution \( u \) have a jump when the so-called Maxwell rule is satisfied:

\[
\int_{u^{-}(t)}^{u^{+}(t)} \left( W'(r) - \ell(t) + \alpha_+ \right) \, dr = 0,
\]

where \( u^{-}(t) \) and \( u^{+}(t) \) denote the left and the right limits of the function \( u \) (see section 2.1).

The latter evolution mode prescribes that for all \( t \in [a, b] \), the function \( u(t) \) only attains absolute minima of the function \( u \mapsto W(u) - (\ell(t) - \alpha_+)u \). This corresponds to a convexification of \( W \) and causes the system to jump “early”.

**Balanced Viscosity (BV) solutions.** The global stability condition \( S_\Psi \) may lead the system to change instantaneously in a very drastic way, jumping into far apart energetic configurations. In order to obtain a formulation where local effects are more relevant (see \([2, 18, 3]\)), a natural idea is to consider rate-independent apat energetic configurations. In order to obtain a formulation where local effects lead the system to change instantaneously in a very drastic way, jumping into far absolute minima attains local stability to prove that all the limit curves satisfy a description of the jump behaviour of \( u \).

Viscosity term (see e.g. the analysis of \([21, 5]\)).

The limit evolution, which at some extent also depends on the choice of the vanishing solutions \([19, 10, 11, 12]\), which provides a differential-variational characterization of the time Incremental Minimization Scheme:

\[
\min_{U \in X} \mathcal{E}(\tau^n U) + \Psi(U - U^n - 1) + \frac{\varepsilon^n}{2\tau^n} \Psi^2(U - U^n - 1).
\]

The choice \( \varepsilon^n = \varepsilon^n(\tau) \downarrow 0 \) with \( \varepsilon^n(\tau) \uparrow +\infty \) leads to the notion of Balanced Viscosity solutions \([19, 10, 11, 12]\), which provides a differential-variational characterization of the limit evolution, which at some extent also depends on the choice of the vanishing viscosity term (see e.g. the analysis of \([21, 9]\)).

Under suitable smoothness and lower semicontinuity assumptions, it is possible to prove that all the limit curves satisfy a local stability condition and a modified energy balance, involving an augmented total variation that encodes a more refined description of the jump behaviour of \( u \): roughly speaking, a jump between \( u^{-}(t) \) and \( u^{+}(t) \) occurs only when these values can be connected by a rescaled solution \( \vartheta \) of \( \text{(DN)} \), where the energy is frozen at the jump time \( t \)

\[
\partial \Psi(\vartheta(s)) + \vartheta(s) + D\mathcal{E}(t, \vartheta(s)) \ni 0.
\]

In the one-dimensional example \([1]\), with the loading \( \ell \) strictly increasing and under suitable choices of the initial datum, it is possible to prove, \([20]\), that \( u \) is a BV solution if and only if it is nondecreasing and

\[
\alpha + W'(u(t)) = \ell(t) \quad \text{for all } t \in [a, b] \setminus J_u,
\]

where \( J_u \) denotes the set of the jump points of the function \( u \).

The evolution mode \([3]\) follows the so called Delay rule, related to hysteresis behaviour. The system accepts also relative minima of \( u \mapsto W(u) - (\ell(t) - \alpha)u \), and thus the function \( t \mapsto u(t) \) tend to jump “as late as possible”.

**Visco-Energetic solutions and main results of the paper.** Recently, in \([17]\), the new notion of Visco-Energetic (VE) solutions has been proposed. This is a sort of intermediate situation between energetic and balanced viscosity, since these solutions are obtained by studying the time Incremental Minimization Scheme \( \text{(IM}\Psi,\varepsilon,\tau) \) when one keeps constant the ratio \( \mu := \varepsilon^n/\tau^n \), obtaining a moderate vanishing
Figure 2. BV solution for a double-well energy $W$ with an increasing load $\ell$. The blue line denotes the path described by the optimal transition $\vartheta$ solving (1).

viscosity, which can be only captured at the discrete level but does not have a continuous counterpart as for the vanishing-viscosity approximation $[\text{DN}_\varepsilon]$.

In this way the dissipation $\Psi$ is corrected by an extra viscous penalization term, for example of the form

$$\delta(u, v) := \frac{\mu}{2} \Psi^2(v - u)$$

which induces a stronger localization of the minimizers, according to the size of the parameter $\mu$. The new modified time Incremental Minimization Scheme is therefore

$$\min_{U \in X} \mathcal{E}(t^n_\tau, U) + \Psi(U - U_{n-1}^\tau) + \delta(U, U_{n-1}^\tau). \quad (\text{IM}_{\Psi, \delta})$$

As in the energetic and BV cases, a variational characterization of the functions obtained as a limit of the solution of $\text{(IM}_{\Psi, \delta})$ is possible, still involving a suitable stability condition and an energetic balance. Concerning stability, we have a natural generalization of $\text{(S}_{\Psi})$:

$$\mathcal{E}(t, u(t)) \leq \mathcal{E}(t, v) + \Psi(v - u(t)) + \delta(u(t), v) \quad \text{for every } v \in X, \ t \in [a, b] \setminus J_u. \quad (7)$$

The right replacement of the energy balance condition is harder to formulate. A heuristic idea, which one can figure out by the direct analysis of $\text{(1)}$, is that jump transitions between $u_k(t)$ and $u_{k+1}(t)$ should be described by discrete trajectories $\vartheta : Z \to X$ defined in a subset $Z \subset \mathbb{Z}$ such that each value $\vartheta(n)$ is a minimizer of the incremental problem $\text{(IM}_{\Psi, \vartheta})$, with datum $\vartheta(n - 1)$ and with the energy “frozen” at time $t$. In the simplest cases $Z = \mathbb{Z}$, the left and right jump values are the limit of $\vartheta(n)$ as $n \to \pm \infty$, but more complicated situations can occur, when $Z$ is a proper subset of $\mathbb{Z}$ or one has to deal with concatenation of (even countable) discrete transitions and sliding parts parametrized by a continuous variable, where the stability condition $\text{(7)}$ holds.

In order to capture all of these possibilities, VE transitions are parametrized by continuous maps $\vartheta : E \to X$ defined in an arbitrary compact subset of $\mathbb{R}$. We refer to section $\text{2.2}$ for the precise description of the new dissipation cost and the corresponding total variation.
In the present paper we study Visco-Energetic solutions in the one dimensional setting and we obtain a full characterization for the same broad class of energy functionals of \([20]\). Respect to Energetic and BV solutions, the main difficulty here comes from the description of solutions at jumps: as we have mentioned, transitions are now defined in an arbitrary compact subset of \(\mathbb{R}\), so that a wide range of possibilities can occur. For instance, the energetic case is a very particular situation, where (e.g. for an increasing jump) the transitions have the form

\[
\vartheta : \{0; 1\} \to \mathbb{R} \quad \text{such that} \quad \vartheta(0) = u_L(t), \quad \vartheta(1) = u_R(t),
\]

\(\vartheta\) defined in a compact set that consists just in two points.

However, thanks to an accurate analysis of VE dissipation cost, we are able to describe all these possibilities. Coming back to the standard example \([1]\), with the viscous correction \(\delta\) of the form \([6]\), the behaviour of VE solutions strongly depends on the parameter \(\mu\). More precisely, the following situations can occur:

- The viscous correction term is sufficiently strong, for example \(\mu \geq - \min W''\). In this case VE solutions exhibits a behaviour comparable to BV solutions: both satisfies the same local stability condition and equation \([5]\) holds, so that they follow a delay rule.
- No viscous corrections are added to the system, which corresponds to \(\mu = 0\). In this case VE solutions coincides with energetic solutions, equation \([2]\) holds and they satisfy the Maxwell rule.
- A “weak” viscous correction is added to the system, which corresponds to a small \(\mu > 0\). We have a sort of intermediate situation between the two previous cases: a jump can occur even before reaching a local extremum of \(W'\). In particular, an increasing jump can occur when the modified Maxwell rule is satisfied:

\[
\int_{u_L(t)}^{u_+} \left( W'(r) - \ell(t) + \alpha + \mu(r - u_L(t)) \right) \, dr = 0, \quad \text{for some } u_+ > u_L(t). \tag{9}
\]

In this case \(u_R(t)\) may differ from \(u_+\): see Figure 3 for more details.

The dependence of Visco-Energetic solutions on the particular choice of the viscous correction added to the incremental minimization scheme \([IMG]\) may lead to a considerable margin of arbitrariness in the construction and in the characterization of the obtained solutions. In this respect, the study of general principles inspiring a well funded choice of the discretization method would be extremely important.

On the other hand, one can also observe that an even more substantial gap exists between Energetic and Balanced Viscosity solutions. Since discontinuous phenomena are involved, it could be difficult to decide a-priori if a model based on global minimization is preferable to a vanishing viscosity approach (see e.g. \([7]\)). In many cases the choice of the best mathematical notion will be dictated by the need of a robust theory and a good phenomenological accordance with the model behaviour. In this respect, we think that the Visco-Energetic approach can reduce the gap between the available approaches, since it allows for a greater flexibility and offers a wider scale of models capturing a variety of responses, still in the framework of a robust variational theory and a simple discretization method, which theoretically reflects a natural numerical localization.

**Plan of the paper.** In the paper we will analyse VE solutions to one-dimensional rate-independent evolutions driven by general (nonconvex) potentials and we will
assume that the viscous corrections $\delta$ satisfies only the natural assumptions of the visco-energetic theory, including in particular the quadratic case (6).

In the preliminary section 2, we recall the main definitions of Visco-Energetic solutions, their dissipation cost and the corresponding total variation, along with some useful properties and characterizations coming from the general theory; all the assumptions of the one-dimensional setting are collected in section 2.4.

In section 3, after a brief discussion about the stability conditions, we give a characterizations of Visco-Energetic solutions with a general (i.e. non monotone) external loading. This characterization involves the one-sided global slopes with a $\delta$ correction, which are defined in section 3.1.

In section 4 we analyse the case of a monotone loading $\ell$. We exhibit a more explicit characterization of Visco-Energetic solutions, in term of the monotone envelopes of the one-sided global slopes. This characterization, in a suitable sense, generalizes (2) and (5).
2.1. **Rate-independent setting and BV functions.** In the finite dimensional setting, a rate-independent system usually consists in the triple \((X, \mathcal{E}, \Psi)\), where \(\mathcal{E}\) is a *time-dependent energy functional* and \(\Psi\) is a *dissipation potential*, satisfying the conditions

\[
\Psi : X \to [0, +\infty) \text{ is nondegenerate, convex and 1-positively homogeneous.} \quad (10)
\]

In the present paper we will assume the standard assumptions \(\square\) (from section \(\square\) (an even more particular case will be considered) and we choose energies of the form

\[
\mathcal{E}(t, u) := W(u) - \langle \ell(t), u \rangle,
\]

for some \(W \in C^1(X)\) bounded from below by a constant \(-\lambda > -\infty\) and \(\ell \in C^1([a, b]; X^*)\). We shall also use the notation \(\mathcal{P}(t, u) := \partial_t \mathcal{E}(t, u) = -\langle \ell'(t), u \rangle\) for the partial time derivative of \(\mathcal{E}\), and we set

\[
K^* := \partial\Psi(0) = \{ w \in X^* : \Psi_+(w) \leq 1 \} \subset X^*, \quad \text{where } \Psi_+(w) := \sup_{\Psi(v) \leq 1} \langle w, v \rangle.
\]

The rate-independent system associated with the energy functional \(\mathcal{E}\) and the dissipation potential \(\Psi\) can be formally described by the *rate-independent doubly nonlinear* differential inclusion \(\square\)

\[
\partial\Psi(\dot{u}(t)) + D\mathcal{E}(t, u(t)) \ni 0 \quad \text{in } X^* \quad \text{for a.a. } t \in (a, b).
\]

It is well known that for nonconvex energies, solutions to \(\square\) may exhibit discontinuities in time. Therefore, the natural space for candidate solutions \(u\) is the space of functions with bounded variation.

