Numerical Investigation of the Dynamic Responses of Fibre-Reinforced Polymer Composite Bridge Beam Subjected to Moving Vehicle

Eva Kormanikova 1,*, Kamila Kotrasova 1, Jozef Melcer 2 and Veronika Valaskova 2, *

Abstract: In modern industry, heavy traditional materials are being substituted with light and strong fibre-reinforced polymer composite materials. Bridges and railroads made of composite laminates are considerably affected by traffic loads. Therefore, it is very important to analyse this effect which would find practical applications in engineering designs. This paper explains the theoretical formulation that governs the dynamic response of a composite beam subjected to a moving load. The governing equations for the dynamic effect on the laminated composite bridge beam are explained here. The main theories in the micro–macro modelling of composite laminates are also described in the paper. Within the macro modelling, the Classical Laminate and Shear Deformation Laminate Theory of beams are presented. The symmetric cross-ply laminated bridge, made of boron/epoxy is under consideration. The computational two-dimensional model of the vehicle is adopted. The governing equations for the dynamic effect on the laminated composite bridge beam are explained. The calculation of the time response of the bridge for the characteristic speeds of the vehicle is performed in the environment of the MATLAB software. The maximum dynamic magnification factor for the dynamic analysis of a composite beam is found.

Keywords: fibre-reinforced composite; laminate; bridge beam; moving load; vibration

1. Introduction

The use of polymers in composite materials in modern engineering applications has been increasing rapidly [1]. The rapid growth in manufacturing industries has led to the need for the betterment of materials in terms of strength, stiffness, density, and lower cost with improved sustainability [2,3]. Composite materials have emerged as one of the materials possessing such betterment in properties serving their potential in a variety of applications [4–6].

Furthermore, the better fatigue performance [7], creep performance [8], and durability [9] of fibre-reinforced resin composites in the service environment are also the main factors to be considered compared to traditional steel. Fibre-reinforced polymer composites have great potential to replace steel for bridge cables, underground oil extraction, and ocean engineering, owing to their light weight, high strength, and desirable corrosion and fatigue resistance.

In modern engineering, the heavy beams of traditional materials are gradually being substituted by fibre-reinforced polymer composite beams of lower weight and higher strength. These beams are often considered important elements of structures. Structures such as railroads and bridges are always under the action of dynamic moving loads caused by the moving vehicular traffic. Therefore, the analysis of a laminated composite beam under the action of moving loads would find many practical applications and is of valuable
interest in engineering designs. The composite material for a specific application usually requires the use of angle-ply and unsymmetric laminates. Thus, bend–stretch, shear–stretch, and bend–twist couplings will be present in these laminates. The elementary or classical laminate theory (CLT) of beams assumes that the transverse shear strains are negligible and plane cross-sections before bending remain plane and normal to the axis of the beam after bending (Bernoulli–Euler beam theory). In the Bernoulli–Euler beam theory, the transverse deflection is assumed to be independent of coordinates $x_2, x_3$ of the cross-section. If the composite materials have a very low transverse shear modulus compared to their in-plane moduli, the CLT is inadequate for the analysis of dynamic response, and the shear deformation theory must be applied (Timoshenko beam theory). The first-order shear deformation theory accounted for a constant state of transverse shear stresses, but the transverse normal stress is often neglected. The most significant difference between the classical and first-order shear deformation theory is the effect of including transverse shear deformation.

There has not been much work completed on the study of composite beams under the action of moving loads, although several researchers have given theoretical [10–13], numerical [14–16], and experimental [17–19] analyses of traditional beams and plates under such conditions.

Considering the different size scales of the mechanical modelling of structure elements composed of fibre-reinforced composites, the micro, macro, and structural modelling levels must be considered. Within the microscale, the hybrid parallel approach to the homogenization of transport processes in masonry composites is described [20]. The non-local strain gradient nonlinear resonance of bi-directional functionally graded composite micro/nano-beams under periodic soft excitation is described in [21]. In the research in [22] was found a more intense shift of the first resonance frequency peak position to higher frequencies with increasing filler concentrations for HDPE/mica in comparison to HDPE/wollastonite composites. The research work [23] combines the scientific field of the micro–macro modelling of reinforced polymer composite laminates applied in the seismic response area of a rectangular composite tank filled with liquid. Frequency-dependent damped vibrations of multifunctional foam plates sandwiched and integrated by composite faces on the macroscale are explained in [24].

Fibre-reinforced polymer composites were originally developed for the aerospace and defence industries [25]. However, fibre-reinforced polymer composites have great potential for use in civil infrastructure [26]. One of their first uses was in an all-composite bridge superstructure in Miyun, China, in 1982 [27]. These materials are gradually gaining recognition from civil engineers as a new construction material [28]. Over the next few years, they proved successful in several areas of application: mainly in the form of sheets and strips for reinforcing existing bridge structures, as well as reinforcing bars, which replace the traditionally used steel reinforcement in concrete [29].

In this paper, a solution based on a CLT has been developed for the study of the dynamic response of an orthotropic laminated composite beam under the actions of moving loads [30–33]. The algorithm also accounts for the translatory and rotary inertia effects [34,35]. The differential equations are solved by numerical methods. The program MATLAB serves procedures for solving the differential equations of the first order by the Runge–Kutta–Fehlberg method [15]. The algorithm presented in this paper can be applied to moving loads with a constant-speed motion or constant-acceleration motion for the Bernoulli–Euler beam theory. A computer code has been developed for the analysis of orthotropic unsymmetric laminated composite beams under the action of moving loads.

