Soft, collinear and non-relativistic modes in radiative decays of very heavy quarkonium

Xavier Garcia i Tormo and Joan Soto

Departament d’Estructura i Constituents de la Matèria, Universitat de Barcelona
Diagonal 647, E-08028 Barcelona, Catalonia, Spain

We analyze the end-point region of the photon spectrum in semi-inclusive radiative decays of very heavy quarkonium ($m_{\alpha}^2 \gg \Lambda_{QCD}$). We discuss the interplay of the scales arising in the Soft-Collinear Effective Theory, $m, m(1-z)^{1/2}$ and $m(1-z)$ for $z$ close to 1, with the scales of heavy quarkonium systems in the weak coupling regime, $m, m_0$, and $m_0^2$. For $1-z \sim \alpha_s^2$ only collinear and (ultra)soft modes are seen to be relevant, but the recently discovered soft-collinear modes show up for $1-z \ll \alpha_s^2$. The S- and P-wave octet shape functions are calculated. When they are included in the analysis of the photon spectrum of the $\Upsilon(1S)$ system, the agreement with data in the end-point region becomes excellent. The NRQCD matrix elements $\langle 1^3S_1|O_6(1^{S_0})|1^3S_1 \rangle$ and $\langle 1^3S_1|O_8(3P_3)|1^3S_1 \rangle$ are also obtained.

I. INTRODUCTION

Effective field theories (EFT) have proved extremely useful in the field of strong interactions. Applications to high energy processes in QCD involving very energetic partons \cite{1}, however, have been elusive until recently. Important features of a suitable EFT for such processes were outlined in \cite{2}, which led to the development of the so called Soft-Collinear Effective Theory (SCET) \cite{3,4,5} (see \cite{6} for a pedagogical introduction).

SCET has generated high expectations. Indeed factorization proofs appear to greatly simplify and power corrections seem to become under control. In addition, a large number of potential applications is envisaged \cite{7}. Among those, exclusive and semi-inclusive $B$-decays have deserved special attention due to the necessity to have a good control on the hadronic effects in order to extract the CKM matrix elements from the abundant $B$-factory data.

SCET was originally formulated in terms of soft, collinear and usoft modes. Later, it was realized that two possible scalings for collinear modes were relevant and the terminology SCET\textsubscript{I} and SCET\textsubscript{II} was introduced. Recently a new mode, called soft-collinear, has been claimed to be necessary \cite{8} (see \cite{9} for the latest discussions). It is often assumed that some of the momentum components of these modes have typical sizes $\sim \Lambda_{QCD}$ or even smaller.

One of the difficulties that one faces in $B$-physics is that the bound state dynamics of the initial $B$-meson is dominated by the scale $\Lambda_{QCD}$, and hence a weak coupling analysis is not reliable. Therefore, the interplay of the initial bound state dynamics with final state modes of momentum components of the order $\Lambda_{QCD}$ (or smaller) is difficult to figure out. We advocate here that a very heavy quarkonium in the initial state may provide an excellent theoretical tool to shed light on this issue, since the bound state dynamics occurs at weak coupling and it is amenable of a detailed analysis. We shall illustrate this point by analyzing the end-point region of the photon spectrum in inclusive decays of very heavy quarkonium.

Semi-inclusive radiative decays for the $\Upsilon(1S)$ have already been discussed in the framework of SCET \cite{9,10,11}. SCET has been used to put forward factorization formulas and to resum Sudakov logarithms. An improved description of data \cite{12} with respect to earlier approaches \cite{13} has been achieved. However, the bound state dynamics, which is relevant for the evaluation of the octet shape functions, has not been studied in detail, but rather modeled by analogy with $B$-meson systems \cite{14}, which is a doubtful approximation. We shall calculate here the octet shape functions under the assumption that the bottom quark is sufficiently heavy as to consider $\Upsilon(1S)$ a Coulombic state. This assumption appears to be self-consistent in the calculation of the spectrum \cite{15,16,17,18}, and decay and production currents \cite{19}. We observe that the factorization scale dependence of the shape functions is sensible to the bound state dynamics and discuss its cancellation.

We distribute the paper as follows. In section \textbf{II} we calculate the photon spectrum at the end-point region in the weak coupling regime. We do so by matching first QCD to Non-Relativistic QCD (NRQCD) \cite{20} +SCET\textsubscript{I}, next NRQCD+SCET\textsubscript{I} to Potential NRQCD (pNRQCD) \cite{21} +SCET\textsubscript{II}, and finally carrying out the calculations in the later

EFT. We confirm the factorization formulas \[10\] \[11\] and obtain the octet shape functions. In section \[11\] we apply our results to the \(\Upsilon(1S)\) system and obtain a very good description of the experimental data \[12\] in the end-point region. In section \[14\] we discuss the interplay of the several scales in the problem, in particular the emergence of a soft-collinear region. In section \[15\] is devoted to the conclusions. In the Appendix we present results for NRQCD octet matrix elements of the \(1^3S_1\) state, which follow from those of section \[11\].