**Definition 2.1 (BV functions).** Let \(u : [a, b] \to \mathbb{R}\). We define the \((\psi-)\)pointwise total variation of the function \(u\) by

\[
\text{Var}_\psi(u; [a, b]) := \sup \left\{ \sum_{m=1}^{M} \Psi(u(t_m) - u(t_{m-1})) : a = t_0 < t_1 < \cdots < t_M = b \right\}
\]

and we say that \(u\) belongs to the space \(\text{BV}([a, b]; X)\) of functions with *bounded variation* if \(\text{Var}_\psi(u; [a, b]) < +\infty\).

Notice that a function \(u \in \text{BV}([a, b]; X)\) admits left and right limits at every \(t \in [a, b]\):

\[
u_L(t) := \lim_{s \downarrow t} u(s), \quad u_R(t) := \lim_{s \uparrow t} u(s), \quad \text{with } u_L(a) := u(a) \text{ and } u_R(b) := u(b) \quad (14)
\]

and its pointwise jump set \(J_u\) is the at most countable set defined by

\[
J_u := \{ t \in [a, b] : u_L(t) \neq u_R(t) \text{ or } u_L(t) \neq u_R(t) \} \ni
\]

\[
\text{ess-J}_u := \{ t \in (a, b) : u_L(t) \neq u_R(t) \}. \quad (15)
\]

We denote by \(\dot{u}\) the distributional derivative of \(u\) (extended by \(u(a) \in (-\infty, a)\) and by \(u(b) \) in \((b, +\infty)\)) : it is a Radon vector measure with finite total variation \(|\dot{u}|\) supported in \([a, b]\). It is well known, \(\square\), that \(\dot{u}\) can be decomposed into the sum of its diffuse part \(\dot{u}_{co}\) and its jump part \(\dot{u}_{J}\):

\[
\dot{u} = \dot{u}_{co} + \dot{u}_{J}, \quad \dot{u}_{\text{ess-J}_u}, \quad \text{so that } \dot{u}_{co}(\{t\}) = 0 \text{ for every } t \in [a, b].
\]
2.2. Visco-Energetic (VE) solutions in the finite-dimensional case. We recall the notion of Visco-Energetic solutions for the finite-dimensional setting introduced in section 2.1. As mentioned in the introduction, the first crucial ingredient is the viscous correction, namely a continuous map \( \delta : X \times X \to [0, +\infty) \), and its associated augmented dissipation

\[
D(u, v) := \Psi(v - u) + \delta(u, v) \quad \text{for every } u, v \in X.
\]  

(16)

In order to stress the importance of this viscous correction \( \delta \), hereafter we will prefer to speak about Rate-Independent visco-energetic Systems (abbreviated in RIveS) and to denote them with the quadruple \( (X, E, \Psi, \delta) \). As in the energetic framework (see e.g. [13, 14, 8]), Visco-Energetic solutions of Rate-Independent visco-energetic Systems are curves \( u : [a, b] \to X \) with bounded variation that are characterized by a stability condition and an energetic balance.

Concerning stability, we have a similar inequality, but we have to replace \( \Psi \) with the augmented dissipation \( D \). More precisely, we will require that for every \( t \in J_u \)

\[
E(t, u(t)) \leq E(t, v) + D(u(t), v) \quad \text{for every } v \in X,
\]

(SD)

which is naturally associated with the D stable set \( S_D \).

**Definition 2.2 (D-stable set).** The D-stable set is the subsets of \([a, b] \times X\)

\[
S_D := \{ (t, u) : E(t, u) \leq E(t, v) + D(u, v) \quad \text{for every } v \in X \}.
\]

(17)

Its section at time \( t \) will be denoted with \( S_D(t) \).

The energetic balance is harder to formulate than stability and it requires some additional conditions on the viscous correction term \( \delta \). A full description of Visco-Energetic solutions and admissible viscous corrections is discussed in [17], where the general metric-topological setting is considered. In this section, we will assume that \( \delta \) satisfies the following assumption

\[
\lim_{v \to u} \frac{\delta(u, v)}{\Psi(v - u)} = 0 \quad \text{for every } u \in S_D(t), \ t \in [a, b],
\]

(18)

which is a general condition that includes, for instance, the quadratic case discussed in the introduction. Moreover, we need to introduce two other key concepts: the transition cost and the augmented total variation associated with the dissipation \( D \).

Hereafter, for every subset \( E \subset \mathbb{R} \) we call \( E^- := \inf E, E^+ := \sup E \); whenever \( E \) is compact, we will denote by \( \mathcal{P}(E) \) the (at most) countable collection of the connected components of the open set \( [E^-, E^+] \setminus E \). We also denote by \( \mathcal{P}_f(E) \) the collection of all finite subsets of \( E \).

Concerning the transition cost, the main point here is to consider transitions parametrized by continuous maps \( \vartheta : E \to X \) defined in arbitrary compact subsets of \( \mathbb{R} \) such that \( \vartheta(E^-) = u_L(t) \) and \( \vartheta(E^+) = u_R(t) \). More precisely, the first ingredient is the residual stability function:

**Definition 2.3 (Residual stability function).** For every \( t \in [a, b] \) and \( u \in X \) the residual stability function is defined by

\[
\mathcal{R}(t, u) := \sup_{v \in X} \{ E(t, u) - E(t, v) - D(u, v) \}
\]

(19)

\[
= E(t, u) - \inf_{v \in X} \{ E(t, v) + D(u, v) \}.
\]

(20)
\( \mathcal{R} \) provides a measure of the failure of the stability condition \([[30]]\). Since for every \( u \in X, t \in [a, b] \) we get
\[
\mathcal{E}(t, u) \leq \mathcal{E}(t, v) + D(u, v) + \mathcal{R}(t, u)
\]
and
\[
\mathcal{R}(t, u) = 0 \iff u \in \mathcal{S}_D(t).
\]

The transition cost is the sum of three contributions, accordingly with the following definition.

**Definition 2.4** (Transition cost). Let \( E \subset \mathbb{R} \) compact and \( \vartheta \in C(E; X) \). For every \( t \in [a, b] \) we define the transition cost function \( \text{Trc}(t, \vartheta, E) \) by
\[
\text{Trc}(t, \vartheta, E) := \text{Var}_\vartheta(\vartheta, E) + \text{GapVar}_\vartheta(\vartheta, E) + \sum_{s \in E \setminus \{E^+\}} \mathcal{R}(t, \vartheta(s))
\]
where the first term is the usual total variation (see \([21]\), the second one is
\[
\text{GapVar}_\vartheta(\vartheta, E) := \sum_{I \in \mathcal{S}(E)} \delta(\vartheta(I^-), \vartheta(I^+)),
\]
and the third term is
\[
\sum_{s \in E \setminus \{E^+\}} \mathcal{R}(t, \vartheta(s)) := \sup \left\{ \sum_{s \in P} \mathcal{R}(t, \vartheta(s)) : P \in \mathfrak{P}(E \setminus \{E^+\}) \right\},
\]
with the sum defined as 0 if \( E \setminus \{E^+\} = \emptyset \).

We adopt the convention \( \text{Trc}(t, \vartheta, \emptyset) := 0 \). It is not difficult to check that the transition cost \( \text{Trc}(t, \vartheta, E) \) is additive with respect to \( E \):
\[
\text{Trc}(t, \vartheta, E \cap [a, c]) = \text{Trc}(t, \vartheta, E \cap [a, b]) + \text{Trc}(t, \vartheta, E \cap [b, c]) \quad \text{for every } a < b < c.
\]

It has been proved, \([17] \) Theorem 6.3, that for every \( t \in [a, b] \) and for every \( \vartheta \in C(E; X) \)
\[
\mathcal{E}(t, \vartheta(E^+)) + \text{Trc}(t, \vartheta, E) \geq \mathcal{E}(t, \vartheta(E^-)).
\]
The dissipation cost \( c(t, u_0, u_1) \) induced by the function \( \text{Trc} \) is defined by minimizing \( \text{Trc}(t, \vartheta, E) \) among all the transitions \( \vartheta \) connecting \( u_0 \) to \( u_1 \):

**Definition 2.5** (Jump dissipation cost and augmented total variation). Let \( t \in [a, b] \) be fixed and let us consider \( u_0, u_1 \in X \). We set
\[
c(t, u_0, u_1) := \inf \left\{ \text{Trc}(t, \vartheta, E) : E \subset \mathbb{R}, \ \vartheta \in C(E; X), \ \vartheta(E^-) = u_0, \ \vartheta(E^+) = u_1 \right\},
\]
with the incremental dissipation cost \( \Delta_c(t, u_0, u_1) := c(t, u_0, u_1) - \Psi(u_1 - u_0) \). We also define
\[
\text{Jmp}_{\Delta_c}(u, [a, b]) := \Delta_c(a, u(a), u_b(a)) + \sum_{t \in J_a \cap (a, b)} \Delta_c(t, u_b(t), u(t)),
\]
and the corresponding augmented total variation \( \text{Var}_{\vartheta, \Delta_c} \) is then
\[
\text{Var}_{\vartheta, \Delta_c}(u, [a, b]) := \text{Var}_{\vartheta}(u, [a, b]) + \text{Jmp}_{\Delta_c}(u, [a, b]).
\]
The infimum in \([26]\) is attained whenever there is at least one admissible transition \( \vartheta \) with finite cost. In this case, we say that \( \vartheta \) is an *optimal transition*. 
Definition 2.6 (Optimal transitions). Let \( t \in [a,b] \) and \( u_-, u_+ \in X \). We say that a curve \( \vartheta \in C(E; X) \), \( E \) being a compact subset of \( \mathbb{R} \), is an optimal transition between \( u_- \) and \( u_+ \) if
\[
\begin{align*}
&u_- = \vartheta(E^-), \quad u_+ = \vartheta(E^+), \quad c(t, u_-, u_+) = \text{Trc}(t, \vartheta, E). \\
&\vartheta \text{ is tight if, for every } I \in \mathcal{I}(E), \vartheta(I^-) \neq \vartheta(I^+). \quad (29)
\end{align*}
\]
\[
\begin{align*}
&\text{pure jump transition, if } E \setminus \{E^-, E^+\} \text{ is discrete,} \quad (30) \\
&\text{sliding transition, if } R(t, \vartheta(r)) = 0 \quad \text{for every } r \in E, \quad (31) \\
&\text{viscous transition, if } R(t, \vartheta(r)) > 0 \quad \text{for every } r \in E \setminus \{E^\pm\}. \quad (32)
\end{align*}
\]

Notice that if \( \vartheta \) is a transition with a finite cost, i.e. \( \text{Trc}(t, \vartheta, E) < \infty \), then the set
\[
E_R := \{r \in E \setminus E^+ : R(t, \vartheta(r)) > 0\} \quad \text{is discrete, i.e. all its points are isolated.} \quad (33)
\]

With these notions at our disposal, we can now give the precise definition of Visco-Energetic solutions of the RIveS \((X, E, \Psi, \delta)\).

Definition 2.7 (Visco-Energetic solutions). We say that a curve \( u \in BV([a,b]; X) \) is a Visco-Energetic (VE) solution of the RIveS \((X, E, \Psi, \delta)\) if it satisfies the stability condition
\[
u(t) \in S_D(t) \quad \text{for every } t \in [a,b] \setminus J_u, \quad (S_D)
\]
and the energetic balance
\[
\mathcal{E}(t, u(t)) + \text{Var}_{\Psi, \mathcal{E}}(u, [a,t]) = \mathcal{E}(a, u(a)) + \int_a^t P(s, u(s)) \, ds \quad (E_{\Psi, \mathcal{E}})
\]
for every \( t \in [a,b] \).

Existence of Visco-Energetic solutions in a much more general metric-topological setting is proved in [17]. Solutions are obtained as a limit of piecewise constant interpolant of discrete solutions \( U_n^{\tau} \) obtained by recursively solving the modified time Incremental Minimization Scheme
\[
\min_{U \in X} \mathcal{E}(t_n^{\tau}, U) + D(U_{n-1}^{\tau}, U). \quad (\text{IM}_D)
\]
starting from an initial datum \( U_0^{\tau} \approx u_0 \).