2. Methods of Modelling and Analysis of Laminate Beam Theories

Summarizing the different size scales of the mechanical modelling of structure elements composed of fibre-reinforced composites, it must be noted that three modelling levels must be considered.
2.1. Microscale Level

For a composite with a random microstructure, it is suitable to use the periodic microstructure model. The model for long cylindrical fibres, regularly arranged in a square microstructure, is illustrated in Figure 1.

![Figure 1. A periodic microstructure model for effective elastic properties of a bundle.](image)

In the last decade, effective media theories, widely used in classical continuum micromechanics, have been recognised as an attractive alternative to FE-based methods. Since its introduction, the Mori–Tanaka (MT) method [25] has enjoyed a considerable interest in a variety of engineering applications. The Mori–Tanaka method considers the effect of phase interactions on the local stresses by assuming an approximation in which the stress in each phase is equal to that of a single inclusion embedded into an unbounded matrix subjected to a yet unknown average matrix strain.

The constitutive equation for unidirectional composite is written as

\[
\begin{bmatrix}
\sigma_1 \\
\sigma_2 \\
\sigma_3 \\
\sigma_4 \\
\sigma_5 \\
\sigma_6
\end{bmatrix} = \begin{bmatrix}
l & (k + m) & (k - m) & 0 & 0 & 0 \\
l & (k - m) & (k + m) & 0 & 0 & 0 \\
0 & 0 & 0 & m & 0 & 0 \\
0 & 0 & 0 & 0 & p & 0 \\
0 & 0 & 0 & 0 & 0 & p
\end{bmatrix} \begin{bmatrix}
\varepsilon_1 \\
\varepsilon_2 \\
\varepsilon_3 \\
\varepsilon_4 \\
\varepsilon_5 \\
\varepsilon_6
\end{bmatrix},
\]

where:

\[
k = -(1 / G_{23} - 4 / E_{22} + 4v_{12}^2 / E_{11})^{-1},
\]

\[
l = 2k v_{12},
\]

\[
m = G_{23},
\]

\[
n = E_{11} + 4k v_{12}^2 = E_{11} + l^2 / k,
\]

\[
p = G_{12}.
\]

From the application of the Mori–Tanaka method are obtained effective material characteristics at the microscale level, suitable for the 3D modelling of the composite structural element at the macroscale level.

A thin lamina is assumed to be under a state of plane stress. Two cases of material behaviour of laminae are of special interest for engineering applications:

Long fibres with one unidirectional fibre orientation, the so-called unidirectional laminae, or UD-laminae, with loading along the material axis (on-axis case). The elastic behaviour of UD-laminae depends on the loading reference coordinate systems. In the on-axis case, the reference axes (1, 2) are identical to the material or principal axes of the lamina parallel and transverse to the fibre direction (Figure 2). The 1-axis is also denoted as L-axis and the 2-axis as T-axis (on-axis case). The elastic behaviour is macroscopically quasi-homogeneous and orthotropic with four independent material moduli \( E_1 \equiv E_L \), \( E_2 \equiv E_T \), \( E_6 \equiv G_{12} = G_{LT} \), and \( v_{12} \equiv v_{LT} \).
The in-plane stress–strain relations are with

\[ \begin{align*}
E_{11} &= \frac{E_1}{1-\nu_{12}\nu_{21}} \\
E_{22} &= \frac{E_2}{1-\nu_{12}\nu_{21}} \\
E_{12} &= \nu_{12}E_{22} \\
E_{66} &= G_{12}.
\end{align*} \tag{3} \]

The relations of the in-plane stress components with the in-plane strain components are described by

\[ \mathbf{\sigma} = E \mathbf{\varepsilon} \Leftrightarrow \begin{pmatrix} \sigma_{11} \\ \sigma_{22} \\ \tau_{12} \end{pmatrix} = \begin{pmatrix} E_{11} & E_{12} & 0 \\ E_{12} & E_{11} & 0 \\ \text{sym.} & E_{66} & \tau_{12} \end{pmatrix} \begin{pmatrix} \varepsilon_{11} \\ \varepsilon_{22} \\ \gamma_{12} \end{pmatrix} \tag{4} \]

UD-lamina with loading along the arbitrary axis (\(x_1-x_2\)) is different from the material axis (off-axis case). The elastic behaviour is macroscopically quasi-homogeneous and anisotropic. The in-plane stress–strain relations are formulated by fully populated matrices with all components different from zero, but the number of independent material constants is still four.

Figure 3 illustrates qualitatively the on-axis elastic behaviour of the UD-lamina [26].

The values \(E_{ij}\) of the reduced stiffness matrix \(E\) depend on the effective moduli of the UD-lamina. These relations simplify the problem from a three-dimensional to a two-dimensional or plane stress state. For on-axis loading, the elastic behaviour is orthotropic with \(E_{16} = E_{26} = 0\), there is as in isotropic materials no coupling of normal stresses, and shear strains and shear stresses applied in the \((L-T)\)-plane do not result in any normal strains in the \(L\) and \(T\) direction. The UD-lamina is therefore also called an especially orthotropic lamina.