II. THE END-POINT REGION OF THE PHOTON SPECTRUM

We start from the formula given in Ref. \[11\]

\[
\frac{d\Gamma}{dz} = z \frac{M}{16\pi^2} \text{Im} T(z) \quad T(z) = -i \int d^4x e^{-iq\cdot x} \langle n^{2S+1}L,J|T(J_\mu(x)J_\nu(0))|n^{2S+1}L,J\rangle \eta^\mu_1^\nu (1)
\]

where \(J_\mu(x)\) is the electromagnetic current for heavy quarks in QCD and we have used spectroscopic notation for the heavy quarkonium states. The formula above holds for states fulfilling relativistic normalization. In the case where \(n = (n_+, n_-, n_\perp) = (1, 0, 0)\) and \(P_\perp = \epsilon_{\alpha\beta\gamma}\partial^n\). These effective currents can be identified with the leading order in \(\alpha_s\) of the currents introduced in \[11\]. We use both Latin (1 to 3) and Greek (0 to 3) indices, \(B_\perp\) is a single collinear

---

1 One loop matching calculations are already available analytical for the octet currents \[22\] and numerical for the singlet one \[24\].
the SCET side, the restriction above implies that one may also restrict collinear gluons in the final state to have $S \lesssim f$ further in the EFT hierarchy. As discussed in Ref. [21], NRQCD still contains quarks and gluons with energies pseudoscalar components, namely $B$, integrated out [9]. The integration of this scale produces the dominant contributions from the color singlet currents.

If we restrict ourselves to $(1,3,8,0,3,3)$, the scale of the binding energy, we can proceed one step further in the EFT hierarchy. As discussed in Ref. [21], NRQCD still contains quarks and gluons with energies $\sim m_{Q_s}$, which, in the situation above, can be integrated out. This leads to Potential NRQCD (pNRQCD). On the SCET side, the restriction above implies that one may also restrict collinear gluons in the final state to have $r_+ , r_\perp \ll M \sqrt{1 - z} \lesssim m_{Q_s}$, as we shall do. The scale $M \sqrt{1 - z}$, which is still active in SCET$_{1}$, must then be integrated out [4]. The integration of this scale produces the dominant contributions from the color singlet currents. We have

$$\left\langle 3 S_1 | T \{ J^{\alpha \beta}_{(1,3,8,0,3,3)}(x) J^{\alpha' \beta'}_{(1,3,8,0,3,3)}(0) \} | 3 S_1 \right\rangle \rightarrow$$

$$\rightarrow 2 N_c S_{V}^{i}(x,0,0) S_{V}^{i}(0,0,0) \left\langle \text{VAC} | Tr \{ B_{i}^{\alpha} B_{i}^{\alpha} \} (x) Tr \{ B_{i}^{\alpha} B_{i}^{\alpha} \} (0) \text{VAC} \right\rangle$$

The calculation of the vacuum correlator for collinear gluons above has been carried out in [11], and the final result, which is obtained by sandwiching [7] between the quarkonium states, reduces to the one put forward in that reference.

For the color octet currents, the leading contribution arises from a tree level matching of the currents [2],

$$J^{\alpha}_{(8,1,8,0,0,3,3)}(x) \rightarrow 2 T_F O_{P}^{\alpha}(x,0,0) B_{i}^{\alpha}(x)$$

$$J^{\alpha \beta}_{(8,3,3,3,3,3)}(x) \rightarrow 2 T_F \left( i \nabla_{y} O_{V}^{\alpha}(x,y,0) \right) \bigg|_{y=0} B_{i}^{\alpha} (x)$$

$S_{V}^{i}$, $O_{P}^{\alpha}$ and $O_{V}^{\alpha}$ are the projection of the singlet and octet field strengths introduced in [21] to their vector and pseudoscalar components, namely $S = (S_P + S_V ^{i} \sigma^i) / \sqrt{2}$ and $O^{\alpha} = (O_{P}^{\alpha} + O_{V}^{\alpha} \sigma^i) / \sqrt{2}$. $T_F = 1/2$ and $N_c = 3$ is the number of colors. $B_{i}^{\alpha}(x)$ in (8) are now collinear gluons with $r_+ , r_\perp \ll M \sqrt{1 - z} \lesssim m_{Q_s}$.
FIG. 1: Color octet contributions. ● represents the color octet S-wave current, ▲ represents the color octet P-wave current. The notation for the other vertices is that of Ref. 22, namely \( \Phi := -\frac{ie_p}{\sqrt{N_c}T_F} \frac{[\sigma_1 \cdot \sigma_2]}{2\pi} \text{Tr} \left[ T^aB \right] \) and \( \Theta := -\frac{ie}{\sqrt{N_c}T_F} \text{Tr} \left[ T^aE \right] \). The solid line represents the singlet field, the double line represents the octet field and the gluon with a line inside represents a collinear gluon.