2.3. Some useful properties of VE solutions. In this section we collect a list of useful properties of Visco-Energetic solutions and we prove an equivalent characterization in the finite-dimensional setting, involving a doubly nonlinear evolution equation. For more details about these results and their proof we refer to [17, 16].

To simplify the notation, we first introduce the Minimal set, which is related to the connection of two points through a step of Minimizing Movements.

Definition 2.8 (Moreau-Yosida regularization and Minimal set). Suppose that \( \mathcal{E} \) satisfies (47) and (48). The D-Moreau-Yosida regularization \( \mathcal{Y} : [a,b] \times \mathbb{R} \to \mathbb{R} \) of \( \mathcal{E} \) is defined by
\[
\mathcal{Y}(t, u) := \min_{v \in \mathbb{R}} \mathcal{E}(t, v) + D(u, v). \quad (34)
\]
For every \( t \in [a,b] \) and \( u \in \mathbb{R} \) the minimal set is
\[
M(t, u) := \text{argmin}_{v \in \mathbb{R}} \mathcal{E}(t, \cdot) + D(u, \cdot) = \left\{ v \in \mathbb{R} : \mathcal{E}(t, v) + D(u, v) = \mathcal{Y}(t, u) \right\}. \quad (35)
\]
Notice that, by \([47]\) and \([48]\), \(M(t,u) \neq \emptyset\) for every \(t,u\). It is also clear that \(\mathcal{R}(t,u) = \mathcal{E}(t,u) - \mathcal{Y}(t,u)\) and that

\[ u \in \mathcal{S}(t) \implies u \in M(t,u). \]

As we have mentioned in the introduction, when \(t \in J_u\) and \(\vartheta : E \to \mathbb{R}\) is an optimal transition between \(u(t)\) and \(u_0(t)\), \(\vartheta\) “keeps trace” of the whole construction via \([LM_0]\). For instance, when \(\vartheta(E)\) is discrete, every point is obtained with a step of Minimizing Movements from the previous one, with the energy frozen the time \(t\). The next result, \([17, \text{Theorem } 3.16]\), formalises this property and characterizes Visco-Energetic optimal transitions. Whenever a set \(E \subset \mathbb{R}\) is given, we will use the notation

\[ r_E^- := \sup\{E \cap (-\infty, r)\} \cup \{E^-\}, \quad r_E^+ := \inf\{E \cap (r, +\infty)\} \cup \{E^+\}. \quad (36) \]

**Theorem 2.9.** A curve \(\vartheta \in C(E,\mathbb{R})\) with \(\vartheta(E) \ni u(t)\) is an optimal transition between \(u(t)\) and \(u_0(t)\) satisfying

\[ \mathcal{E}(t,u(t)) - \mathcal{E}(t,u_0(t)) = \text{Var}(t,\vartheta,E) \quad (37) \]

if and only if it satisfies

\[ \text{Var}(\vartheta,E \cap [r_0,r_1]) \leq \mathcal{E}(t,\vartheta(r_0)) - \mathcal{E}(t,\vartheta(r_1)) \quad \text{for every } r_0,r_1 \in E, \ r_0 \leq r_1, \quad (38) \]

and

\[ \vartheta(r) \in M(t,\vartheta(r_E^-)) \quad \text{for every } r \in E \setminus \{E^-\}. \quad (39) \]

In some situations, the first inequality \([37]\) can be proved thanks to the following elementary lemma, whose proof is analogous to \([17, \text{Lemma } 6.1]\)

**Lemma 2.10.** Let \(E \subset \mathbb{R}\) be a compact set with \(E^- < E^+\), let \(L(E)\) be the set of limit points of \(E\). We consider a function \(f : E \to \mathbb{R}\) lower semicontinuous and continuous on the left and a function \(g \in C(E)\) strictly increasing, satisfying the following two conditions:

i) for every \(I \in \mathfrak{S}(E)\)

\[ f(I^+) - f(I^-) \geq 1; \quad (40) \]

ii) for every \(t \in L(E)\) which is an accumulation point of \(L(E) \cap (-\infty, t)\) we have

\[ \limsup_{s \uparrow t, \, s \in L(E)} \frac{f(t) - f(s)}{g(t) - g(s)} \geq 1. \quad (41) \]

Then the map \(s \mapsto f(s) - g(s)\) is non decreasing in \(E\); in particular

\[ f(E^+) - f(E^-) \geq g(E^+) - g(E^-). \quad (42) \]

The following proposition, a consequence of \([25]\), is useful to prove existence of VE solutions since it gives some sufficient conditions.

**Proposition 1** (Sufficient criteria for VE solutions). Let \(u \in BV([a,b];X)\) be a curve satisfying the stability condition \([50]\). Then \(u\) is a VE solution of the \(R\)esS \((X,\mathcal{E},\Psi,\delta)\) if and only if it satisfies one of the following equivalent characterizations:

i) \(u\) satisfies the \((\Psi,c)\)-energy-dissipation inequality

\[ \mathcal{E}(b,u(b)) + \text{Var}_{\mathcal{E}}(u,[a,b]) \leq \mathcal{E}(a,u(a)) + \int_a^b \mathcal{P}(s,u(s))ds. \quad (43) \]
ii) $u$ satisfies the $d$-energy-dissipation inequality

$$E(t, u(t)) + \text{Var}_\Psi(u, [s, t]) \leq E(s, u(s)) + \int_s^t P(r, u(r)) \, dr \quad \text{for all } s \leq t \in [a, b] \quad (44)$$

and the following jump conditions at each point $t \in J_u$

$$E(t, u(t^-)) - E(t, u(t)) = c(t, u(t^-), u(t)),$$
$$E(t, u(t)) - E(t, u(t^+)) = c(t, u(t), u(t^+)), \quad (J_{VE})$$
$$E(t, u(t^-)) - E(t, u(t^+)) = c(t, u(t^-), u(t^+)).$$

Another simple property concerns the behaviour of Visco-Energetic solutions with respect to restrictions and concatenation. The proof is trivial.

**Proposition 2** (Restriction and concatenation principle). The following properties hold:

1. The restriction of a Visco-Energetic solution in $[a, b]$ to an interval $[\alpha, \beta] \subseteq [a, b]$ is a Visco-Energetic solution in $[\alpha, \beta]$;
2. If $a = t_0 < t_1 < t_{m-1} < t_m = b$ is a subdivision of $[a, b]$ and $u : [a, b] \to \mathbb{R}$ is Visco-Energetic solution on each one of the intervals $[t_{j-1}, t_j]$, then $u$ is a Visco-Energetic solution in $[a, b]$.

In our finite-dimensional setting it is possible to give another sufficient criterium for Visco-Energetic solutions, more precisely a characterization through the stability condition $(S_D)$, a doubly nonlinear differential inclusion, and the Jump condition $(J_{VE})$. This result will be the starting point for our discussion in the one-dimensional case.

**Theorem 2.11** (Characterization of VE solutions). A curve $u \in \text{BV}([a, b]; X)$ is a Visco-Energetic solution of the RIveS $(X, E, \Psi, \delta)$ if and only if it satisfies the stability condition $(S_D)$, the doubly nonlinear differential inclusion

$$\partial \Psi \left( \frac{d\dot{u}_{co}}{d\mu}(t) \right) + D\!W(u(t)) \ni \ell(t) \quad \text{for } \mu\text{-a.e. } t \in (a, b), \quad \mu := \mathcal{L}^1 + |\dot{u}_{co}| \quad (DN_0)$$

and the jump conditions $(J_{VE})$ at every $t \in J_u$:

$$E(t, u(t^-)) - E(t, u(t)) = c(t, u(t^-), u(t)), $$
$$E(t, u(t)) - E(t, u(t^+)) = c(t, u(t), u(t^+)), \quad (J_{VE})$$
$$E(t, u(t^-)) - E(t, u(t^+)) = c(t, u(t^-), u(t^+)).$$

**Proof.** From the definition of the viscous dissipation cost $c(t, u(t), u_{co}(t))$, it is immediate to check that

$$\text{Var}_\Psi(u, [a, b]) \leq \text{Var}_\Psi,c(u, [a, b]),$$

so that Visco-Energetic solutions are in particular local solutions, in the sense of [11]. This differential characterization is therefore an immediate consequence of Proposition [1] and [11] Proposition 2.7.

2.4. **The one-dimensional setting.** From now on we consider the particular case $X = \mathbb{R}$, which we also identify with $X^\ast$. We will denote by $v^+$, $v^-$ the positive and the negative part of $v \in \mathbb{R}$.
Dissipation. A dissipation potential is a function of the form 
\[ \Psi(v) := \alpha_+ v^+ + \alpha_- v^-, \quad v \in \mathbb{R}, \] for some \( \alpha_+, \alpha_- > 0 \). (45)
Hence, we have
\[ \partial \Psi(v) = \begin{cases} 
\alpha_+ & \text{if } v > 0, \\
[-\alpha_-, \alpha_+] & \text{if } v = 0, \\
-\alpha_- & \text{if } v < 0
\end{cases} \quad \text{for all } v \in \mathbb{R}, \] and
\[ K^* = [-\alpha_-, \alpha_+] \quad \Psi^*(w) = \frac{1}{\alpha_+} w^+ + \frac{1}{\alpha_-} w^- \quad \text{for all } w \in \mathbb{R}. \] (46)
Energy functional. The energy is given by a function \( E : [a,b] \times \mathbb{R} \to \mathbb{R} \) of the form
\[ E(t, u) := W(u) - \ell(t) u \] with \( \ell \in C^1([a,b]) \) and \( W : \mathbb{R} \to \mathbb{R} \) such that
\[ W \in C^1(\mathbb{R}), \quad \lim_{x \to -\infty} W'(x) = -\infty, \quad \lim_{x \to +\infty} W'(x) = +\infty. \] (48)
Viscous correction. The admissible one-dimensional viscous correction is a continuous map \( \delta : \mathbb{R} \times \mathbb{R} \to [0, +\infty) \) which satisfies
\[ \lim_{v \to u} \delta(u,v)_{|v-u|} = 0 \quad \text{for every } u \in \mathcal{D}(t), \quad t \in [a,b], \] (\( \delta_1 \)) and the reverse triangle inequality
\[ \delta(u_0, u_1) > \delta(u_0, v) + \delta(v, u_1) \quad \text{for every } u_0 < v < u_1. \] (\( \delta_2 \))
We still use the notation \( D(u,v) := \Psi(v-u) + \delta(u,v) \) for the augmented dissipation.

Remark 1 (Admissible viscous corrections). Assumption \( \delta_1 \) is necessary for the general theory of Visco-Energetic solutions; \( \delta_2 \) will be crucial for our one-dimensional characterization (see section 3.3). However, these assumptions are quite natural: they are satisfied, for example, if we choose \( \delta \) of the form
\[ \delta(u,v) = f(\Psi(v-u)) \quad \text{with } f \text{ positive, strictly convex, with } \lim_{r \to 0} \frac{f(r)}{r} = 0. \]
For instance, the standard choice \( \delta(u,v) = \frac{\mu}{2} (v-u)^2 \), for some positive parameter \( \mu \), is admissible. This particular case will be analysed with some example in sections 3 and 4.

3. Visco-Energetic solutions of rate-independent systems in \( \mathbb{R} \). As we have underlined in the introduction, Visco-Energetic solutions of the RIVEs \( \mathcal{R}(\mathbb{R}, \mathcal{E}, \Psi, \delta) \) are intermediate between energetic, which correspond to the choice \( \delta \equiv 0 \), and Balanced Viscosity solutions, which corresponds to a choice of \( \delta = \delta_\tau \), depending of \( \tau \), in (IMD) of the form
\[ \delta_\tau(u,v) := \mu(|\tau|) \delta(u,v), \quad \mu : (0, +\infty) \to (0, +\infty), \quad \lim_{r \to 0} \mu(r) = +\infty. \]
Guided by the characterizations of this two cases, given in [20] in a similar one-dimensional setting and recalled in the introduction, we obtain a full characterization for the visco-energetic case. In particular, the main results of [20] can be recover for some choices of \( \delta \).
3.1. One-sided global slopes with a $\delta$ correction. One-sided global slopes are used in [20] to give a one-dimensional characterization of Energetic solutions of rate-independent systems. We recall their definitions:

$$W'_r(u) := \inf_{z > u} \frac{W(z) - W(u)}{z - u}, \quad W'_s(u) := \sup_{z < u} \frac{W(z) - W(u)}{z - u}, \quad (49)$$

where the subscripts $ir$ and $sl$ stands for $inf$-$right$ and $sup$-$left$ respectively.