A unidirectional lamina has very low stiffness and strength properties in the transverse direction compared with these properties in the longitudinal direction.

---

Figure 2. Unidirectional lamina with principal material axis \(L = 1\) and \(T = 2\) (on-axis).

Figure 3. On-axis stress–strain for UD-lamina.
2.2. Mesoscale Level

Laminates are constituted generally of different layers at different orientations. To study the elastic behaviour of laminates, it is necessary to take a global coordinate system for the whole laminate and to refer the elastic behaviour of each layer to this reference system. The global material reference system is given in Figure 4.

![Figure 4. The global material reference system.](image)

We consider the ply material axes to be rotated away from the global axes by an angle \( \theta \), positive in the counterclockwise direction. This means that the \((x_1, x_2)\)-axes are at an angle \( \theta \) clockwise from the material axes. Thus, transformation relations are needed for the stresses, the strains, the stress–strain equations, the stiffness, and the compliance matrices.

Note the relations for the transformation matrices

\[
\hat{n}E = T^T(n \theta)(n)E_L T(n \theta)
\]

with transformation matrix for CLT

\[
T(\theta) = \begin{pmatrix} c^2 & s^2 & 2sc \\ s^2 & c^2 & -2sc \\ -sc & sc & c^2 - s^2 \end{pmatrix}
\]

and for shear deformation theory

\[
\bar{T}(\theta) = \begin{pmatrix} T(\theta) & 0 \\ 0^T & T^T(\theta) \end{pmatrix} = \begin{pmatrix} c^2 & s^2 & 2sc & 0 & 0 \\ s^2 & c^2 & -2sc & 0 & 0 \\ -sc & sc & c^2 - s^2 & 0 & 0 \\ 0 & 0 & 0 & c & s \\ 0 & 0 & 0 & -s & c \end{pmatrix}
\]

where

\[
\bar{T}(\theta) = \left(T^T(\theta)\right)^{-1}
\]

where \( c \) and \( s \) are noted as \( s = \sin \theta \) and \( c = \cos \theta \).

In the theory of laminates, the most complex problem is the modelling and analysis of laminate with an arbitrary stacking of the layers. These laminates present couplings of stretching and bending, stretching and twisting, bending and twisting and the design engineer must look for simplifications.

The first and most important simplification is to design symmetric laminates for which no coupling exists between the in-plane forces and flexural moments. The coupling terms \( B_{ij} \) of the constitutive equations vanish. An additional simplification occurs when no bending–twisting coupling exists, i.e., the terms \( D_{16} \) and \( D_{26} \) are zero. Symmetric laminates for which no bending–twisting coupling exists are referred to as especially orthotropic laminates. Symmetrically balanced laminates with a great number of layers have an especially orthotropic behaviour. This class of laminates is greatly simplified and will be used to gain a basic understanding of laminate structural element response.
The internal forces can be written in matrix form for CLT

\[
\begin{bmatrix}
N_x \\
N_y \\
N_{xy}
\end{bmatrix} =
\begin{bmatrix}
A_{11} & A_{12} & A_{16} \\
A_{21} & A_{22} & A_{26} \\
A_{61} & A_{62} & A_{66}
\end{bmatrix}
\begin{bmatrix}
\varepsilon_{xx} \\
\varepsilon_{yy} \\
\gamma_{xy}
\end{bmatrix} +
\begin{bmatrix}
B_{11} & B_{12} & B_{16} \\
B_{21} & B_{22} & B_{26} \\
B_{61} & B_{62} & B_{66}
\end{bmatrix}
\begin{bmatrix}
\kappa_x \\
\kappa_y \\
\kappa_{xy}
\end{bmatrix}
\] (9)

and for shear deformation theory

\[
\begin{bmatrix}
M_x \\
M_y \\
M_{xy}
\end{bmatrix} =
\begin{bmatrix}
B_{11} & B_{12} & B_{16} \\
B_{21} & B_{22} & B_{26} \\
B_{61} & B_{62} & B_{66}
\end{bmatrix}
\begin{bmatrix}
\varepsilon_{xx} \\
\varepsilon_{yy} \\
\gamma_{xy}
\end{bmatrix} +
\begin{bmatrix}
D_{11} & D_{12} & D_{16} \\
D_{21} & D_{22} & D_{26} \\
D_{61} & D_{62} & D_{66}
\end{bmatrix}
\begin{bmatrix}
\kappa_x \\
\kappa_y \\
\kappa_{xy}
\end{bmatrix}
\] (10)

2.3. Macroscale Level

On the macroscale or structural level, the mechanical response of structural members such as beams, plates, shells, etc. must be analysed taking into account possibilities to formulate structural theories of a different order.

2.3.1. Classical Laminate Beam Theory

Frequently, as engineers try to optimise the use of materials, they design composite beams made from two or more materials. The design rationale is quite straightforward. For bending loading, stiff, strong, heavy, or expensive material must be far away from the neutral axis at places where its effect will be greatest. The weaker, lighter, or less expensive material as composite laminates will be used in the part of the bridge beam under the moving load. Laminate beams with simple or double symmetric cross-sections are most important in engineering applications. The derivations are therefore limited to straight beams with simple symmetric constant cross-sections. The bending moments act in a plane of symmetry. Also, cross-sections consisting of partition walls and orthogonal to the plane of bending are considered. We consider elementary beam equations. The cross-section area can have various geometries but must be symmetric to the z-axis.

