Abstract

**Background:** Erectile dysfunction is one of the common complications of testicular cancer with the prevalence of 11.3% to 84%. It has devastating effects on men and partner’s quality of life, sexual satisfaction, and sexual experience. The findings of the previous studies on this matter were uneven and inconsistent. Therefore, this systematic review and meta-analysis is conducted in order to acquire a more recent and comprehensive result.

**Methods and materials:** To search and retained all the eligible articles different databases were searched. These includes PubMed, Scopus, Goggle scholar, Science Direct, African Index Medicus, African Journal online, EMBASE, and Cochrane Library. To extract all the relevant information, a standardized data extraction checklist was prepared. STATA 14 statistical software was utilized to analyze the data. $I^2$ statistics was employed to check for the heterogeneity of studies. Using a funnel plot and Egger's regression test publication bias was checked. Then, a random-effect model was computed to estimate the pooled prevalence of erectile dysfunction.

**Result:** Fourteen full-text studies were included in this systematic review and meta-analysis. The pooled prevalence of erectile dysfunction among testicular cancer survivors was found to be 34.60% (95% CI: 25.89, 43.30% [$I^2 = 95.9\%, \ p = 0.000$]). Study design subgroup analysis indicated that the pooled prevalence of erectile dysfunction was 50.02% (95% CI: 22.78, 77.28% [$I^2 = 96.1\%, \ p = 0.000$]) and 27.36% (95% CI: 19.23, 34.48% [$I^2 = 91.6\%, \ P = 0.000$]) in the case control and cohort studies respectively. Likewise, the level of erectile dysfunction was varied based on erectile dysfunction measuring tools and testicular cancer treatment modalities.

**Conclusion:** The pooled prevalence of erectile dysfunction in testicular cancer survivors was found to be high. It had also a considerable discrepancy between the study designs, and measuring
tools and treatment modalities of testicular cancer. Therefore, there is a sound to diminish the high burden of this problem.

**Keywords:** Testicular cancer, erectile dysfunction, pooled prevalence, clinical research, chronic diseases.
1. Introduction:
Testicular cancer (TC) is a malignant tumor of the male sex organ mainly affect reproductive age groups [1]. The global incidence of testicular cancer showed a 1.80 doubling increase from 37,231 in 1990 to 66,833 new cases in 2016 [2].

Testicular cancer survivors are at greater risk of reduced sexual interest, sexual activity, sexual enjoyment, erectile dysfunction (ED), ejaculatory problems, increased sexual discomfort and changes in body image as compared with the healthy male population [3]. It has a paramount and persistent impact on a patient’s sexuality due to its location and treatments [4].

Erectile dysfunction (ED), is the inability to gain or sustain an erection steady enough for sexual intercourse [5]. ED may be provoked by different factors including the adverse effects of cancer treatment, such as fatigue, pain, or anxiety related to the cancer therapy and depressed moods about the diagnosis of cancer [5].

ED can be happen in the form of organic and/or psychogenic [3]. Organic ED resulting from the effects of radiotherapy and chemotherapy, whereas psychogenic ED is associated with changes in body image, loss of sense of manliness after orchiectomy, reduced spirits of well-being and other psychosocial fluctuations associated with cancer [3].

Erectile dysfunction is one of the common complications of testicular cancer with a prevalence of 11.3% to 84%, according to different studies [3, 6]. It has devastating effects on men and partner’s quality of life, sexual satisfaction, and sexual experience [7, 8]. Its impact is not only related to the sexual life of the survivors rather than it comprises psychological, biological, relational, and cultural elements of life [9].
Treatment modalities, psychological emotion, relationship, body image, types of testicular cancer, patient age and degree of ED before starting cancer treatment are some of the determinants that affect the erectile function of testicular cancer survivors [1, 5, 10-15]

Nowadays the prevalence of ED is increased due to the increment of testicular cancer survivors and decrement the mortality rate of testicular cancer patients [2]. The progressively increasing number of survivors and succeeding accomplishment of primary cancer treatments, causes specific complications continue to affect cancer survivors negatively [4, 16].