In this section we introduce a generalization of $W'_r$ and $W'_s$, and we prove some important properties. These slopes allow us to give an equivalent, one-dimensional, characterization of the $D$-Stability $\left(\mathcal{S}_D\right)$.

**Definition 3.1.** For every $u \in \mathbb{R}$ we define the one-sided global slopes with a $\delta$ correction

$$W'_{ir,\delta}(u) := \inf_{z > u} \left\{ \frac{1}{z - u} \left(W(z) - W(u) + \delta(u,z)\right) \right\}, \quad (50)$$

$$W'_{sl,\delta}(u) := \sup_{z < u} \left\{ \frac{1}{z - u} \left(W(z) - W(u) + \delta(u,z)\right) \right\}. \quad (51)$$

For simplicity, we will still use the notation $W'_r$ and $W'_s$ instead of $W'_{ir,0}$ and $W'_{sl,0}$ when $\delta \equiv 0$. From [41] it follows that the modified global slopes satisfy

$$W'_{ir,\delta}(u) \leq W'(u) \leq W'_{sl,\delta}(u), \quad \text{for every } u \in \mathbb{R} \quad (52)$$

and it is not difficult to check they are continuous. Indeed, it is sufficient to introduce the continuous function $V : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$

$$V(u,z) := \left\{ \begin{array}{ll} W'(u) & \text{if } z = u, \\ \frac{1}{z-u} \left(W(z) - W(u) + \delta(u,z)\right) & \text{if } z \neq u, \end{array} \right. \quad (53)$$

and observe, e.g. for $W'_{ir,\delta}$, that

$$W'_{ir,\delta}(u) = \min \{V(u,z) : z \geq u\}$$

and for $u$ in a bounded set the minimum is attained in a compact set thanks to [48].

If $\delta$ is big enough, in a suitable sense, equalities hold in (52). An important result is stated in the following proposition.

**Proposition 3.** Suppose that $W$ satisfies the $\delta$-convexity assumption

$$W(v) \leq (1 - t)W(u) + tW(w) + t(1 - t)\delta(u,w), \quad v = (1 - t)u + tw, \quad t \in [0,1]. \quad (53)$$

Then the one-sided slopes coincide with the usual derivative:

$$W'_{ir,\delta}(u) = W'(u) = W'_{sl,\delta}(u) \quad \text{for every } u \in \mathbb{R}. \quad \text{Proof.} \quad \text{We prove the first equality since the second one is analogous. Let us take } v, w \in \mathbb{R} \text{ with } u < v \leq w \text{ and } t \in (0,1) \text{ such that } v = (1 - t)u + tw. \text{ Then}$$

$$\frac{W(v) - W(u)}{v - u} \leq \frac{(1 - t)W(u) + tW(w) + t(1 - t)\delta(u,w) - W(u)}{t(w - u)} = \frac{W(w) - W(u) + \delta(u,w) - t\delta(u,w)}{w - u} \leq \frac{W(w) - W(u) + \delta(u,w)}{w - u}. \quad (54)$$

Passing to the limit as $v \downarrow u$ we get

$$W'(u) \leq \frac{W'(w) - W'(u) + \delta(u,w)}{w - u} \quad \text{for every } w > u.$$
Now it is enough to take the infimum over $w > u$. \hfill $\Box$

**Remark 2.** An interesting consequence of Proposition $\overline{3}$ is that if $W$ satisfies the usual $\lambda$-convexity assumption

$$W(v) \leq (1-t)W(u) + tW(w) - \lambda t(1-t)(w-u)^2, \quad v = (1-t)u + tw, \quad t \in [0,1]$$

(54)

for some $\lambda \in \mathbb{R}$, then for every $\mu \geq \min\{-\lambda,0\}$ we can choose $\delta(u,w) := \mu(w-u)^2$ and (53) holds. In particular, if $W$ is convex, for every admissible viscous correction $\delta$ the one-sided global slopes coincide with the usual derivative.

If $W'_{\delta}(u) < W'(u)$ in a point $u \in \mathbb{R}$, then from (48) there exists $z > u$ which attains the infimum in (50). The same happens if $W'_{\delta}(u) > W'(u)$. Moreover, from the continuity of $W$ and of the global slopes, there exists a neighborhood of $u$ in which the strict inequality holds. In this neighborhood $W'_{\delta}$, or $W'_{\delta}$, are decreasing.

**Proposition 4.** Let $I \subseteq \mathbb{R}$ be an open interval such that

$$W'_{\delta}(v) < W'(v) \quad (resp. \quad W'_{\delta}(v) > W'(v)) \quad \text{for every } v \in I.$$ Then $W'_{\delta}$ (resp. $W'_{\delta}$) is decreasing on $I$.

**Proof.** Let $v_1 \in I$ and let $z > v_1$ be an element that attains the infimum in (50). Then for every $v_2 < z$ we have the inequality

$$W'_{\delta}(v_2) - W'_{\delta}(v_1) \leq \frac{W(z) - W(v_2) + \delta(v_2,z)}{z - v_2} - \frac{W(z) - W(v_1) + \delta(v_1,z)}{z - v_1}.$$

From (52), $\delta(v_1,z) \geq \delta(v_2,z)$ so that

$$\frac{1}{v_2 - v_1} \left[ \frac{\delta(v_2,z)}{z - v_2} - \frac{\delta(v_1,z)}{z(v_1) - v_1} \right] \leq \frac{\delta(v_2,z)}{(z - v_2)(z - v_1)}.$$ Combining this with the simple identity

$$\frac{W(z) - W(v_1)}{z - v_1} = \frac{W(z) - W(v_2)}{z - v_2} \left( 1 - \frac{v_2 - v_1}{z - v_1} \right) + \frac{W(v_2) - W(v_1)}{v_2 - v_1} \frac{v_2 - v_1}{z - v_1}$$

after a simple computation we obtain

$$\frac{W'_{\delta}(v_2) - W'_{\delta}(v_1)}{v_2 - v_1} \leq \frac{1}{z - v_1} \left[ \frac{W(z) - W(v_2) + \delta(v_2,z)}{z - v_2} - \frac{W(v_2) - W(v_1)}{v_2 - v_1} \right].$$

Passing to the limsup for $v_2 \downarrow v_1$ we get

$$\limsup_{v_2 \downarrow v_1} \frac{W'_{\delta}(v_2) - W'_{\delta}(v_1)}{v_2 - v_1} \leq \frac{1}{z - v_1} \left( W'_{\delta}(v_1) - W'(v_1) \right) < 0.$$ The claim follows from a classical result concerning Dini derivatives, see $[4]$. \hfill $\Box$

**Characterizations of $D$-Stability.** Taking $\overline{50}$ and $\overline{51}$ into account, we can formulate a characterization of the global $D$-stability $S_D$. Since the energy is of the form $\mathcal{E}(t, u) = W(u) - \ell(t)u$, $S_D$ is equivalent to

$$W(u(t)) - W(v) - \ell(t)(u(t) - v) \leq \Psi(v - u) + \delta(u,v) \quad \text{for every } t \in [a,b] \setminus J, \quad v \in \mathbb{R}.$$ Dividing by $u(t) - v$ and taking the infimum over $v > u(t)$, or the supremum over $v < u(t)$, for every $t \in [a,b] \setminus J$, we get the system of inequalities

$$-\alpha_+ \leq \ell(t) - W'_{\delta}(u(t)) \leq \ell(t) - W'(u(t)) \leq \ell(t) - W'_{\delta}(u(t)) \leq \alpha_+, \quad (S_{D,\mathbb{R}})$$

$$-\alpha_- \leq \ell(t) - W'_{\delta}(u(t)) \leq \ell(t) - W'(u(t)) \leq \ell(t) - W'_{\delta}(u(t)) \leq \alpha_-, \quad (S_{D,\mathbb{R}})$$
which are the one-dimensional version of the global D-stability. The continuity property of the \( \delta \)-corrected one-sided slopes also yields for every \( t \in (a, b) \)

\[ -\alpha_- \leq \ell(t) - W^\prime_{\text{sl}, \delta}(u_0(t)) \leq \ell(t) - W^\prime(\delta + u_0(t)) < \alpha_+ , \]  

\( (55) \)

\[ -\alpha_- \leq \ell(t) - W^\prime_{\text{ir}, \delta}(u_0(t)) \leq \ell(t) - W^\prime(\delta + u_0(t)) < \alpha_+ . \]  

\( (56) \)

**Remark 3.** The stability region \( \mathcal{S}_D \) is bigger when \( \delta \) increases. If we call

\[ \mathcal{S}_\infty := \{(t, u) \in [a, b] \times \mathbb{R} : D_\delta \mathcal{E}(t, u) \in K^* \} , \]  

\( (57) \)

where \( K^* \) is defined in \( (12) \), the set of points which satisfies the local stability condition typical of BV solutions, \([11, 12] \), it is immediate to check that

\[ \mathcal{S}_D \subseteq \mathcal{S}_D \subseteq \mathcal{S}_\infty \quad \text{for every admissible viscous correction}. \]

The first inclusion is an equality if \( \delta \equiv 0 \). If the energy satisfies the \( \delta \)-convexity property \( (53) \), or, equivalently, if \( \delta \) is chosen big enough, from Proposition 3 we get \( \mathcal{S}_D = \mathcal{S}_\infty \). Figure 4 clarifies the situation with an example.

3.2. **Visco-Energetic Maxwell rule.** After the brief discussion about stability in section 3.1, we now focus on jumps. In this section we show a relation between the minimal sets \( (35) \) and the one-sided global slopes \( W^\prime_{\text{ir}, \delta} \) and \( W^\prime_{\text{sl}, \delta} \), along with some geometrical interpretations of the results.

**Proposition 5.** Let \( t, u \in \mathbb{R} \). Suppose that \( z \in M(t, u) \). Then

\[ W^\prime_{\text{ir}, \delta}(v) \leq \frac{W(z) - W(v)}{z - v} + \frac{\delta(v, z)}{z - v} < \ell(t) - \alpha_+ \quad \text{if} \quad u < v < z, \]  

\( (58) \)

\[ W^\prime_{\text{sl}, \delta}(v) \geq \frac{W(z) - W(v)}{z - v} + \frac{\delta(v, z)}{z - v} > \ell(t) + \alpha_- \quad \text{if} \quad u > v > z. \]  

\( (59) \)

Moreover, if \( u \in \mathcal{S}_D(t) \) the following identities hold:

\[ W^\prime_{\text{ir}, \delta}(u) = \frac{W(z) - W(u)}{z - u} + \frac{\delta(u, z)}{z - u} = \ell(t) - \alpha_+ \quad \text{if} \quad z > u, \]  

\( (60) \)

\[ W^\prime_{\text{sl}, \delta}(u) = \frac{W(z) - W(u)}{z - u} + \frac{\delta(u, z)}{z - u} = \ell(t) + \alpha_- \quad \text{if} \quad z < u. \]  

\( (61) \)
Proof. Let us consider the case \( z > u \). From the minimality of \( z \) for every \( v \in (u, z) \) we get
\[
W(z) - W(v) - \ell(t)(z - v) \leq -\alpha_+(z - v) + \delta(u, v) - \delta(u, z).
\]
Taking (\ref{eq:62}) into account and dividing by \( z - u \) we get
\[
\frac{W(z) - W(v)}{z - v} - \ell(t) < -\alpha_+ - \frac{\delta(u, z)}{z - v},
\]
which proves (\ref{eq:68}). If \( u \in \mathcal{D}(t) \), we can combine the one dimensional D-stability condition (\ref{eq:68}, \ref{eq:58}) with (\ref{eq:68}), where we pass to the limit for \( v \downarrow u \), and we get
\[
W'_{ir,\delta}(u) \leq \frac{W(z) - W(u)}{z - u} + \frac{\delta(u, z)}{z - u} \leq \ell(t) - \alpha_+ \leq W'_{ir,\delta}(u),
\]
so that all the previous inequalities are identities and (\ref{eq:60}) is proved. The case \( z < u \) can be proved in a similar way. \( \square \)

Remark 4. Notice that the strict inequality in (\ref{eq:62}) implies
\[
\begin{align*}
\text{if } z \in M(t, u), z > u, \text{ then } & W'_{ir,\delta}(v) < \ell(t) - \alpha_+ \quad \forall v \in (u, z), \quad (\text{62}) \\
\text{if } z \in M(t, u), z < u, \text{ then } & W'_{ir,\delta}(v) > \ell(t) - \alpha_- \quad \forall v \in (z, u). \quad (\text{63})
\end{align*}
\]
In particular \( v \notin \mathcal{D}(t) \), since (\ref{eq:62}) and (\ref{eq:63}) contradict the global stability (\ref{eq:68}, \ref{eq:68}). This inequalities will be one the key ingredients for the characterization Theorem (\ref{eq:62}).