The known equations for the stress

\[
\sigma(x, z) = \bar{\varepsilon}(x)E(z) + z\kappa(x)E(z)
\] (12)

where \( E = E_{eff} \) is the effective elastic modulus in longitudinal direction.

The strains are deduced from the displacements

\[
\varepsilon(x, z) = \bar{\varepsilon}(x) + z\kappa(x)
\] (13)

with

\[
\varepsilon = \frac{\partial u}{\partial x}
\]

and

\[
\kappa = -\frac{\partial \psi}{\partial x}
\] (14)

Then strain \( \varepsilon \) can be written as

\[
\kappa = -\frac{\partial \psi}{\partial x}
\] (15)
The internal forces \( N, M \) can be obtained from

\[
N = \int_{-h/2}^{+h/2} E(z) dz \bar{e} + \int_{-h/2}^{+h/2} E(z) z dz \kappa
\]

\[
M = \int_{-h/2}^{+h/2} E(z) zdz \bar{e} + \int_{-h/2}^{+h/2} E(z) z^2 dz \kappa
\]

(16)

with stretching, coupling, and bending shear stiffness:

\[
A = b \int_{-h/2}^{+h/2} E(z) dz = b \sum_{n=1}^{N} n E h
\]

\[
B = b \int_{-h/2}^{+h/2} E(z) zdz = b \sum_{n=1}^{N} n E z^2 \sqrt{2}
\]

\[
D = b \int_{-h/2}^{+h/2} E(z) z^2 dz = b \sum_{n=1}^{N} n E z^3 \sqrt{3}
\]

(17)

where \( b \) is the beam width, \( n E \) is the effective elastic modulus in the longitudinal direction of \( n \)th layer and \( A = bA_{11}, B = bB_{11}, D = bD_{11} \).

The constitutive equation can be written in the condensed matrix form:

\[
\begin{pmatrix}
N \\
M
\end{pmatrix} =
\begin{pmatrix}
A & B \\
B & D
\end{pmatrix}
\begin{pmatrix}
\bar{e} \\
\kappa
\end{pmatrix}
\]

(18)

2.3.2. Shear Deformation Laminate Beam Theory

The classical laminate theory allows us to calculate the stresses and strains with high precision for very thin laminates except in a little extended region near the free edges. The validity of the classical theory has been established by comparing theoretical results with experimental tests and with more exact solutions based on the general equations of the linear anisotropic elasticity theory. If the width-to-thickness ratio is less than 20, the results derived from the classical theory show significant differences with the actual mechanical behaviour and the modelling must be improved. A first improvement is to the effect of shear deformation in the framework of a first-order displacement approach. A further improvement is possible by introducing correction factors for the transverse shear moduli.

The known equations for the stresses are the following:

\[
\sigma(x, z) = \bar{e}(x) E(z) + z \kappa(x) E(z)
\]

\[
\tau(x, z) = \gamma G(z)
\]

(19)

where \( E = E_{\text{eff}} \) and \( G = G_{\text{eff}} \) are the effective elastic moduli in longitudinal direction and transversal direction.

The strains are deduced from the displacements

\[
\varepsilon(x, z) = \bar{e}(x) + z \kappa(x)
\]

\[
\gamma(x, z) = \left( \frac{\partial \bar{w}(x)}{\partial x} - \psi(x) \right)
\]

(20)

with

\[
\bar{e} = \frac{\partial \bar{u}}{\partial x}
\]

and

\[
\kappa = -\frac{\partial \psi}{\partial x}
\]

(21)

Then strains can be written as

\[
\varepsilon = \frac{\partial \bar{w}}{\partial x} = \frac{\partial \bar{u}}{\partial x} - z \frac{\partial \psi}{\partial x}
\]

\[
\gamma = \frac{\partial \bar{w}}{\partial x} + \frac{\partial \bar{u}}{\partial x} = \frac{\partial \bar{w}}{\partial x} - \psi
\]

(22)
The stress $\sigma_x = \sigma$, varies linearly through a layer thickness and the stress $\tau_{xz} = \tau$ is constant through the thickness. There is no stress continuity through the laminate thickness but stress jumps from ply to ply at their interfaces depending on the reduced stiffness.

Internal forces can be written as

$$
N = \int_{-h/2}^{+h/2} E(z) dz \bar{\varepsilon} + \int_{-h/2}^{+h/2} E(z) dz \bar{\varepsilon}
$$

$$
M = \int_{-h/2}^{+h/2} E(z) dz \bar{\varepsilon} + \int_{-h/2}^{+h/2} E(z) z^2 dz \gamma
$$

$$
V = (k^*) \int_{-h/2}^{+h/2} E'(z) dz \gamma
$$

With stretching, coupling, and bending stiffnesses the same as in Equation (17). Transverse shear stiffness can be written as

$$
\bar{A} = b \int_{-h/2}^{+h/2} E'(z) dz = b \sum_{n=1}^{N} n E^{th} h
$$

where $n E^{th}$ is the effective elastic modulus in the transversal direction of $n$th layer.