C. Calculation in pNRQCD+SCETII

We shall then calculate the contributions of the color octet currents in pNRQCD coupled to collinear gluons. They are depicted in Fig. 1. For the contribution of the P-wave current, it is enough to have the pNRQCD Lagrangian at leading (non-trivial) order in the multipole expansion given in 21. For the contribution of the S-wave current, one needs a \( 1/m \) chromomagnetic term given in 23.

Let us consider the contribution of the S-wave color octet current in some detail. We have from the first diagram of Fig. 1

\[
T_{(\tilde{s}, \tilde{s}_0)}^{\alpha \alpha'}(z) = -i\eta_\perp^{\alpha\alpha'}(4\pi) \frac{32}{3} T_F^2 \left( \frac{c_F}{2m} \right)^2 \alpha_s(\mu_u) C_F \int d^3\mathbf{x} \int d^3\mathbf{x}' \psi_{\tilde{n}0}(\mathbf{x}') \psi_{\tilde{n}0}(\mathbf{x}) \int \frac{dk_2}{(2\pi)^4} \frac{k_2^2}{k_2^2 + i\epsilon} \times
\]

\[
x \times \left( \frac{1}{-k_0 + E_n - \hbar_o + i\epsilon} \right)_{\mathbf{x}', 0} \frac{1}{(M(1 - z) - k_0 + k_2)\mu} \frac{1}{M - k_2 + i\epsilon} \left( \frac{1}{-k_0 + E_n - \hbar_o + i\epsilon} \right)_{0, \mathbf{x}}
\]

where we have used the Coulomb gauge (both for ultrasoft and collinear gluons). \( E_n < 0 \) is the binding energy \( (M = 2m + E_n) \) of the heavy quarkonium, \( \psi_{\tilde{n}0}(\mathbf{x}) \) its wave function, and \( \hbar_o \) the color-octet Hamiltonian at leading order, which contains the kinetic term and a repulsive Coulomb potential 21. \( c_F \) is the hard matching coefficient of the chromomagnetic interaction in NRQCD 20, which will eventually be taken to 1. We have also enforced that \( k_2 \) is ultrasoft by neglecting it in front of \( M \) in the collinear gluon propagator. We shall evaluate 20 in light cone coordinates. If we carry out first the integration over \( k_2 \), only the pole \( k_2 = k_2^2/k_+ \) contributes. Then the only remaining singularities in the integrand are in the collinear gluon propagator. Hence, the absorptive piece can only come from its pole \( M^2(1 - z) - M k_+ = k_+^2 \). If \( k_+ \lesssim M(1 - z) \), then \( k_+^2 \sim M^2(1 - z) \) which implies \( k_+ \sim M \). This contradicts the assumption that \( k_2 \) is ultrasoft. Hence, \( k_+^2 \) must be expanded in the collinear gluon propagator. We then have

\[
\text{Im} \left( T_{(\tilde{s}, \tilde{s}_0)}^{\alpha \alpha'}(z) \right) = -\eta_\perp^{\alpha\alpha'}(4\pi) \frac{32}{3} T_F^2 \left( \frac{c_F}{2m} \right)^2 \alpha_s(\mu_u) C_F \times
\]

\[
x \times \int d^3\mathbf{x} \int d^3\mathbf{x}' \psi_{\tilde{n}0}(\mathbf{x}') \psi_{\tilde{n}0}(\mathbf{x}) \frac{1}{8\pi M} \int_0^\infty dk_+ \delta(M(1 - z) - k_+) \times
\]

\[
x \times \int_0^\infty dx \left( \delta(x), \frac{h_o - E_n}{h_o - E_n + \frac{k_+}{2} + x} \right) - \frac{h_o - E_n}{h_o - E_n + \frac{k_+}{2} + x} \delta(x) \frac{h_o - E_n}{h_o - E_n + \frac{k_+}{2} + x} \right)_{x, x'}
\]

where we have introduced the change of variables \( |k_+| = \sqrt{2k_+ x} \). Restricting ourselves to the ground state \( (n = 1) \) and using the techniques of reference 20 we obtain

\[
\text{Im} \left( T_{(\tilde{s}, \tilde{s}_0)}^{\alpha \alpha'}(z) \right) = -\eta_\perp^{\alpha\alpha'} \frac{16}{3} T_F^2 \left( \frac{c_F}{2m} \right)^2 \alpha_s(\mu_u) C_F \frac{1}{M} \int_0^\infty dk_+ \delta(M(1 - z) - k_+) \times
\]
\[ \times \int_0^\infty dx \left( 2\psi_{10}(0)I_S\left(\frac{k_+}{2} + x\right) - I_S^2\left(\frac{k_+}{2} + x\right) \right) \]

\[ I_S\left(\frac{k_+}{2} + x\right) := \int d^3x\psi_{10}(x) \left( \frac{h_o - E_1}{h_o - E_1 + \frac{k_+}{2} + x} \right)_{x,0} = \]

\[ = m\sqrt{\frac{\gamma}{\pi}}\frac{\alpha_s N_c}{2} \frac{1}{1 - z'} \left( 1 - \frac{2z'}{1 + z'} \right)^2 \left( -\frac{\lambda}{z'} \right) \left( 1 + \frac{\lambda}{z'} \right) \left( 1 - \frac{1 - z'}{1 + z'} \right) \left( 1 + \frac{1 - z'}{1 + z'} \right) \]