However, the number of testicular cancer survivors is steadily increasing with decreasing mortality rate and with the increment of complications, including erectile dysfunction in the last two decades [2, 16]. The findings of the previous studies on this matter were uneven and inconsistent. Hence, designed and applied rationalized intervention for currently existed erectile dysfunction in testicular cancer survivors by using those fragmented study findings as evidence is not acceptable.

Therefore, we decided to conduct a systematic review and meta-analysis of the existing data in order to acquire a more recent and comprehensive result. This evidence will give a new information for policy makers, which enables them to design scientific directives to decrease the magnitude of ED among testicular cancer survivors.
2. Methods

2.1. Protocol and registration

The findings of this review were reported, according to the preferred reporting item on systematic review and meta-analysis statement [17]. It is not registered in the Prospero database.

2.2. Eligibility criteria

The inclusion criteria were: 1. Any primary studies that clearly reported the prevalence of erectile dysfunction among testicular cancer survivors, 2. Studies conducted between 2001 and 2020, 3. Studies published in English, 4. Studies available at the electronic source before July 2020. On the other hand, qualitative studies, citations without complete abstract and/or full text, anonymous reports, editorials, conference presentations, letters, expert opinions, case reports, and duplications were excluded.

2.3. Information source

PubMed, Scopus, Goggle scholar, Science Direct, African Index Medicus, African Journal online, EMBASE, and Cochrane Library up to July 2020. Furthermore, the reference lists of related papers were also plaid to identify additional studies. And articles with incomplete data were accessed by communicating with the corresponding author.

2.4. Searching strategy

The main search terms and phrases were “prevalence”, “magnitude”, “epidemiology”, “proportion”, “erectile dysfunction”, “sexual dysfunction”, “impotence”, “sexual disorder”, “testicular cancer” and “testicular tumor”, testicular neoplasm”, survivors,” patients”. “OR” and “AND” were used discretely and together as Boolean operators.
2.5. Study selection

Duplicate articles were removed using Endnote version 7 referencing software. The title and abstract section of all the retained articles were reviewed and screened by five independent reviewers. In case of any disagreement, it was handled based on established article selection criteria.

2.6. Data extraction

Data was extracted by adopting the Joanna Briggs Institute (JBI) data extraction format [18]. Five authors (SK, YW, AS, EA, and MM) independently extracted all necessary data using this format. The data extraction format included primary author, publication year, country, region, measuring tool, study design, response rate, sample size, and prevalence.

2.7. Outcome measurement

The outcome variable of study was erectile dysfunction in testicular cancer, which is the inability to obtain or maintain an erection firm enough for sexual intercourse was measured by different tools [5]. The pooled prevalence was calculated by dividing the total number of erectile dysfunction in all review studies to the total number of involved testicular cancer survivors in the study and multiplying by 100 [19]. Erectile dysfunction = (Number of erectile dysfunction/number of participants) *100.

2.8. Quality assessment

The Newcastle-Ottawa Quality Assessment tool was used to check the quality of studies in this review [20]. The assessment tool contains 1) representativeness of the sample, 2) sample size, 3) non-respondents and 4) ascertainment of the exposure, 5) independent blind assessment and 6)
statistical test). Finally, based on this tool, article with a scale of 6 out of 10 was considered as good quality. Each original study was evaluated by five authors independently using this tool. If there were disagreements between those five authors, the consensus was reached by taking the mean score of the five authors.

**Statistical analysis**

Publication bias was checked by funnel plot and more objectively through Begg's and Egger's regression test [21]. Heterogeneity of studies was quantified using the I-Squared Statistic, in which 25, 50, and 75% represented low, moderate and high heterogeneity respectively [22, 23]. Pooled analysis was conducted using a weighted inverse variance random-effects model [24]. Subgroup analysis was done by treatment modalities, and erectile dysfunction measuring tools. Sensitivity analysis was employed to see the effect of single study on the overall estimation. STATA version 14 statistical software was used for meta-analysis.
3. Results

3.1. Characteristics of reviewed studies

Originally, 82 records were collected in relation to erectile dysfunction in testicular cancer survivors PubMed, Google scholar, Africa Index Medicus, Africa Journal Online, EMBASE, and Science Direct databases. Twenty studies were investigated from other sources. From these, 70 were not considered for further evaluation as a result of duplication and title and abstract did not appropriate search criteria. From the rest 32 articles, 11 were excluded because there were out of interest. Therefore, 21 full-text articles were retrieved and evaluated for eligibility based on the inclusion criteria. Seven articles were excluded as a result of not fulfilling our inclusion criteria [1, 3, 4, 6, 10, 12, 14, 15, 25-37]. Finally, 14 studies that fulfilled the eligibility criteria were included in the systematic review and meta-analysis (Figure 1).