The constitutive equation can by written in the condensed matrix form:

$$
\begin{pmatrix}
N \\
M \\
V
\end{pmatrix} =
\begin{pmatrix}
A & B & 0 \\
B & D & 0 \\
0 & 0 & -A
\end{pmatrix}
\begin{pmatrix}
\bar{\varepsilon} \\
\kappa \\
\gamma
\end{pmatrix}
$$

The shear stiffness values can be improved with help of shear correction factors. In this case, the part of the constitutive equation relating to the resultants $N, M$ is not modified. The other part relating to transverse shear resultants $V$ is modified by replacing the stiffness $\bar{A}$ by $k^* \bar{A}$.

The parameters $k^*$ is the shear correction factor. A very simply approach is to introduce a weighting function $f(z)$ for the distribution of the transverse shear stress through the thickness $h$.

Assume a parabolic function

$$
f(z) = \frac{5}{4} \left( 1 - \left( \frac{z}{h/2} \right)^2 \right)
$$

The transverse shear force is

$$
V_{xz} = \sum_{n=1}^{N} \int_{h}^{n \tau_{xz} f(z) dz} = \sum_{n=1}^{N} \int_{h}^{n \gamma_{xz} (1 - \left( \frac{z}{h/2} \right)^2) dj}
$$

The constitutive equation for shear force is

$$
V_{xz} = \bar{A} \gamma_{xz}
$$

For the components of $\bar{A}$ gilt

$$
\bar{A} = \frac{5}{4} \sum_{n=1}^{N} n E^{th} \left( \left( n z - n^{-1} z \right) - \frac{4}{3k^2} \left( n z^3 - n^{-1} z^3 \right) \right)
$$

This approach yields for the case of a single homogenous layer with $E^{th} = G_{eff}$ and shear correction factor $k^* = 5/6$ for the shear stiffness.

The first-order shear deformation theory yields mostly sufficiently accurate results for the displacements and for the in-plane stresses.
For a midplane symmetric laminated composite beam subjected to a lateral load $p_3$ and including transverse shear deformation:

$$D \frac{\partial^2 \psi}{\partial x^2} - k^3 A \left( \psi + \frac{\partial w}{\partial x} \right) - I \frac{\partial^2 \psi}{\partial t^2} = 0$$

$$k^3 A \left( \frac{\partial \psi}{\partial x} + \frac{\partial^2 w}{\partial x^2} \right) + p_3 = 0$$  \hspace{1cm} (30)

More often products and structures are subjected to vehicular dynamic loads. In the linear-elastic range, the dynamic effects can be divided into two categories: free vibrations and forced vibrations, and the latter can be further subdivided into one-time events or receiving loads. Free vibration problems are called eigenvalue problems. They are represented by homogeneous equations, for which nontrivial solutions only occur at certain characteristic values of a parameter, from which the natural frequencies are determined. In the general case of forced vibrations, the displacements, the rotations, and the transverse load $p_3$ are functions of $x$ and $t$. In-plane loading is not considered but in-plane displacement, rotary, and coupling inertia terms must be considered.

The governing equations for the calculation of natural frequencies of especially orthotropic beams are

$$D \frac{\partial^2 \psi}{\partial x^2} - k^3 A \left( \psi + \frac{\partial w}{\partial x} \right) - I \frac{\partial^2 \psi}{\partial t^2} = 0$$  \hspace{1cm} (31)

$$k^3 A \left( \frac{\partial \psi}{\partial x} + \frac{\partial^2 w}{\partial x^2} \right) - \rho_m h \frac{\partial^2 w}{\partial t^2} = 0$$  \hspace{1cm} (32)

For the force vibration analysis of laminate beam gilt:

$$k^3 A \left( \frac{\partial \psi}{\partial x} + \frac{\partial^2 w}{\partial x^2} \right) - \rho_m h \frac{\partial^2 w}{\partial t^2} + p_3(x, t) = 0$$  \hspace{1cm} (33)

where

$$\rho_m = b \sum_{n=1}^{N} n \rho \left( u_z - n^{-1} z \right)$$

and

$$I = b \frac{1}{3} \sum_{k=1}^{N} n \rho \left( u_z^3 - n^{-1} z^3 \right).$$  \hspace{1cm} (34)

The terms involving $\rho_m$ and $I$ are called translatory or rotatory inertia terms.

3. Bridge under Consideration, Discussion

The symmetric cross-ply laminated bridge, $(0/90)_{25}$, made of boron/epoxy is analysed next, in Figures 5–7. These are two separate bridges situated next to each other. The subject of the analysis is only one bridge. The geometric and material properties of this model are listed in Table 1.