(11)

where

\[ \gamma = \frac{mC_f\alpha_s}{2} \quad z' = \frac{\kappa}{\gamma} - \frac{\kappa^2}{m} = E_1 - \frac{k_+}{2} - x \quad \lambda = -\frac{1}{2N_cC_f} \]

\[(E_1 = -m(\frac{C_f\alpha_s}{4})^2 = \frac{-2\alpha_s}{m}). \] This result can be recast in the factorized form given in [11].

\[ \text{Im} \left( T_{(8,1S_0)}(z) \right) = -\eta_{a'a'}^m \delta_{ij} \int d\lambda \frac{I_1}{S_1} \text{Im}J_M(l_+ - M(1 - z)) \]

\[ \text{Im}J_M(l_+ - M(1 - z)) = T_F^2 \left( N_c^2 - 1 \right) \frac{2\pi}{M} \delta(M(1 - z) - l_+) \]

\[ S_1(l_+) = \frac{4\alpha_s(\mu_u)}{3\pi N_c} \left( \frac{c_F}{2m} \right)^2 \int_0^\infty dx \left( 2\psi_{10}(0)I_S\left(\frac{l_+}{2} + x\right) - I_S^2\left(\frac{l_+}{2} + x\right) \right) \]

(13)

We have thus obtained the S-wave color octet shape function \( S_1(l_+) \). Analogously, for the P-wave color octet shape functions, we obtain from the second diagram of Fig. 11.

\[ \text{Im} \left( T_{(8,8P_{ij})}^2(\frac{\alpha_s}{m}) \right) = -\eta_{a'a'}^m \delta_{ij} \int d\lambda \left( \delta_{ij} S_1(l_+) + \left( n_i n_{i'} - \frac{1}{2} \delta_{ij}^{i'} \right) S_2(l_+) \right) \text{Im}J_M(l_+ - M(1 - z)) \]

\[ S_1(l_+) := \frac{\alpha_s(\mu_u)}{6\pi N_c} \int_0^\infty dx \left( 2\psi_{10}(0)I_P\left(\frac{l_+}{2} + x\right) - I_P^2\left(\frac{l_+}{2} + x\right) \right) \]

\[ S_2(l_+) := \frac{\alpha_s(\mu_u)}{6\pi N_c} \int_0^\infty dx \left( \frac{8l_+ x}{(l_+ + 2x)^2} \left( \psi_{10}^2(0) - 2\psi_{10}(0)I_P\left(\frac{l_+}{2} + x\right) + I_P^2\left(\frac{l_+}{2} + x\right) \right) \right) \]

(14)

where

\[ I_P\left(\frac{k_+}{2} + x\right) := -\frac{1}{3} \int d^3xx^i\psi_{10}(x) \left( \frac{h_o - E_1}{h_o - E_1 + \frac{k_+}{2} + x} \right)^{\nabla^i} \]

\[ = \sqrt{\frac{\gamma}{\pi}}\frac{8}{3} \left( 2 - \lambda \right) \frac{1}{4(1 + \lambda)^\frac{3}{2}} \left( 2(1 + z')(2 + z') + (5 + 3z')(1 + \lambda) + 2(-1 + \lambda)^2 + \right. \]

\[ + \left. \frac{1}{(1 - z')^2} \left( 4z'(1 + z')(z^2 - \lambda^2) \left( -1 + \frac{\lambda(1 - z')}{(1 + z')^2(z^2 - \lambda)} \right) + 2F_1 \left( -\frac{\lambda}{z'}, 1 + \frac{1 - z'}{1 + z'} \right) \right) \right) \]

(15)