D-Maxwell rule. Equalities (\ref{eq:60}) and (\ref{eq:61}) admit a nice geometrical interpretation. Suppose that \( u \) is a Visco-Energetic solution, \( t \in J_u \) and that there exists \( z \in M(t, u_k(t)) \) with \( z > u_k(t) \). According to (\ref{eq:56}), \( u_k(t) \) is stable, so that we can choose \( u = u_k(t) \) in (\ref{eq:60}) and we get
\[
W(z) = W(u_k(t)) + (\ell(t) - \alpha_+(z - u_k(t))) - \delta(u_k(t), z). \quad (\text{64})
\]
This identity is a generalization of the so-called Maxwell rule: in the energetic case, combining global stability and energetic balance, we easily get \( z = u_k(t) \), so that (\ref{eq:64}) assume the classical formulation
\[
\int_{u_k(t)}^{u_R(t)} \left( W'(r) - \ell(t) + \alpha_+ \right) dr = 0. \quad (\text{65})
\]
Considering for simplicity the choice \( \delta(u, v) := \frac{\mu}{2} |v - u|^2 \), for some parameter \( \mu > 0 \), when \( W'(u_k(t)) = \ell(t) - \alpha_+ \), (\ref{eq:64}) can be rewritten in the form
\[
W(z) = W(u_k(t)) + W'(u_k(t))(z - u_k(t)) - \frac{\mu}{2} (z - u_k(t))^2.
\]
This means that we can have a jump only when the area between the graph \( W' \) and the straight line whose slope is \(-\mu\) vanishes. If \( \mu \) is big enough, then the area is always positive and \( M(t, u) = \{ u \} \). In this case the description of the jump transition will be more complicated (see section 3.3 and 4 for more details).

3.3. Main characterization Theorem. In this section we exhibit an explicit characterization of Visco-Energetic solutions for a general (i.e. non monotone) external loading \( \ell \). This result is the equivalent of [20, Theorem 3.1] and [20, Theorem 5.1] for Energetic and BV solutions.
\textbf{Theorem 3.2} (1d-characterization of VE solutions). Let $u \in \text{BV}([a,b]; \mathbb{R})$ be a Visco-Energetic solution of the RIveS $(\mathbb{R}, \mathcal{E}, \Psi, \delta)$. Then the following properties hold:

a) $u$ satisfies the 1d-stability condition \([\text{SD,} \mathbb{R}]\) for every $t \in [a,b] \setminus J_u$ (and therefore \((55)\) and \((56)\) as well);

b) $u$ satisfies the following precise formulation of the doubly nonlinear differential inclusion:

\[ W'(u_t(t)) = W'_{a,\delta}(u_t(t)) = \ell(t) - \alpha_+ \quad \text{for every } t \in \text{supp } ((\dot{u})^+) \cap [a,b), \quad (66) \]

\[ W'(u_t(t)) = W'_{a,\delta}(u_t(t)) = \ell(t) + \alpha_- \quad \text{for every } t \in \text{supp } ((\dot{u})^-) \cap [a,b); \quad (67) \]

c) at each point $t \in J_u$, $u$ fulfills the jump conditions

\[ \min(u_t(t), u_R(t)) \leq u(t) \leq \max(u_L(t), u_R(t)) \quad (68) \]

and

\[ W'_{a,\delta}(v) \leq \ell(t) - \alpha_+ \quad \text{if } u_L(t) < u_R(t), \quad W'_{a,\delta}(v) \geq \ell(t) + \alpha_- \quad \text{if } u_L(t) > u_R(t), \quad (69) \]

for every $v$ such that $\min(u_L(t), u_R(t)) \leq v \leq \max(u_L(t), u_R(t))$.

Conversely, let $u \in \text{BV}([a,b], \mathbb{R})$ be a curve satisfying \((66), (67), (68), (69)\), along with the following modified version of a):

a') $u$ satisfies the 1d-stability condition \([\text{SD,} \mathbb{R}]\) for every $t \in (a,b)$.

Then $u$ is a Visco-Energetic solution of the RIveS $(\mathbb{R}, \mathcal{E}, \Psi, \delta)$.

Since any jump point belongs either to the support of $(\dot{u})^+$ or of $(\dot{u})^-$, combining \((66), (68), (69)\) and \((67), (68), (69)\) we also get at every $t \in J_u \cap (a,b)$

\[ W'_{a,\delta}(u_t) = W'_{a,\delta}(u_R) = W'(u_R) = \ell(t) - \alpha_+ \quad \text{if } u_L < u_R, \quad (70) \]

\[ W'_{a,\delta}(u_t) = W'_{a,\delta}(u_L) = W'(u_L) = \ell(t) - \alpha_- \quad \text{if } u_L > u_R, \quad (71) \]

and this identities still hold in $t = a$ or $t = b$ if $u(a) \in S_D(a)$ or $u(b) \in S_D(b)$.

\textbf{Remark 5.} For a full characterization of Visco-Energetic solutions we need that \([\text{SD,} \mathbb{R}]\) holds also when $t \in J_u$. This condition is required just to recover the first
and the second equalities in (J\textsubscript{\textit{VE}}) from the third. However, it is quite natural: if \( u \) is a Visco-Energetic solution, we can consider the right continuous function

\[
\hat{u} \in BV([a, b], \mathbb{R}) \text{ such that } \hat{u}(t) := u_k(t) \text{ for every } t \in [a, b].
\]

Then \( \hat{u} \) is still a Visco-Energetic solution and \( \hat{u}(t) \) is stable for every \( t \in (a, b] \).

**Proof of theorem 3.2.** We split the argument in various steps.

**Claim 1.** D-stability \( (S_D) \) is equivalent to \( (S_{D, R}) \).

It is a consequence of the choice \( \mathcal{E}(t, u) = W(u) - \ell(t)u \); see the discussion in section 3.1.

**Claim 2.** \( (J_{\text{\textit{VE}}} \) implies the jump conditions \( (68) \) and \( (69) \).

From the general properties of the viscous dissipation cost, there exists an optimal transition \( \vartheta \in C(\mathcal{E}; \mathbb{R}) \) connecting \( u_k(t) \) and \( u_\ell(t) \), namely

\[
\vartheta(E^-) = u_k(t), \quad \vartheta(E^+) = u_\ell(t), \quad \mathcal{C}(t, u_k(t), u_\ell(t)) = \text{Trc}(c(t, \vartheta(E)).
\]

Since \( (J_{\text{\textit{VE}}} \) holds, we can apply Theorem 2.9. Let us start from the case \( u_k(t) < u_\ell(t) \) and let \( v \in [u_k(t), u_\ell(t)] \). If \( v \notin \vartheta(E) \), which is compact, there exists an open interval \( I \subset [u_k(t), u_\ell(t)] \setminus \vartheta(E) \) such that \( v \in I \). From (39)

\[
\vartheta(I^+) \in M(t, \vartheta(I^-))
\]

so that, by Proposition 5, we get \( W_{\vartheta, \delta}'(v) \leq \ell(t) - \alpha_+ \). By continuity, the inequality still holds if \( v \in \vartheta(E) \) is isolated in \( \vartheta(E) \cap [v, +\infty) \). Otherwise, \( v \in L(\vartheta(E) \cap [v, +\infty)) \), where \( L \) denotes the set of the limit points. From (39) we have

\[
\mathcal{E}(t, v) \geq \mathcal{E}(t, v_1) + \alpha_+(v_1 - v)
\]

for every \( v_1 \in \vartheta(E) \), \( v_1 > v \), which yields

\[
W_{\vartheta, \delta}'(v) \leq \frac{W(v_1) - W(v)}{v_1 - v} + \frac{\delta(v, v_1)}{v_1 - v} \leq \ell(t) - \alpha_+ + \frac{\delta(v, v_1)}{v_1 - v}.
\]

We can pass to the limit for \( v_1 \downarrow z \) so that (69) holds in \([u_k(t), u_\ell(t)]\). By continuity, it still holds in \( v = u_\ell(t) \). The case \( u_k(t) > u_\ell(t) \) can be proved in a similar way.

The property (68) easily follows by summing the identities of the jump conditions \( (J_{\text{\textit{VE}}} \) thus obtaining

\[
\mathcal{C}(t, u_k(t), u_\ell(t)) = \mathcal{C}(t, u_k(t), u(t)) + \mathcal{C}(t, u(t), u_\ell(t)),
\]

and considering the additivity of the cost (24).

**Claim 3.** The jump conditions \( (68), (69) \) and \( a' \) imply \( (J_{\text{\textit{VE}}} \).

Let us start again with \( u_k(t) < u_\ell(t) \). We still want to apply Theorem 2.9; we need to find an admissible transition \( \vartheta \in C(\mathcal{E}; \mathbb{R}) \) which satisfies (38) and (39). To define such a transition, let us consider

\[
S := \{ v \in [u_k(t), u_\ell(t)] : W_{\vartheta, \delta}'(v) = \ell(t) - \alpha_+ \text{ and } W_{\vartheta, \delta}'(v) \leq \ell(t) + \alpha_- \}
\]

The set \( S \) is compact, then there exists a sequence of disjoint open intervals \( I_k \) such that \( [S^-, S^+] \setminus S = \bigcup_{k=0}^{\infty} I_k \). Let us fix for a moment one of these \( I_k \). Taking into account assumption (48), we can have only two possibilities.

- **Case 1.** “The initial jump”: The infimum in \( W_{\vartheta, \delta}'(I_k^-) \) is attained in a point \( z \geq I_k^- \).

  From \( W_{\vartheta, \delta}'(I_k^-) = \ell(t) - \alpha_+ \) and (60) we recover the energetic balance

  \[
  \mathcal{E}(t, z) + D(I_k^-, z) = \mathcal{E}(t, I_k^-).
  \]
Arguing as in Proposition 5, \( W'_{\ell, \delta}(v) < \ell(t) - \alpha_+ \) for every \( v \in (I_k^-, z) \), so that \( z \in T_k \). We can thus define by induction the sequence \( (u_n^k) \) such that
\[
 u_n^k := z, \quad u_{n+1}^k = u_n^k \quad \text{if} \ u_n^k = I_k^+ \quad u_{n+1}^k \in M(t, u_n^k) \quad \text{otherwise}.
\]
Notice that from Proposition 5 and Remark 4 by induction we easily get \( u_n^k \in T_k \) for every \( n \in \mathbb{N} \). Moreover,
\[
 \Psi(u_{n+1}^k - u_n^k) \leq \mathcal{E}(t, u_n^k) - \mathcal{E}(t, u_{n+1}^k),
\]
so that \( (u_n^k) \) is a Cauchy sequence and then it converges to some \( \bar{u}^k \in T_k \). From the general properties of the residual stability function
\[
 \mathcal{R}(t, u_n^k) = \mathcal{E}(t, u_n^k) - \mathcal{E}(t, u_{n+1}^k) - D(u_n^k, u_{n+1}^k).
\]
By passing to the limit in (74) we get
\[
 \mathcal{R}(t, \bar{u}^k) = 0, \quad \text{so that } \bar{u}^k \in S,
\]
which means \( \bar{u}^k \in \{ I_k^-; I_k^+ \} \). In addition, \( \bar{u}^k \neq I_k^- \) since \( \mathcal{E}(t, u_{n+1}^k) < \mathcal{E}(t, u_n^k) \) every time that \( u_{n+1}^k \neq u_n^k \), which implies \( \mathcal{E}(t, \bar{u}^k) < \mathcal{E}(t, I_k^-) \). Finally, we conclude \( \bar{u}^k = I_k^+ \) and we set \( E_k := \bigcup_{n=0}^{\infty} \{ u_n^k \} \).