![Figure 5. Simply supported bridge.](image-url)
3.1. A Computational Model of Vehicle and Bridge

To solve the task of the bridge response to the effects of moving loads due to a heavy truck, a two-dimensional (2D) model was adopted in this case [10]. The model of the vehicle is a 2D multi-body model with eight degrees of freedom, Figure 8.
Five degrees of freedom are mass (displacements \( r_i, i = 1, 2, 3, 4, 5 \)) and three are massless (displacements \( v_i, i = 3, 4, 5 \)). The displacement components corresponding to the degrees of freedom are arranged in the vector \( \{ r \} \):

\[
\{ r \} = [r_1(t), r_2(t), r_3(t), r_4(t), r_5(t), v_3(t), v_4(t), v_5(t)]^T
\]  

The system of equations describing the conditions of force equilibrium of the model has the form

\[
\{ F \} = \{ A \} \cdot \{ d(t) \}.
\]

The relationship between the displacement components \( \{ r(t) \} \) corresponding to the degrees of freedom and the deformations of the connecting members \( \{ d(t) \} \) is presented by a transposed static matrix \( [A]^T \) according to the relation

\[
\{ d(t) \} = [A]^T \cdot \{ r(t) \}.
\]

The dependence between the elastic forces in the connecting members (in terms of the action of mass objects on the connecting members) and their deformations is described by the equation

\[
\{ F_{re}(t) \} = [k] \cdot \{ d(t) \},
\]

where \( [k] \) is the stiffness matrix of the connecting members. The dependence of the damping forces on the strain rate \( \{ d(t) \} \) is

\[
\{ F_d(t) \} = [b] \cdot \{ d(t) \}.
\]

The resulting forces in the connecting members when acting on mass objects are

\[
\{ F_{CM}(t) \} = - (\{ F_{re}(t) \} + \{ F_d(t) \}).
\]

The sign (-) is a consequence of the principle of action and reaction. From the forces in the connecting members \( \{ F_{CM}(t) \} \), the static equivalents corresponding to the individual degrees of freedom \( \{ F_{DF}(t) \} \) are calculated according to the relation

\[
\{ F_{DF}(t) \} = [A] \cdot \{ F_{CM}(t) \}.
\]

To the forces corresponding to the individual degrees of freedom \( \{ F_{DF}(t) \} \) it is necessary to add the gravitational forces \( \{ F_G(t) \} \) and reactions at the point of contact \( \{ F_{RC}(t) \} \), which gives a complete vector of forces acting on the given computational model \( \{ F_R(t) \} \)

\[
\{ F_R(t) \} = \{ F_{DF}(t) \} + \{ F_G(t) \} + \{ F_{RC}(t) \}.
\]
The system of equations describing the conditions of force equilibrium of the model has the form

$$[m] \cdot \{\ddot{r}(t)\} = \{F_R(t)\}, \tag{42}$$

where $[m]$ is the mass matrix of the model. Derivations according to time $t$ are indicated by a dot above the sign of the dependent variable. System (42) is finally subdivided into equations of motion describing the vibration of the vehicle (43) and the equations for calculating the reactions at the contact points (44)

\begin{align*}
\ddot{r}_1(t) &= -\left\{b_1 \cdot [r_1(t) - a \cdot r_2(t) - r_3(t)] + b_2 \cdot [r_1(t) + b \cdot r_2(t) - r_4(t)] + k_1 \cdot [r_1(t) - a \cdot r_2(t) - r_3(t)] + \\
&+ k_2 \cdot [r_1(t) + b \cdot r_2(t) - r_4(t)]\right\}/m_1, \\
\ddot{r}_2(t) &= -\left\{-a \cdot b_1 \cdot [r_1(t) - a \cdot r_2(t) - r_3(t)] + b \cdot b_2 \cdot [r_1(t) + b \cdot r_2(t) - r_4(t)] - \\
&- a \cdot k_1 \cdot [r_1(t) - a \cdot r_2(t) - r_3(t)] + b \cdot k_2 \cdot [r_1(t) + b \cdot r_2(t) - r_4(t)]\right\}/I_{y1}, \\
\ddot{r}_3(t) &= -\left\{-b_1 \cdot [r_1(t) - a \cdot r_2(t) - r_3(t)] + b_3 \cdot [r_3(t) - v_3(t)] - k_1 \cdot [r_1(t) - a \cdot r_2(t) - r_3(t)] + \\
&+ k_3 \cdot [r_3(t) - v_3(t)]\right\}/m_2, \\
\ddot{r}_4(t) &= -\left\{-b_2 \cdot [r_1(t) + b \cdot r_2(t) - r_4(t)] + b_4 \cdot [r_4(t) - c \cdot r_5(t) - v_4(t)] + b_5 \cdot [r_4(t) + c \cdot r_5(t) - v_5(t)] - \\
&- k_2 \cdot [r_1(t) + b \cdot r_2(t) - r_4(t)] + k_4 \cdot [r_4(t) - c \cdot r_5(t) - v_4(t)] + k_5 \cdot [r_4(t) + c \cdot r_5(t) - v_5(t)]\right\}/m_3, \\
\ddot{r}_5(t) &= -\left\{-c \cdot b_1 \cdot [r_4(t) - c \cdot r_5(t) - v_4(t)] + c \cdot b_5 \cdot [r_4(t) + c \cdot r_5(t) - v_5(t)] - \\
&- c \cdot k_4 \cdot [r_4(t) - c \cdot r_5(t) - v_4(t)] + c \cdot k_5 \cdot [r_4(t) + c \cdot r_5(t) - v_5(t)]\right\}/I_{y3},
\end{align*}