Note that two shape functions are necessary for the P-wave case. The three shape functions above are UV divergent and need regularization and renormalization. In order to regulate them at this order it is enough to calculate the ultrasoft loop (the integral over \( k \) in [11]) in D-dimensions (leaving the bound state dynamics in 3 space dimensions). The UV behavior can be easily obtained by making an expansion of \( I_S \) and \( I_P \) in \( 1/z' \), which is displayed in formulas [11].
\( \alpha \) of the Appendix. For the purpose of this section we only need the expansions up to order \( 1/z^2 \). The singular pieces read (\( D = 4 - 2\varepsilon \))

\[
S_{S}(l_+)|_{\varepsilon \to 0} \simeq \frac{4\alpha_s(\mu_\gamma)\gamma^5}{3\pi^2 N_c m^2}(1 - \lambda) (-2 + \lambda(2\ln 2 + 1)) \left( \frac{1}{\varepsilon} + \ln \left( \frac{\mu}{L_{\varepsilon} + 2\varepsilon} \right) + \cdots \right)
\]

\[
S_{P_1}(l_+)|_{\varepsilon \to 0} \simeq \frac{4\alpha_s(\mu_\gamma)\gamma^5}{9\pi^2 N_c m^2}(2 - \lambda) \left( -\frac{17}{6} + \lambda(2\ln 2 + \frac{1}{6}) \right) \left( \frac{1}{\varepsilon} + \ln \left( \frac{\mu}{L_{\varepsilon} + 2\varepsilon} \right) + \cdots \right)
\]

\[
S_{P_2}(l_+)|_{\varepsilon \to 0} \simeq \frac{\alpha_s(\mu_\gamma)l_+^3\gamma^3}{3\pi^2 N_c} \left( \frac{1}{\varepsilon} + \ln \left( \frac{\mu}{L_{\varepsilon}} \right) + \cdots \right)
\]

The renormalization is not straightforward. We will assume that suitable operators exists which may absorb the \( 1/\varepsilon \) poles so that a MS scheme makes sense to define the above expressions, and discuss in the following the origin of such operators. In order to understand the scale dependence of \( S_{P_2}(l_+) \) it is important to notice that it appears because the term \( k_+^2 \) in the collinear gluon propagator is neglected in \( \alpha_\gamma \). It should then cancel with an IR divergence induced by keeping the term \( k_+^2 \), which implies assuming a size \( M^2(1 - z) \) for it, and expanding the ultrasoft scales accordingly. We have checked that it does. However, this contribution cannot be computed reliably within pNRQCD (neither within NRQCD) because it implies that the \( k_- \) component of the ultrasoft gluon is of order \( M \) and, hence it becomes collinear. A reliable calculation involves (at least) two steps within the EFT strategy. The first one is the matching calculation of the singlet electromagnetic current at higher orders both in \( \alpha_s \) and in \( (k_+/M)^2 \) and \( k_+/M \). The second is a one loop calculation with collinear gluons involving the higher order singlet currents. Notice, before going on, that all divergences (and logarithms) of \( S_{S}(l_+) \) and \( S_{P_1}(l_+) \) in \( \alpha_\gamma \) are sensible to the bound state dynamics, whereas those for \( S_{P_2}(l_+) \) are not. For the former, Fig. 2 shows the relevant diagrams which contribute to the IR behavior we are eventually looking for. We need NNLO in \( \alpha_s \), but only LO in the \( (k_+/M)^2 \) and \( k_+/M \) expansion. These diagrams are IR finite, but they induce, in the second step, the IR behavior which matches the UV of \( \alpha_\gamma \). The second step amounts to integrating out the scale \( M\sqrt{1 - z} \) by calculating the loops with collinear gluons and expanding smaller scales in the integrand. We have displayed in Fig. 3 the two diagrams which provide the aforementioned IR divergences. For the latter, the UV behavior of which does not depend on the bound state dynamics, we need the matching at LO in \( \alpha_s \) (last diagram in Fig. 2) but NLO in \( k_+/M \) and \( (k_+/M)^2 \). We have checked that the coefficient of the logarithm coincides with that of the \( (1 - z)\log(1 - z) \) term in the QCD calculation \( \alpha_\gamma \), as it should.

The above means that the scale dependence of the leading order contributions of the color-octet currents is of the same order as the NNLO contributions in \( \alpha_\gamma \) of the color-singlet current, a calculation which is not available. One might, alternatively, attempt to resum logs and use the NLO calculation \( \alpha_\gamma \) as the boundary condition. This log resummation is non-trivial. One must take into account the correlation of scales inherent to the non-relativistic system \( \alpha_\gamma \), which in the framework of pNRQCD has been implemented in \( \alpha_\gamma \). and combine it with the resummation of Sudakov logs in the framework of SCET \( \alpha_\gamma \) (see also \( \alpha_\gamma \)). Correlations within the various scales of SCET may start playing a role here as well \( \alpha_\gamma \). In any case, it should be clear that by only resumming Sudakov logs, as it has been done so far \( \alpha_\gamma \), one does not resum all the logs arising in the color octet contributions of heavy quarkonium, at least in the weak coupling regime.