- **Case 2. “The (double) chain”**. \( W'(I_k^-) < \frac{W(z)-W(I_k^-_\delta)(I_k^-_\delta)-\delta}{z-I_k^+} \) for every \( z > I_k^- \).

   In this case \( W'_{\ell, \delta}(I_k^-) = W'(I_k^-) = \ell(t) - \alpha_+ \). The energy \( \mathcal{E}(t, u) = W(u) - (W'(I_k^-) + \alpha_+)u \) has negative derivative in \( u = I_k^- \), so that it is decreasing in a neighborhood of \( I_k^- \). Let us choose \( \varepsilon > 0 \) such that \( \mathcal{E}(t, I_k^- + \varepsilon) < \mathcal{E}(t, I_k^-) \). We can thus define by induction the following sequence \( (u_{n, \varepsilon}^k) \):
\[
 u_{n, \varepsilon}^k := I^-_{k} + \varepsilon, \quad u_{n+1, \varepsilon}^k = u_{n, \varepsilon}^k \quad \text{if} \ u_{n, \varepsilon}^k = I_k^+ \quad u_{n+1, \varepsilon}^k \in M(t, u_{n, \varepsilon}^k) \quad \text{otherwise}.
\]
As in the previous case, this sequence is well defined and it converges to \( I_k^+ \). In order to pass to the limit for \( \varepsilon \downarrow 0 \), we apply a compactness argument: we consider the family of sets
\[
 E_{k, \varepsilon} := \bigcup_{n=0}^{\infty} \{ u_{n, \varepsilon}^k \} \cup \{ I_k^+ \}.
\]
\( E_{k, \varepsilon} \) are compact and \( E_{k, \varepsilon} \subseteq T_k \). We can apply Kuratowski Theorem (see e.g. [6]): there exists a compact subset \( E_k \subseteq T_k \) such that, up to a subsequence, \( E_{k, \varepsilon} \to E_k \) in the Hausdorff metric. It is easy to check, [17] Lemma 3.11, that \( E_k^- = I_k^- \), \( E_k^+ = I_k^+ \) and
\[
 z \in M(t, z_{E_k}) \quad \text{for every } z \in E_k,
\]
where \( z_{E_k} \) is defined in [36].

In conclusion, we repeat this construction for every open interval \( I_k \) and we consider \( E := \bigcup_{k=0}^{\infty} E_k \cup S \). Notice that \( E^- = u_k(t) \), \( E^+ = u_k(t) \) and \( E \) is a compact subset of \( \mathbb{R} \). Indeed, \( E \) is bounded and if \( (x_n) \) is a sequence in \( E \) that accumulates in some point \( \bar{x} \), by construction \( x_n \) is definitively contained in one of the sets \( E_k \) or in \( S \), which are compact.

We can thus consider the curve
\[
 \vartheta : E \to \mathbb{R} \quad \text{such that } \vartheta(z) = z \text{ for every } z \in E;
\]
it is an admissible transition connecting \( u_k(t) \) and \( u_k(t) \), with \( \vartheta(E) \ni u(t) \) thanks to \( d' \). It remains just to prove that \( \vartheta \) satisfies [38] and [39].
Concerning (38), for every $I \subset \mathcal{S}(E)$, by construction $\vartheta(I^+) \in M(t, \vartheta(I^-))$, so that

$$\text{Var}_\Psi(\vartheta, E \cap [I^-, I^+]) = \Psi(\vartheta(I^+) - \vartheta(I^-)) \leq \mathcal{E}(t, \vartheta(I^-)) - \mathcal{E}(t, \vartheta(I^+)). \tag{76}$$

When $s \in L^1(\vartheta(E) \cap (-\infty, s])$ we get $\vartheta(s) \in S$, so that $W_{\delta, \nu}(\vartheta(s)) \leq \ell(t) + \alpha_-$. In particular, since $\vartheta$ is increasing

$$\frac{W(\vartheta(r)) - W(\vartheta(s)) + \delta(\vartheta(s), \vartheta(r))}{\vartheta(r) - \vartheta(s)} \leq \ell(t) + \alpha_- \quad \text{for every } r < s.$$ 

After a trivial computation, by using (61) and by passing to the limit we get

$$\limsup_{r \uparrow s} \frac{\mathcal{E}(t, \vartheta(r)) - \mathcal{E}(t, \vartheta(s))}{\text{Var}_\Psi(\vartheta, E \cap [r, s])} \geq 1. \tag{77}$$

We can thus recover (38) from (76) and (77) by using Lemma 2.10, where we set $f(s) := -\mathcal{E}(t, \vartheta(s))$ and $g(s) := \text{Var}_\Psi(\vartheta, E \cap [r, s])$.

Finally, (39) holds with a strict inequality.

Claim 4. \(b)\) is equivalent to the doubly nonlinear equation (DN0).

We notice that (DN0) yields

$$W'(u(t)) = \ell(t) - \alpha_+ \quad \text{for } (\dot{u}_{\text{loc}})^+ \text{-a.e. } t \in (a, b),$$

so that (69) holds by continuity and by (55) in $\text{supp } \dot{u}^+ \setminus J_u$. On the other hand, for every $t \in J_u \cap \text{supp } \dot{u}^+$ we have $u_k(t) < u_k(t)$. From (55) and (69), $\ell(t) - \alpha_+ = W'(u_k(t))$ and then combining Proposition 2.10 and (69) again we get

$$W'(u_k(t)) = W'(u_k(t)) = \ell(t) - \alpha_+,$$

which proves (66). The identities in (67) follow by the same argument.

The converse implication is trivial since $\mu$ is diffuse and therefore $u_k(t) = \mu(t) = u(t)$ for $\mu$-a.e. $t \in (a, b)$. Then (DN0) follows combining (66), (67) and (SD,R).}

The previous general result has a simple consequence: a Visco-Energetic solution is locally constant in a neighborhood of a point where the stability condition (SD,R) holds with a strict inequality.

Corollary 1. Let $u \in \text{BV}([a, b]; \mathbb{R})$ be a Visco-Energetic solution of the RIveS $(\mathbb{R}, \mathcal{E}, \Psi, \delta)$. Then $u$ is locally constant in the open set

$$\mathcal{I} := \{ t \in [a, b] : -\alpha_+ < \ell(t) - W'_{\delta, \nu}(u(t)) \leq \ell(t) - W'_{\nu, \delta}(u(t)) < \alpha_+ \}.$$

Proof. By (69) any $t \in \mathcal{I}$ is a continuity point for $u$; the continuity properties of $W'_{\nu, \delta}(\cdot)$ and $W'_{\delta, \nu}(\cdot)$ then show that a neighborhood of $t$ is also contained in $\mathcal{I}$, so that $\mathcal{I}$ is open and disjoint from $J_u$. Relations (66) and (67) then yield that 

$$\dot{u} = 0 \quad \text{in the sense of distributions in } \mathcal{I},$$

so that $u$ is locally constant.
Example. We conclude this section with the classic example of the double-well potential energy

\[ W(u) = \frac{1}{4}(u^2 - 1)^2. \]

This energy clearly satisfies (48). Notice also that \( W'(u) = u^3 - u \) and \( \min W'' = -1 \). Therefore, if we choose \( \delta(u, v) := (v - u)^2 \), according to Proposition 3, \( W'_{ir, \delta} = W'_{sl, \delta} = W' \) and we expect a similar behaviour to BV solutions, with the optimal transition similar in the form to a “double chain” at every jump point.

If the loading is oscillating, for example \( \ell(t) = \sin(t) \), \( \alpha_\pm = \frac{1}{2} \) and we choose the initial datum such that \( W'(u(a)) = \ell(t) - \alpha_\pm \), the result is a loop typical of the hysteresis phenomena: the solution \( u \) is locally constant when \( \ell \) change direction.

4. Visco-Energetic solutions with monotone loadings. Visco-Energetic solutions of rate-independent systems in \( \mathbb{R} \), driven by monotone loadings, involve the notion of the upper and lower monotone (i.e. nondecreasing) envelopes of the graph of \( W'_{ir, \delta} \) and \( W'_{sl, \delta} \).

In this section we first focus on a few properties of this maps and their inverse and then we exhibit the explicit formulae characterizing Visco-Energetic solutions when \( \ell \) is increasing or decreasing.

4.1. Monotone envelopes of one-sided global slopes.

Definition 4.1 (Upper monotone envelope of \( W'_{ir, \delta} \)). For every \( \bar{u} \) in \( \mathbb{R} \), we define the maximal monotone map \( m^\bar{u}_{ir}(\cdot) : \mathbb{R} \to \mathbb{R} \)

\[ m^\bar{u}_{ir}(u) := \max_{\bar{u} \leq v \leq u} W'_{ir, \delta}(v) \text{ if } u > \bar{u}, \quad m^\bar{u}_{ir}(\bar{u}) := (-\infty, W'_{ir, \delta}(\bar{u})], \]

\[ m^\bar{u}_{ir}(u) = \emptyset \text{ if } u < \bar{u}. \]

(79)
We call $m^\delta_0(\cdot)$ the upper monotone envelope of $W'_{ir,\delta}$ in the interval $(\bar{u}, +\infty)$. The contact set is defined by

$$C^u := \{\bar{u}\} \cup \{u > \bar{u} : W'_{ir,\delta}(u) = m^\delta_0(u)\}.$$  

Thanks to (80), it is easy to check that

$$\lim_{v \to -\infty} W'_{ir,\delta}(v) = -\infty, \quad \lim_{v \to +\infty} W'_{ir,\delta}(v) = +\infty,$$

so that the map $m^\delta_0(\cdot)$ is monotone and surjective; it is also single-valued on $(\bar{u}, +\infty)$ (where we identify the set $m^\delta_0(u)$ with its unique element with a slight abuse of notation). We can thus consider the inverse graph $p^\delta_0(\cdot) : \mathbb{R} \to [\bar{u}, +\infty)$ of $m^\delta_0(\cdot)$: it is defined by

$$u \in p^\delta_0(\ell) \iff \ell \in m^\delta_0(u) \quad \text{for } u, \ell \in \mathbb{R}.$$  

Clearly, $p^\delta_0(\cdot)$ is a maximal monotone graph in $\mathbb{R}$ and it is uniquely characterized by a left-continuous monotone function $p^\delta_{ir,\delta}(\cdot)$ and a right-continuous monotone function $p^\delta_{r,\delta}(\cdot)$ such that

$$p^\delta_{r,\delta}(\ell) = [p^\delta_{ir,\delta}(\ell), p^\delta_0(\ell)] , \quad \text{i.e. } \ell \in m^\delta_0(u) \iff p^\delta_{ir,\delta}(\ell) \leq u \leq p^\delta_{r,\delta}(\ell).$$

We also consider a further selection in the graph of $p^\delta_0(\cdot)$:

$$p^\delta_{i,\delta}(\ell) := \{u \in p^\delta_{ir,\delta}(\ell) : W'_{ir,\delta}(u) = \ell\} = \{u \in C^\bar{u} : m^\delta_0(u) \geq \ell\} = p^\delta_0(\ell) \cap C^\bar{u}. $$

By introducing the set

$$A^\delta_0 := \{f : (\bar{u}, +\infty) \to \mathbb{R} : f \text{ is nondecreasing and fulfills } f \geq W'_{ir,\delta}\},$$

we have

$$m^\delta_0(\cdot)|_{(\bar{u}, +\infty)} \in A^\delta_0, \quad W'_{ir,\delta}(u) \leq m^\delta_0(u) \leq f(u) \text{ for all } f \in A^\delta_0, u \in (\bar{u}, +\infty),$$

so that $m^\delta_0$ is the minimal nondecreasing map above the graph of $W'_{ir,\delta}$ in $(\bar{u}, +\infty)$.