\begin{align*}
F_{RCA}(t) &= G_3 - k_3 \cdot [r_3(t) - v_3(t)] - b_3 \cdot [r_3(t) - v_3(t)] = \\
&= g \cdot (m_1 \cdot b/s + n_2) - k_3 \cdot [r_3(t) - v_3(t)] - b_3 \cdot [r_3(t) - v_3(t)], \\
F_{RCA}(t) &= G_4 - k_4 \cdot [r_4(t) - c \cdot r_5(t) - v_4(t)] - b_4 \cdot [r_4(t) - c \cdot r_5(t) - v_4(t)] = \\
&= 0.5 \cdot g \cdot (m_1 \cdot a/s + m_3) - k_4 \cdot [r_4(t) - c \cdot r_5(t) - v_4(t)] - b_4 \cdot [r_4(t) - c \cdot r_5(t) - v_4(t)], \\
F_{RCS}(t) &= G_5 - k_5 \cdot [r_5(t) + c \cdot r_5(t) - v_5(t)] - b_5 \cdot [r_4(t) + c \cdot r_5(t) - v_5(t)] = \\
&= 0.5 \cdot g \cdot (m_1 \cdot a/s + m_3) - k_5 \cdot [r_4(t) + c \cdot r_5(t) - v_5(t)] - b_5 \cdot [r_4(t) + c \cdot r_5(t) - v_5(t)].
\end{align*}

The bridge is modelled as simple supported Bernoulli–Euler beam with continuously distributed mass. The equation of motion has the form

$$E \cdot I \frac{d^4y(x, t)}{dx^4} + \mu \frac{d^2y(x, t)}{dt^2} + 2 \cdot \mu \cdot \omega_b \frac{dy(x, t)}{dt} = p(x, t) \tag{45}$$

where $E$ is modulus of elasticity, $I$ is quadratic moment of cross section, $\mu$ is mass intensity per meter of length, $\omega_b$ is angular damping frequency, $y(x, t)$ is dynamic bending line, and $p(x, t)$ is the intensity of the continuous distributed load. Equation (45) is a partial differential equation. Since the equations of motion of the vehicle are ordinary differential equations, it is also appropriate to transform the bridge equation of motion into an ordinary differential equation. This can be performed by assuming the shape of the bending line of the bridge $y_0(x)$

$$y(x, t) = q(t) \cdot y_0(x) = q(t) \cdot \sin \frac{\pi \cdot x}{L}. \tag{46}$$

The proportionality coefficient $q(t)$ has the meaning of the generalised Lagrange coordinate and $L$ is the span of the bridge. Substituting assumption (46) into equation (45) produces

$$\left\{\ddot{q}(t) \cdot \mu + \ddot{q}(t) \cdot 2 \cdot \mu \cdot \omega_b + q(t) \cdot E \cdot I \frac{d^4y(x, t)}{dx^4}\right\} \sin \frac{\pi \cdot x}{L} = p(x, t). \tag{47}$$

In the case of motion of discrete forces $F_i$, the continuously distributed load $p(x, t)$ can be expressed by the use of Dirac function [8] in the form

$$p(x, t) = \sum_{i=1}^{\infty} \varepsilon_j \cdot \delta(x - x_j) \cdot F_i(t) = \sum_{i=1}^{\infty} \sum_{i=1}^{\infty} p_{n_i}(t) \cdot \sin \frac{n \cdot \pi \cdot x}{L}, \tag{48}$$

where

$$p_{n_i}(t) = \frac{2}{L} \int_0^1 p_j(x, t) \cdot \sin \frac{n \cdot \pi \cdot x}{L} \, dx \cdot \frac{2}{L} \varepsilon_j \cdot F_i(t) \cdot \sin \frac{n \cdot \pi \cdot x_j}{L}. \tag{49}$$
Then
\[
p(x, t) = \sum_{j} \sum_{n=1}^{\infty} p_{n,j}(t) \cdot \sin \frac{n \pi x}{L} = \sum_{j} \sum_{n=1}^{\infty} 2 \eta_j \cdot F_j(t) \cdot \sin \frac{n \pi x}{L} \cdot \sin \frac{n \pi y}{L}
\]
\[
= \sum_{j} \sum_{n=1}^{\infty} \frac{2}{L} \eta_j \cdot F_{int,j}(t) \cdot \sin \frac{n \pi y}{L} \cdot \sin \frac{n \pi x}{L}.
\]

If we take into account only the first member of the series, the expression takes the form
\[
p(x, t) = \frac{2}{L} \sin \frac{\pi x}{L} \sum_j \eta_j \cdot F_j(t) \cdot \sin \frac{\pi x}{L}.
\]

If the force \(F_j\) is already on the beam, then \(\eta_j = 1\), if \(F_j\) is outside the beam, \(\eta_j = 0\). The time \(t = 0\) corresponds to the input of the first axle on the beam. If we are looking for a response only in the middle of the bridge span, \(x = L/2\), then \(\sin(\pi x/L) = 1\), and the equation of motion of the bridge takes the form
\[
\ddot{q}(t) + \mu \dot{q}(t) + 2 \mu \omega_b + q(t) \cdot E \cdot I \cdot \frac{\pi^4}{L^4} = \frac{2}{L} \sum_j \eta_j \cdot F_j(t) \cdot \sin \frac{\pi x}{L}.
\]

It is possible to work with the unevenness of the road \(u(t)\) and define the resulting profile of the road surface as
\[
v(x, t) = y(x, t) + u(t).
\]