III. APPLICATION TO THE \( \Upsilon(1S) \)

We apply here the results of section \( \alpha_\gamma \) to the \( \Upsilon(1S) \). There is good evidence that the \( \Upsilon(1S) \) state can be understood as a weak coupling (positronium like) bound state \( \alpha_\gamma \). Hence, ignoring \( O(\Lambda_{\text{QCD}}) \) in the shape functions, as we did in section \( \alpha_\gamma \), should be a reasonable approximation. In the analysis of \( \alpha_\gamma \), the effects of the octet shape functions were set to zero, so we expect to improve on their results. We plot in Fig. 4 the CLEO data in the end point region \( \alpha_\gamma \), the curve obtained in \( \alpha_\gamma \) (dashed line) and our curves (solid and dot-dashed lines). Our curves are obtained by adding to the results of \( \alpha_\gamma \), which consist of the LL resummation of the singlet contributions only, our (MS) results for the color octet contributions (without LL resummation \( \alpha_\gamma \)) and setting the scale dependence to \( \mu = M\sqrt{1 - z} \) (solid line) and to \( \mu = 2^{-1/2}M\sqrt{1 - z} \) (dot-dashed lines). The first choice is the most reasonable one according to the discussion in the previous section and the last ones are displayed in order to get the flavor of the systematic errors. We have used the following values for the masses and \( \alpha_s \) in our plots: \( m_0 = 4.8 \text{ GeV}, M_T = 9.46 \text{ GeV} \), \( \alpha_s(\mu_h) = 0.216 \), \( \alpha_s(\mu_s) = 0.32 \) and \( \alpha_s(\mu_a) = 0.65 \). \( \mu_h \sim m \) stands for the hard scale and is to be used for the
α_s arising from (3). \( \mu_s \sim m_{\alpha_s} \) stands for the soft scale and is to be used for the \( \alpha_s \) participating in the bound state dynamics (in \( E_1, I_5, I_P \) and \( \psi_{10}(0) \)). \( \mu_u \sim m_{\alpha_s}^2 \) stands for the ultrasoft scale and is to be used for the \( \alpha_s \) arising from the coupling of ultrasoft gluons. It turns out that the color octet contribution is numerically enhanced and dominates over the color singlet one in the whole end-point region. In order to compare with the experimental curve, the theoretical result must be convoluted with the experimental efficiency [12] and the overall normalization must be taken as a free parameter. By adjusting our curves to data around \( z \sim 0.7 \), we obtain an almost perfect agreement in the whole end-point region \((z \in [0.7, 1])\) for \( \mu = M/\sqrt{1-z} \) (solid line). A complete analysis, including systematic errors, is beyond the scope of this paper. It would require either a NNLO matching or a NLO one [24] with NLL resummation of the singlet current. In addition one should estimate what the leading non-perturbative effects are. In any case, it should be clear from our results that the introduction of a gluon mass [32] is not necessary for the description of the experimental data on the photon spectrum in the end-point region of \( \Upsilon(1S) \) radiative decays.

### IV. DISCUSSION

We would like to make a few remarks which stem from the details of our calculation. In the existing formulations of SCET, suitable scaling properties are assigned to the various modes. However the standard assignments are violated in our case. The collinear gluons in Fig. 1 scale as \( m(\lambda^2, 1, \lambda^2) \) rather than \( m(\lambda^2, 1, \lambda) (\lambda = \sqrt{1-z}) \), which is the assigned scaling in [3, 4, 5]. This indicates that SCET should better be discussed in terms of UV (and IR) cut-offs for the relevant modes, rather than scaling properties. This becomes particularly clear when we analyze the scaling of the ultrasoft gluon in the same diagrams. If \( m_{\alpha_s}^2 \sim M(1-z) \), it scales like \( m(\lambda^2, \lambda^2, \lambda^2) (\lambda = \alpha_s) \), which coincides with the standard scaling rules. If, however, \( m_{\alpha_s}^4 \sim M(1-z) \), it scales like \( m(\lambda^4, \lambda^2, \lambda^2) \), the typical scaling of the recently discovered soft-collinear modes [5]. Either scaling is properly described by the ultrasoft gluons of pNRQCD, since
they are defined as the ones having all four momenta much smaller than the soft scale \( \sim m_{Q_s} \) (UV cut-off), which is fulfilled in both cases. However, if one insisted to assign to the ultrasoft gluons a momentum scaling \( m(\lambda^2,\lambda^2,\lambda^2) \) and not smaller (i.e. one is introducing an IR cut-off for them), then the situation \( m_{Q_s}^4 \sim M(1-z) \) would require the introduction of new (ultra)soft-collinear modes scaling like \( m(\lambda^4,\lambda^2,\lambda^3) \) with an UV cut-off \( \sim m_{Q_s}^2 \) for the + and \( \perp \) components. Whether it is convenient or not to make such splitting is a matter of debate [5, 8].

The case \( m_{Q_s} \sim M(1-z) \) has not been discussed. For the color-octet contributions, it requires a calculation in NRQCD, since if one attempts at doing it from Fig. 1 one immediately realizes that the four momentum of the ultrasoft gluon is \( \sim m_{Q_s} \), a region where pNRQCD is not applicable. Hence at NRQCD+SCET level (Section II A) one should calculate a set of diagrams involving a collinear and a soft gluon. The leading order contribution comes from the S-wave current only and we have seen it to vanish.