Data for the fourteen eligible studies were extracted and analyzed in this study. The pooled prevalence of erectile dysfunction was estimated by using 7043 testicular cancer survivors.
Figure 1. Flowchart to a selection of studies for a systematic review and meta-analysis of the prevalence of erectile dysfunction, 2020.
### 3.1.1. Quality appraisal

The Newcastle-Ottawa Scale quality appraisal criteria was used. The studies included in this systematic review and meta-analysis had no low quality. Therefore, all fourteen studies were included (Table 1).

**Table 1: Scoring of the quality of articles by authors using The Newcastle-Ottawa Quality Assessment tool.**

| Study | Quality selection | Comparability | Outcome | Total Score |
|-------|-------------------|---------------|---------|-------------|
|        | Quality assessor | Representativeness of sample | Non-respondents | Ascertaintment | Study controls for most important factor | The study control for any additional factor | Assessment of the outcome | Statistical test |

3.2. Meta-analysis

3.2.1. Prevalence of erectile dysfunction

In this study, the pooled prevalence of erectile dysfunction among testicular cancer survivors was found to be 34.60% (95% CI: 25.89, 43.30%). Severe heterogeneity was detected across the studies ($I^2 = 95.9\%, p = 0.000$) (Figure 2).
3.2.2. Subgroup analysis

After the heterogeneity statistics has been done, we carried out subgroup analysis based on the study design, treatment and measuring tools. In this regard, the prevalence was higher in the case control study, 50.02% (95% CI: 22.78, 77.28% [I² = 96.1, p = 0.000]) as compared with cohort study, 27.36% (95% CI: 19.23, 34.48% [I² = 91.6, P = 0.000]). The prevalence of erectile dysfunction measured by IIEF was higher than the prevalence measured by other measuring tools. The prevalence of erectile dysfunction among those who were treated with three treatment modalities (radiation, surgery and chemotherapy) was also higher than those who were treated with less than three treatment modalities (Table 2).
Table 2. Subgroup analysis of prevalence of erectile dysfunction among testicular cancer survivors, 2020.

| Variables               | Characteristics        | Estimates (95%CI)         | I² tests with p-value |
|-------------------------|------------------------|--------------------------|-----------------------|
| Study designs           | Case control           | 50.02% (22.78, 77.26%)   | 96.1%, P=0.000        |
|                         | Cohort                 | 27.36% (19.23, 35.48%)   | 91.6%, P=0.000        |
|                         | Cross-sectional        | 38.66% (19.82, 57.51%)   | 97.4%, P=0.000        |
| Treatment modalities    | Three treatments       | 45.46% (27.23, 63.70%)   | 97.5%, P=0.000        |
|                         | Less three treatments  | 26.5% (20.29, 32.71%)    | 87.3%, P=0.000        |
| Measuring tools         | IIEF                   | 40.50% (25.42, 55.58)    | 97.5%, P=0.000        |
|                         | BMSFI                  | 31.49% (22.48, 40.50)    | 71.9%, P=0.06         |
|                         | Others                 | 24.48% (18.30, 30.66)    | 74.7%, P=0.008        |

Others= International Index of Erectile Function and Brief Sexual Function Inventory, European Organization for Research and Treatment of Cancer (EORTC QLQ-PR25), nine-item generic questionnaire, adverse health outcomes

To estimate the pooled prevalence of erectile dysfunction a random-effect model was employed to this analysis. The study design, publication year, sample size and response rate were inspected using multivariate meta-regression model whether they were associated with the heterogeneity. As the model shows, none of them were statistically significant (Table 3).
Table 3. Related factors with heterogeneity of erectile dysfunction prevalence among testicular cancer survivor’s in the current meta-analysis, 2020.