It immediately follows from (81) that

$$m^\delta_0(u) = \inf\{f(u) : f \in A^\delta_0\} \quad \text{for all } u \in (\bar{u}, +\infty).$$

The following result collects some simple properties of $p^\delta_{ir,\delta}(\cdot)$ and $p^\delta_{r,\delta}(\cdot)$.

**Proposition 6.** Assume (80). Then for every $\ell \geq W'_{ir,\delta}(\bar{u})$ there holds

$$W'_{ir,\delta}(u) \leq \ell \quad \text{if } u \in [\bar{u}, p^\delta_{ir,\delta}(\ell)],$$

Moreover, for every $\ell \in \mathbb{R}$ we have

$$p^\delta_{i,\delta}(\ell) = \min\{u \geq \bar{u} : W'_{ir,\delta}(u) \leq \ell\}, \quad p^\delta_{r,\delta}(\ell) = \inf\{u \geq \bar{u} : W'_{ir,\delta}(u) > \ell\}.$$

**Proof.** Property (82) is an immediate consequence of the inequality $W'_{ir,\delta} \leq m^\delta_0(\cdot)$ in $[\bar{u}, +\infty]$.

To prove the first of (83) it is sufficient to notice that

$$W'_{ir,\delta}(u) \leq m^\delta_0(u) < \ell \quad \text{if } \bar{u} \leq u < p^\delta_{ir,\delta}(\ell),$$

and $m^\delta_0(u) = \ell$ if $u = p^\delta_{ir,\delta}(\ell)$. For the second of (83), we observe that, when $u > p^\delta_{ir,\delta}(\ell)$ we have $m^\delta_0(u) > \ell$, and we know that there exists $v \in [p^\delta_{r,\delta}(\ell), u]$ such that $W'_{ir,\delta}(v) > \ell$. Since $u$ is arbitrary we get

$$p^\delta_{r,\delta}(\ell) \geq \inf\{u \geq \bar{u} : W'_{ir,\delta}(u) > \ell\}.$$

The converse inequality follows from (82).

In a completely similar way we can introduce the maximal monotone map below the graph of $W'_{ir,\delta}$ on the interval $(-\infty, \bar{u}]$. 

Definition 4.2 (Lower monotone envelope of $W_{a,b}^r$). For every $\bar{u} \in \mathbb{R}$, we define the maximal monotone map $n_\bar{u}^a : \mathbb{R} \to \mathbb{R}$

$$n_\bar{u}^a(u) := \inf_{\bar{u} \leq v \leq u} W_{a,b}^r(v) \quad \text{if} \; u < \bar{u}, \quad n_\bar{u}^a(\bar{u}) := \begin{cases} W_{a,b}^r(\bar{u}), & +\infty \end{cases},$$

$$n_\bar{u}^a(u) = \emptyset \quad \text{if} \; u > \bar{u},$$ (84)

Which satisfies

$$n_\bar{u}^a(u) = \sup\{f(u) : f \in B_{\bar{u}}^a\} \quad \text{for} \; u < \bar{u},$$

where

$$B_{\bar{u}}^a := \{f : (-\infty, \bar{u}) \to \mathbb{R} : f \text{ is nondecreasing and fulfills } f \leq W_{a,b}^r\}.$$

As before, the inverse graph $q_\bar{u}^a(\cdot) := (n_\bar{u}^a(\cdot))^{-1} : \mathbb{R} \to (-\infty, \bar{u}]$ can be represented as $q_\bar{u}^a(u) = \left[q^{\bar{u}}_u(u), q_{\bar{u},a}^u(u)\right]$, where

$$q^{\bar{u}}_u(u) = \sup\{u \leq \bar{u} : W_{a,b}^r(u) < \ell\}, \quad q_{\bar{u},a}^u(u) = \max\{u \leq \bar{u} : W_{a,b}^r(u) \leq \ell\}$$

and we set

$$q_{\ell,a}^\bar{u}(\ell) := \{u \in q_\bar{u}^a(\ell) : W_{a,b}^r(u) = \ell\}.$$

4.2. Monotone loadings and Visco-Energetic solutions. We apply the notions introduced in the previous section to characterize Visco-Energetic solutions when $\ell$ is monotone. First of all, we provide an explicit formula yielding Visco-Energetic solutions for an increasing loading $\ell$. The case of a decreasing and of a piecewise monotone loading can be proved in a similar way.

Theorem 4.3. Let $\bar{u} \in \mathbb{R}, \ell \in C^1([a, b])$ be a nondecreasing loading such that

$$\ell(a) \geq W_{a,b}^r(\bar{u}) - \alpha_-. \quad (85)$$

Any nondecreasing map $u : [a, b] \to \mathbb{R}$, with $u(a) = \bar{u}$, such that for every $t \in (a, b]$

$$W_{a,b}^r(u(t)) - \alpha_- \leq W^r(u(t)), \quad u(t) \in p_{\ell,a}^\bar{u} (\ell(t) - \alpha_+ - t)$$ (86)

is a Visco-Energetic solution of the RIveS $(\mathbb{R}, \mathcal{E}, \Psi, \delta)$. In particular, \[ yields

$$u(t) \in [p_{\ell,a}^{\bar{u}}(\ell(t) - \alpha_+) \cup p_{\ell,a}^{\bar{u}}(\ell(t) - \alpha_+)] \quad \text{for every} \; t \in (a, b].$$ (87)

Proof. We apply Theorem 3.2. Concerning the global stability condition, notice that \[ yield

$$W_{t,a}^r(u(t)) = W^r(u(t)) \quad \text{for every} \; t \in (a, b].$$ (88)

Indeed, if $W_{t,a}^r(u(t)) \neq W^r(u(t))$, from Proposition 4, $W_{t,a}^r$ is decreasing in a neighborhood of $u(t)$, which contradicts the second of \[. Therefore, the first of \[, combined with \[ gives \[ for every $t \in (a, b]$.

To check the equation \[, we set

$$\gamma := \inf\{t > a : u(t) > u(a)\}.$$ If $W_{t,a}^r(u(a)) < \ell(a) - \alpha_+$, then from \[ $a \in J_u$ and $W_{t,a}^r(u(a)) = \ell(a) - \alpha_+$. Otherwise, $u(a)$ satisfies the stability condition and $u$ is clearly a constant Visco-Energetic solution on $[a, \gamma]$. Thus, it is not restrictive to assume that $\gamma = a$ by Proposition 2. In this case $u(t) > u(a)$ for every $t > a$ and by continuity \[ yields

$$W_{t,a}^r(u(t)) = W_{a,b}^r(u(t)) = \ell(t) - \alpha_+ \quad \text{for every} \; t \in (a, b),$$ (89)

and the second identity still holds in $t = a$. Thus, from the first of \[ and the continuity of $W$ we finally get \[.

Theorem 4.4. Let \( \overline{u} \in \mathbb{R} \) and \( \ell \in C^1([a,b]) \) be a nonincreasing loading such that
\[
\ell(a) \leq W'_{\overline{u},\delta}(\overline{u}) + \alpha_.
\] (91)
Any nonincreasing map \( u : [a,b] \to \mathbb{R} \), with \( u(a) = \overline{u} \), such that
\[
W'_{\overline{u},\delta}(u(t)) + \alpha_+ \geq W'(u(t)), \quad u(t) \in q_{\delta}(\ell(t) + \alpha_) \text{ for every } t \in (a,b)
\] (92)
is a Visco-Energetic solution of the RIveS \((\mathbb{R}, \mathcal{E}, \Psi, \delta)\). In particular, \( u \) satisfies the \( \delta \)-convexity assumption (53). In this case
\[
W'_{\overline{u},\delta}(u) = W'(u) = W'_{\overline{u},\delta}(u) \quad \text{for every } u \in \mathbb{R}.
\] (93)

Remark 6. The first condition of \( W'_{\overline{u},\delta}(u) \) (resp. the first of \( (92) \)) holds if the energy density \( W \) satisfies the \( \delta \)-convexity assumption (53). In this case
\[
W'_{\overline{u},\delta}(u) = \ell(a) - \alpha_.
\] (94)
In particular, it is satisfied if \( W \) is \( \lambda \)-convex, see (54), and we choose a quadratic \( \delta \), tuned by a parameter \( \mu \geq \min\{-\lambda, 0\} \).

The next result shows that, under a slightly stronger condition on the initial data, any Visco-Energetic solution driven by an increasing loading admits a similar representation to (86); the second inclusion holds for every \( t \not\in J_u \).

Theorem 4.5 (Nondecreasing loading). Let \( \ell \in C^1([a,b]) \) be a nondecreasing loading and let \( u \in BV([a,b], \mathbb{R}) \) be a Visco-Energetic solution of the RIveS \((\mathbb{R}, \mathcal{E}, \Psi, \delta)\) satisfying
\[
\ell(a) \geq W'_{\overline{u},\delta}(u(a)) - \alpha_-, \quad \text{IC1}
\]
\[
W' < W'(u(a)) \text{ in a left neighborhood of } u(a) \quad \text{if } W'(u(a)) = \ell(a) + \alpha_-. \quad \text{IC2}
\]
and for every \( z < u(a) \),
\[
\frac{W(z) - W(u(a)) + \delta(\ell(u(a)), z)}{z - u(a)} < W'_{\overline{u},\delta}(u(a)) \quad \text{if } W'_{\overline{u},\delta}(u(a)) = \ell(a) + \alpha_-. \quad \text{IC3}
\]
Then, similarly to Theorem 4.3, \( u \) satisfies
\[
u(t) \in P_{\ell,\delta}(\ell(t) - \alpha_+) \quad \text{for every } t \in [a,b] \setminus J_u \quad (94)
\]
and therefore
\[
u(t) \in [p_{\ell,\delta}(\ell(t) - \alpha_+), p_{\ell,\delta}(\ell(t) - \alpha_+)] \quad \text{for every } t \in [a,b]. \quad (95)
\]
This result is a generalization to the visco-energetic framework of [20, Theorem 6.3]. One of the technical point there is to avoid the extra assumption

\[ W_{\delta}(u) - \alpha_- \leq \ell(t) < W'_{\rho}(u) + \alpha_+ \quad \text{for every } u \in \mathbb{R}, \tag{96} \]

which is not immediately satisfied if \( \alpha_{\pm} \) are very small. In our context, if \( \delta \) is too small \[96\] is still not satisfied even if we replace the one-sided slopes with their \( \delta \)-corrected versions.

The next technical lemma contributes to solve this issue. Compared with the same result in the energetic setting, we need a more refined analysis of the behaviour of \( u \) at jumps.

**Lemma 4.6.** Under the same assumptions of Theorem 4.5 let \( a < \sigma' < \sigma \leq b \) be such that

\[ \ell(t) - W'(u_R(t)) > -\alpha_- = \ell(\sigma) - W'(u_R(\sigma)) \quad \text{for every } t \in [\sigma', \sigma). \tag{97} \]

Then \( \sigma \notin J_u \).

**Proof.** We argue by contradiction and assume that \( \sigma \in J_u \). In view of \[66\] necessarily

\[ u_k(\sigma) > u_R(\sigma), \tag{98} \]

and \[67\] shows that \( u_R \) is nondecreasing in \([\sigma', \sigma)\). Moreover, combining \[56\] and \[69\],

\[ \ell(\sigma) + \alpha_- = W_{\delta, \delta}'(u_k(\sigma)) > W'(u_k(\sigma)), \]

so that by Proposition 4 there exists \( \hat{u} < u_k(\sigma) \) which attains the supremum in the definition of \( W_{\delta, \delta}'(u_k(\sigma)) \) and a neighborhood of \( u_k(\sigma) \) in which \( W_{\delta, \delta}'(u) \) is decreasing.