We have refrained ourselves to put forward a Lagrangian for SCET which also holds for heavy quarkonium systems because several issues, like the remarks made above, should be better understood. Clearly, as we have shown in this paper, one cannot simply take over the SCET for heavy-light systems and apply it to heavy quarkonium (for instance, one misses logs which depend on the binding effects). Our analysis also indicates that it may be convenient to rephrase SCET in terms of cut-offs rather than in terms of scaling properties of the various modes as it has been done so far. Then, one would have to account properly for both the suitable cut-offs of pNRQCD and those of SCET.

V. CONCLUSIONS

Apart from making a few remarks, which we hope will be useful for an eventual construction of a SCET Lagrangian adapted to heavy quarkonium systems, we have calculated the \( S \)- and \( P \)-wave octet shape functions in the weak coupling regime. We have also discussed their scale dependence. The addition of these contributions to the ones obtained in [11] makes the agreement with data for the end point photon spectrum of inclusive \( \Upsilon(1S) \) decays almost perfect. As a by-product the NRQCD matrix elements \( \langle \Upsilon(1S)|O_8^{(1)}(S_0)|\Upsilon(1S)\rangle \) and \( \langle \Upsilon(1S)|O_8^{(3)}(P_{J})|\Upsilon(1S)\rangle \) have also been calculated, in the weak coupling regime, (see Appendix A) and their scale dependence discussed.
FIG. 5: Diagrams which require a $P_1(3S_1)$ operator for renormalization. The solid circle stands for either the $O_8(1S_0)$ or $O_8(3P_J)$ operator, the crossed box for either the chromomagnetic ($\bigstar$) or chromoelectric ($\circledast$) interaction in Fig. 1, the empty box for the octet Coulomb potential, and the thin solid lines for free $Q\bar{Q}$ propagators.

FIG. 6: Diagrams which require a $O_1(3S_1)$ operator for renormalization. Symbols are as in Fig. 5.

Acknowledgments

We have benefited from informative discussions on SCET with C. Bauer, T. Becher, M. Beneke, S. Fleming, T. Mehen, M. Neubert and I. Stewart. J.S. thanks the Benasque Center of Physics program Pushing the limits of QCD, and P. Bedaque for the opportunity to participate in the Effective Summer in Berkeley, where some of these discussions took place. Thanks are also given to D. Besson for providing the data of Ref. [12] and to Ll. Garrido for his help in handling it. Finally, we thank A. Penin, and, specially, A. Pineda for useful discussions on the Appendix A. We acknowledge financial support from a CICYT-INFN 2003 collaboration contract, the MCyT and Feder (Spain) grant FPA2001-3598, the CIRIT (Catalonia) grant 2001SGR-00065 and the network EURIDICE (EU) HPRN-CT2002-00311. X.G.T. acknowledges a FI fellowship from the Departament d’Universitats, Recerca i Societat de la Informació of the Generalitat de Catalunya.

APPENDIX A: CALCULATION OF $\Upsilon(1S)$ NRQCD COLOR OCTET MATRIX ELEMENTS

The calculation in Section II.C can be easily taken over to provide a calculation of $\langle \Upsilon(1S)| O_8(1S_0)|\Upsilon(1S)\rangle$ and $\langle \Upsilon(1S)| O_8(3P_J)|\Upsilon(1S)\rangle$ assuming that $m_\alpha^2 \gg \Lambda_{QCD}$ is a reasonable approximation for this system. Indeed, we only have to drop the delta function (which requires a further integration over $k_+$) and arrange for the suitable factors in (13) and (14). We obtain

$$\langle \Upsilon(1S)| O_8(1S_0)|\Upsilon(1S)\rangle = -2T_2^2(N_0^2 - 1) \int_0^\infty dk_+ S_{S}(k_+)$$

$$\langle \Upsilon(1S)| O_8(3P_J)|\Upsilon(1S)\rangle = -\frac{4(2J + 1)T_2^2(N_0^2 - 1)}{3} \int_0^\infty dk_+ S_{P1}(k_+)$$