| Variables        | Coefficient     | P-value |
|------------------|-----------------|---------|
| Study design     | -18.72 (-57.72, 20.27) | 0.300   |
| Publication year | .533 (-2.94, 4.01) | 0.733   |
| Sample size      | -.011 (-.035, .013) | 0.340   |
| Response rate    | .092 (-.879, 1.063) | 0.833   |

3.2.2.1. Publication bias.

To assess publication bias, the funnel plot and Egger’s test were conducted in the meta-analysis (Figure 3). The result of the Egger test was also statistically significant with Bo =3.33 and p < 0.001. To see publication bias further, trim fill analysis was done, and unpublished studies were not found.
Figure 3. Funnel plot for publication bias, logprop or ln p (log of proportion) represented in the X-Axis and standard error of log proportion in the Y-Axis.

3.2.2.2. Sensitivity analysis

Among all fourteen reviewed studies in the current analysis, no study had shown an impact on the overall estimation (Figure 4).

| Study                          | Lower CI Limit | Estimate | Upper CI Limit |
|-------------------------------|----------------|----------|----------------|

Figure 4. The sensitivity analysis showed the pooled prevalence when the studies omitted step by step.
4. Discussion

This meta-analysis showed that the pooled prevalence of erectile dysfunction among testicular cancer survivors was 34.6%. This pooled prevalence of erectile dysfunction among testicular cancer survivors is higher than studies conducted in the London 8% [35], China 16.9% [38], and Netherlands 11.5% [39].

This discrepancy may be due to the age difference of study participants, the time of study, study design, types of testicular cancer (unilateral or bilateral), and treatment modalities. A study conducted in London included only young men (16-39 years old). But the current study includes all age groups and older age increases the prevalence of erectile dysfunction [5, 40]. In the case of a study conducted in China, the study was only included case control studies and patients experienced unilateral orchiectomy nevertheless this systematic review and meta-analysis study includes any primary studies that clearly reported the prevalence of erectile dysfunction among testicular cancer survivors and patients underwent both unilateral orchiectomy and/or bilateral orchiectomy. Evidence supported that bilateral orchiectomy had an associated with the prevalence of erectile dysfunction in testicular cancer survivors due to complete cessation or very low production of testosterone [31]. And, the discrepancy between a study conducted in Netherland and this study may be due to the time variation and the study design that included in the systematic review and meta-analysis. A study done in Netherland was conducted before two decades and included only cohort studies conducted from 1975 to 2000. But the current study includes all primary studies conducted from 20001 to 2020. In the last two decades the survival rate of testicular cancer is highly increased, this in turn increases the prevalence of erectile dysfunction in testicular cancer survivors due to long effects of testicular cancer complications [30].
Subgroup analysis piercing out that the prevalence of erectile dysfunction was 45.46% among those who were treated with three treatment modalities and the prevalence of erectile dysfunction was 26.5% among those testicular cancer survivors treated with less than three treatment modalities. This indicated that substantial heterogeneity of the prevalence of erectile dysfunction across treatment modalities. This variance might be due to the synergistic effect of three treatment modalities on erectile function. Evidence showed that Chemotherapy, surgery, and radiation can all cause sexual antagonistic effect by causing neuropathy, nerve disconnected and interruption of normal blood supply to maintain erection and vasculogenic respectively [3, 5]. The combination of these treatments has much more negative effect on erection than treatments less than this combination.

The heterogeneity of erectile dysfunction prevalence is also seen across different measurement tools. The prevalence of ED in the studies used IIEF as a criterion tool was higher than other studies which were used BMSFI and others criterion tools. This might be due to the different cut points to determine erectile dysfunction among tools. This finding is supported by a study conducted in China [38].

The result of this study will have its own limitations. In doing this research we only considered articles that reported their findings using English language. The other limitation is that the severity of ED was not measured and described because of lack of sufficient information from the studies. Subgroup analysis using age was not done due to lack of data in the included studies. All the articles included to this study were conducted in Europe or America. Hence, the results may not be inferred to patients in Asia or Africa.
5. **Conclusion**

There was a high prevalence of erectile dysfunction in testicular cancer survivors. It had also causes of heterogeneity in terms of treatment modalities, study designs and measuring tools. Hence, there is a trepidation for responsible bodies to prevent the high level of this complication.