We want to prove that \( u_k(\sigma) = u(a) \). We consider the set

\[ P := \{ \rho \in [a, \sigma) : u_R(t) \equiv u_k(\sigma), \ \ell(t) = \ell(\sigma) \quad \text{for all } t \in [\rho, \sigma) \}, \]

and we prove that \([a, \sigma) = P\).

**Claim 1.** \( P \neq \emptyset \) and \( P \) is closed in \([a, \sigma)\).

We need to show that \( \ell \) and \( u \) are constant in a left neighborhood of \( \sigma \). We already know that they are nondecreasing in \([\sigma', \sigma)\). To show that they are also nonincreasing we argue by contradiction: assume that there exists a sequence \( t_n < \sigma \) converging to \( \sigma \) such that

\[ u_n := u_R(t_n) \uparrow u_k(\sigma), \ \ell_n := \ell(t_n) \uparrow \ell(\sigma) \quad \text{and} \quad u_n + \ell_n < u_k(\sigma) + \ell(\sigma). \]

Then, for \( n \) great enough, \( u_n > \hat{u} \). If \( u_n < u_k(\sigma) \) the global stability \[55\] and the jump condition \[63\] yield

\[ \ell_n + \alpha_- \geq W_{\delta, \delta}'(u_n) > \ell(\sigma) + \alpha_- \geq \ell_n + \alpha_- , \]

which is absurd. Similarly, if \( \ell_n < \ell(\sigma) \),

\[ \ell_n + \alpha_- \geq W_{\delta, \delta}'(u_n) \geq \ell(\sigma) + \alpha_- > \ell_n + \alpha_- . \]

This proves that \( P \) contains a left neighborhood of \( \sigma \) and then it is non-empty. Moreover, \( P \) is clearly closed in \([a, \sigma)\).

**Claim 2.** Suppose that \( \rho \in P \). Then \( \rho \notin J_u \).

By contradiction suppose that \( \rho \in J_u \). From Proposition 4 \( W'_{\rho} \) is decreasing in an open set containing \( u_k(\sigma) = u_R(\rho) \). From \[69\] the only possibility is that \( u_k(\rho) < u_k(\rho) \).
Suppose that $u_k(\rho) \leq u_k(\sigma)$. Then we consider an optimal transition $\vartheta \in C(E, \mathbb{R})$ connecting $u_k(\rho)$ and $u_k(\rho)$. Clearly, $u_k(\sigma) \notin E$ since $E(\rho, u_k(\sigma)) = E(\sigma, u_k(\sigma))$ but from $(J \vee E)\gamma$ the energy is decreasing during a transition:

$$E(\sigma, u_k(\sigma)) < E(\sigma, u_k(\sigma)) = E(\rho, u_k(\rho)) < E(\rho, u_k(\sigma)).$$

Then $u_R(\sigma)$ must be in a hole of $E$. Combining Theorem 2.9 and Proposition 5, $W_{\alpha,\delta}'(u_k(\sigma)) < \ell(\sigma) - \alpha_+$, which contradicts the global stability (55). In a similar way we can discuss the case $u_k(\rho) \geq u_k(\sigma)$.

**Claim 3.** If $a < \rho \in P$, there exists $\varepsilon > 0$ such that $\ell(t) = \ell(\rho) = \ell(\sigma)$ and $u(t) = u(\rho) = u(\sigma)$ for every $t \in [\rho - \varepsilon, \rho]$.

Thanks to Claim 2, $\rho \notin J_u$. Then we can argue as in Claim 1, starting from $u_k(\rho) = u(\sigma)$ and $\ell(\rho) = \ell(\sigma)$.

**Conclusion.** $P$ is also open in $[a, \sigma)$ since for every $\rho \in P \cap (a, \sigma)$, it contains a left neighborhood of $\rho$ ($P$ obviously contains also a right neighborhood of $\rho$). Since $P$ is both open and closed, $P = [a, \sigma)$.

Another application of Claim 2, combined with (IC3), which prevents the case $u(a) > u_k(a)$, yields that $a \notin J_u$, so that $u_k(\sigma) = u(a)$ and $\ell(\sigma) = \ell(a)$. Finally, another application of (IC3), gives the contradiction with (98).

With these notions at our disposal, the proof of Theorem 4.5 is a simple adaptation of [20] Theorem 6.3]. For completeness, we report the steps in details.

**Proof of Theorem 4.5.** We split again the argument in various steps.

**Claim 1.** There exists $\gamma \in [a, b]$ such that $\ell(t) - W'(u_k(r)) > \gamma$ for all $t \in (\gamma, b]$ and $u(t) = u(a)$, $\ell(t) = \ell(a)$ in $[a, \gamma]$.

Let us consider the set

$$\Sigma := \{ t \in [a, b] : W'(u_k(t)) = \ell(t) + \alpha_- \}$$

and observe that $t_n \in \Sigma$, $t_n \downarrow t$ $\Rightarrow$ $t \in \Sigma$. If $a \in \Sigma$, we denote by $\Sigma_a$ the connected component of $\Sigma$ containing $a$ and we set $\gamma := \sup \Sigma_a$. If $\gamma > a$, then

$$W'(u_k(t)) = \ell(t) + \alpha_- \text{ for every } t \in [a, \gamma],$$

so that by (66) $u$ is nonincreasing in $[a, \gamma]$. Assumption (IC3) imply that $a \notin J_u$ and $u_k(a) = u(a)$. Since also $\ell$ is nondecreasing we conclude by (IC2) and (67) that $u(t) \equiv u(a)$ and $\ell(t) \equiv \ell(a)$ in $[a, \gamma]$; moreover, by the same argument, $\gamma \notin J_u$, so that $\gamma \in \Sigma$. When $a \notin \Sigma$ we simply set $\gamma := a$ and $\Sigma_a = \emptyset$.

The claim then follows if we show that $\Sigma \setminus \Sigma_a$ is empty. This is trivial if $\gamma = b$. If $\gamma < b$ we suppose $\Sigma \setminus \Sigma_a \neq \emptyset$ and we argue by contradiction. We can find points $\gamma_2 > \gamma_1 > \gamma$ such that $\gamma_1 \notin \Sigma$ and $\gamma_2 \in \Sigma$. We can consider $\sigma := \min(\Sigma \cap [\gamma_1, b]) > \gamma_1 > \gamma$. Lemma 4.6 with $\gamma' := \gamma_1$ yields that $\sigma \notin J_u$, so that we can find $\varepsilon > 0$ such that

$$-\alpha_- < \ell(t) - W'(u_k(t)) < \alpha_+ \text{ for every } t \in (\sigma - \varepsilon, \sigma).$$

(99)

Point $b$ of Theorem 3.2 implies that $u_k(t) = u(t) \equiv u(\sigma) = u_k(\sigma)$ is constant in $(\sigma - \varepsilon, \sigma)$. Hence, $W'(u_k(t)) \equiv W'(u_k(\sigma)) = \ell(\sigma) + \delta_- \geq \ell(t) + \delta_-$ for every $t \in (\sigma - \varepsilon, \sigma)$, since $\ell$ is nondecreasing and $\sigma \in \Sigma$. This contradicts (99).

**Claim 2.** $u$ is nondecreasing in $[a, b]$. 

satisfying in \((\text{Nonincreasing loading})\) Theorem 4.7 solutions in the case of a decreasing load.

Claim 3. Let \(B := \{t \in [\gamma, b] : W'_{\alpha, \delta}(u(a)) + \alpha_+ = \ell(t)\}\) and let \(\beta := \min B\) (with the convention \(\beta = b\) if \(B\) is empty). Then \(u(t) \equiv u(a)\) in \([a, \beta)\) and

\[W'_{\alpha, \delta}(u(t)) = W'_{\beta, \delta}(u(t)) = \ell(t) - \alpha_+ \quad \text{for all } t \in (\beta, b). \quad (100)\]

In particular, \(u(t) \geq p^{u(a)}_{\alpha, \delta}(\ell(t) - \alpha_+)\) for all \(t \in [a, b]\).

The first statement follows from the previous Claim and Corollary 1.

To prove the second identity in (100), we argue by contradiction and we suppose that exists a point \(s \in (\beta, b)\) such that \(W'_{\alpha, \delta}(u(s)) + \alpha_+ > \ell(s)\). Then, in view of Corollary 1, \(u\) is locally constant around \(s\). Since \(\ell\) is nondecreasing, because of (66), we conclude that \(u(t) \equiv u(s)\) for every \(t \in [\gamma, s]\), so that \(s \leq \beta\), a contradiction. The first identity of (100) follows by continuity and by (66).

The last statement is a consequence of (83). Notice that we can also take \(t = b\) since \(W'_{\alpha, \delta}(u(t)) = \ell(t) - \alpha_+\) still holds in \(t = b\).

Claim 4. For all \(t \in [a, b]\) we have \(u(t) \leq p^{u(a)}_{\alpha, \delta}(\ell(t) - \alpha_+)\).

If \(u(t) = u(a)\) there is nothing to prove. Otherwise, let \(t \geq \beta\) and take \(z \in (u(a), u(t))\). Since \(u\) is nondecreasing, there exists \(s \in [\beta, t]\) such that \(u(s) \leq z < u(t)\), so that (69) (in the case \(s \in J_a\)) or (66) (in the case \(u(s) = u(t)\)) yield

\[W'_{\alpha, \delta}(z) \leq \ell(s) - \alpha_+ \leq \ell(t) - \alpha_+,
\]

since \(\ell\) is nondecreasing. Being \(z < u(t)\) arbitrary, the claim follows from the second of (83).

Conclusion. Combining Claim 2, Claim 3 and Claim 4, we get

\[p^{u(a)}_{\alpha, \delta}(\ell(t) - \alpha_+) \leq u(t) \leq u(t) \leq p^{u(a)}_{\alpha, \delta}(\ell(t) - \alpha_+) \quad \text{for all } t \in [a, b],\]

which proves relation (95). Finally, (94) is due to (95) and (100). \(\square\)

In a similar way, we can deduce the characterization of Visco-Energetic solutions in the case of a decreasing load.

Theorem 4.7 (Nonincreasing loading). Let \(\ell \in C^1([a, b])\) be a nonincreasing loading and let \(u \in BV([a, b], \mathbb{R})\) be a Visco-Energetic solution of the RIveS \((\mathbb{R}, \mathcal{E}, \Psi, \delta)\) satisfying

\[\ell(a) \leq W'_{\alpha, \delta}(u(a)) + \alpha_+, \quad (101)\]

\[W' > W'(u(a)) \quad \text{in a right neighborhood of } u(a)\] if \(W'(u(a)) = \ell(a) - \alpha_+; \quad (102)\]

and, for every \(z > u(a)\),

\[\frac{W(z) - W(u(a)) + \delta(u(a), z)}{z - u(a)} > W'_{\alpha, \delta}(u(a)) \quad \text{if } W'_{\alpha, \delta}(u(a)) = \ell(a) - \alpha_+. \quad (103)\]

Then, similarly to Theorem 4.4 \(u\) satisfies

\[u\ \text{is nonincreasing, } u(t) \in q^{u(a)}_{\alpha, \delta}(\ell(t) + \alpha_-) \quad \text{for every } t \in [a, b] \setminus J_u \quad (104)\]

and therefore

\[u(t) \in [q^{u(a)}_{\alpha, \delta}(\ell(t) + \alpha_-), q^{u(a)}_{\alpha, \delta}(\ell(t) + \alpha_-)] \quad \text{for every } t \in [a, b]. \quad (105)\]
Example. We conclude with a final example, involving a more complex potential $W$ (see figure 7). When $W \in C^2([a,b]; \mathbb{R})$ and we choose $\delta(u,v) := \frac{\mu}{2} (v-u)^2$, with $\mu \geq -\min W''$, Visco-Energetic solutions follow the monotone envelope of $W' + \alpha_+$.

Figure 7. Visco-Energetic solutions of a nonconvex energy and an increasing loading. The optimal transition is a combination of sliding and viscous parts.