(A1)

where we have used

$$\int_0^\infty dk_+ S_{P2}(k_+) = \frac{2}{3} \int_0^\infty dk_+ S_{P1}(k_+)$$

(A2)
The expressions above contain UV divergences which may be regulated in the same way as in Section II C, namely by calculating the ultrasoft loop in $D$ dimensions. These divergences can be traced back to the diagrams in Fig. 5 and Fig. 6. Indeed, if we expand $I_S$ and $I_P$ for $z'$ large, we obtain

$$I_S \sim m \sqrt{\frac{\gamma}{\pi}} \frac{\alpha_s N_c}{2} \{ \frac{1}{z'} + \frac{1}{z'^2} (-1 + 2\ln 2) + \frac{1}{z'^3} \left( 1 - 2\lambda + \frac{\lambda^2 \pi^2}{6} \right) + \frac{1}{z'^4} \left( -1 + \lambda(2\ln 2 + 1) + \lambda^2 (-4\ln 2) + 3\zeta(3) \lambda^3 \right) + \mathcal{O}(\frac{1}{z'^5}) \}$$

$$I_P \sim \sqrt{\frac{\gamma}{\pi}} \frac{8}{3} (2 - \lambda) \left\{ \frac{1}{2z'} + \left( -\frac{3}{4} + \lambda \left( -\frac{1}{4} + \ln 2 \right) \right) \frac{1}{z'^2} \right. + \left. \left( 1 - \lambda + \frac{1}{12} (-6 + \pi^2) \lambda^2 \right) \frac{1}{z'^3} + \frac{1}{4} (-5 + \lambda + \lambda^2 (2 - 8 \ln 2) + 8 \lambda \ln 2 + \lambda^3 (-4 \ln 2 + 3 \zeta(3))) \right\}$$

(A3)

(A4)

It is easy to see that only powers of $1/z'$ up to order four may give rise to divergences. Moreover, each power of $1/z'$ corresponds to one Coulomb exchange. Taking into account the result of the following integral,

$$\int_0^\infty dk_+ \int_0^\infty dx (2k_+x)^{-\varepsilon} \frac{1}{x^{z\delta}} = 2^{1-2\varepsilon} \left( \frac{\gamma^2}{m} \right)^{2-2\varepsilon} \frac{2\zeta(2 - \varepsilon) \Gamma \left( 1 - \frac{\alpha}{2} + 2\varepsilon - 2 \right)}{\Gamma \left( \frac{3}{2} \right) \Gamma \left( \frac{3}{2} - \varepsilon \right)}$$

(A5)

we see that only the $1/z'^2$ and $1/z'^4$ terms produce divergences. The former correspond to diagrams in Fig. 5 and the latter to Fig. 6, which can be renormalized by the operators $P_1 (3s_1)$ and $O_1 (3s_1)$ respectively. It is again important to notice that these divergences are a combined effect of the ultrasoft loop and quantum mechanics perturbation theory (ultrasoft loops) and hence it may not be clear at first sight if they must be understood as ultrasoft (producing log $\mu_u$ in the notation of Refs. 22, 23) or potential (producing log $\mu_p$ in the notation of Ref. 28, 29). In any case, the logarithms they produce depend on the regularization and renormalization scheme used for both ultrasoft and potential loops. Notice that the scheme we use in this work is not the standard one in pNRQCD 17, 28, 34. In the standard scheme the ultrasoft divergences (anomalous dimensions) are identified by dimensionally regulating both ultrasoft and potential loops and subsequently taking $D \to 4$ in the ultrasoft loop divergences only. If we did this in the present calculation we would obtain no ultrasoft divergence. Hence, in the standard scheme there would be contributions to the potential anomalous dimensions only. The singular pieces in our scheme are displayed below

$$\langle \Upsilon(1S) | O_8 (1S_0) | \Upsilon(1S) \rangle \bigg|_{\varepsilon \to 0} \simeq -\frac{1}{\varepsilon} \left( \frac{2\gamma}{\mu m} \right)^{-2\varepsilon} \frac{1}{24} C_F^2 N_c \alpha_s(\mu_u) (C_F \alpha_s(\mu_u))^4 \frac{\gamma^3}{\pi^2} \left( 2 + \lambda [ -7 - 4 \ln 2 ] + \lambda^2 \left[ 4 + 8 \ln 2 + 4 \ln^2 2 + \frac{\pi^2}{3} \right] + \lambda^3 \left[ -4 \ln^2 2 - \frac{\pi^2}{3} - \frac{3}{2} \zeta(3) \right] \right)$$

$$\langle \Upsilon(1S) | O_8 (3P_3) | \Upsilon(1S) \rangle \bigg|_{\varepsilon \to 0} \simeq -(2J + 1) \frac{1}{\varepsilon} \left( \frac{2\gamma}{\mu m} \right)^{-2\varepsilon} \frac{4}{24} C_F \alpha_s(\mu_u) (C_F \alpha_s(\mu_u))^2 \frac{\gamma^5}{\pi^2} \times (2 - \lambda) \left[ 4 + \lambda \left[ \frac{47}{12} + 5 \ln 2 \right] + \lambda^2 \left[ 5 \ln 2 - \frac{2\pi^2}{9} - \frac{8}{3} \ln 2 - \frac{8}{3} \ln^2 2 \right] + \lambda^3 \left[ -\frac{7}{12} + \frac{\pi^2}{9} - \frac{5}{3} \ln 2 + \frac{4}{3} \ln^2 2 + \frac{3}{4} \zeta(3) \right] \right]$$