3.2. Results of Numerical Solution

The numerical solution of the equations of motion was performed in the environment of MATLAB system [12]. The fourth order Runge–Kutta method was used (ode45 procedure). The second order differential equations were transformed to the first order equations by the following substitution
\[
\begin{align*}
\eta_1(t) &= y_1(t), & \eta_2(t) &= y_2(t), & \eta_3(t) &= y_3(t), & \eta_4(t) &= y_4(t), & \eta_5(t) &= y_5(t), & \eta_6(t) &= y_6(t), & \eta_7(t) &= y_7(t), & \eta_8(t) &= y_8(t), & \eta_9(t) &= y_9(t), & \eta_{10}(t) &= y_{10}(t), & \eta_{11}(t) &= y_{11}(t), & \eta_{12}(t) &= y_{12}(t),
\end{align*}
\]

The subject of the solution is then the set of 12 the first order differential equations for unknown functions \(y_i(t)\), \(i = 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12\) in the form
\[
\begin{align*}
\dot{y}_1(t) &= y_2(t), & \dot{y}_2(t) &= \dot{y}_1(t), & \dot{y}_3(t) &= \dot{y}_4(t), & \dot{y}_4(t) &= \dot{y}_5(t), & \dot{y}_5(t) &= y_6(t), & \dot{y}_6(t) &= \dot{y}_7(t), & \dot{y}_7(t) &= \dot{y}_8(t), & \dot{y}_8(t) &= \dot{y}_9(t), & \dot{y}_9(t) &= \dot{y}_{10}(t), & \dot{y}_{10}(t) &= \dot{y}_{11}(t), & \dot{y}_{11}(t) &= \dot{y}_{12}(t), & \dot{y}_{12}(t) &= \ddot{q}(t).
\end{align*}
\]

The subject of numerical analysis are the time dependences of dynamic deflections in the middle of the bridge span. As is known, all kinematic quantities of the bridge response depend on the speed of movement of the vehicle [23]. Therefore, in the first step, the dependence of the dynamic factor \(\delta\) of the bridge on the speed of movement of the vehicle was calculated in Figure 9. A smooth bridge surface and zero initial conditions on both the vehicle and the bridge are assumed:
\[
r_i(0) = \dot{r}_i(0) = 0, \ i = 1, 2, 3, 4, 5, \ q(0) = \ddot{q}(0) = 0.
\]

The vehicle parameters are:
\[
m_1 = 22,950 \text{ kg, } m_2 = 2910 \text{ kg, } m_3 = 2140 \text{ kg, } I_{x1} = 62,298 \text{ kg} \cdot \text{m}^2, \ I_{y3} = 932 \text{ kg} \cdot \text{m}^2,
\]
\[
k_1 = 287,433 \text{ N} \cdot \text{m}, \ k_2 = 1,522,512 \text{ N} \cdot \text{m}, \ k_3 = 2,550,600 \text{ N} \cdot \text{m}, \ k_4 = k_5 = 5,022,720 \text{ N} \cdot \text{m},
\]
\[
b_1 = 19,228 \text{ kg} \cdot \text{s}, \ b_2 = 260,197 \text{ kg} \cdot \text{s}, \ b_3 = 2746 \text{ kg} \cdot \text{s}, \ b_4 = b_5 = 5494 \text{ kg} \cdot \text{s},
\]
\[
a = 3.135 \text{ m}, \ b = 1.075 \text{ m}, \ c = 0.66 \text{ m}, \ s = 4.21 \text{ m}.
\]

The bridge parameters are:
\[
L = 37 \text{ m, } \mu = 6642 \text{ kg} \cdot \text{m}^3, \ I = 0.23186 \text{ m}^4, E = 1.15e11 \text{ Pa, } \omega_b = 0.23321 \text{ rad} / \text{s},
\]
Maximum static deflection from the vehicle \(y_9 = 9.815068 \text{ mm}\).
The dependence $\delta(V)$ is a curve that has many local maxima and spikes [24]. The position of the spikes is related to the discontinuous course of the function indicating the position of the vehicle on the bridge at the moment when the maximum deflection occurs. Figure 10 shows the position of the vehicle centre of gravity on the bridge (in dimensionless form $x_C/L$) at the moment when the maximum deflection occurs depending on the speed of the vehicle $V$. For practical purposes, it is appropriate to define an envelope curve, for example in the shape

$$envelope = 1/(1 - 0.5 \cdot \alpha) \quad (57)$$

where $\alpha$ is dimensionless speed parameter defined as

$$\alpha = T_{(1)} / (2T_s). \quad (58)$$

$T_{(1)}$ is the period of bridge vibration in the first natural mode and $T_s$ is the time of stay of the vehicle axle on the bridge.

In the second step, the calculation of the time response of the bridge for the characteristic speeds of the vehicle was performed. The speeds 38 km/h, 51 km/h, and 95 km/h correspond to the local maxima of the function $\delta(V)$ and the speeds 43.1 km/h, 62.7 km/h, and 123.2 km/h correspond to the spikes. In this analysis, it was assumed that the vehicle enters the bridge already vibrant. The initial conditions for the vehicle are as follows:

$r_1(0) = -0.02$ m, $r_2(0) = -0.03$ rad, $r_3(0) = -0.002$ m, $r_4(0) = -0.003$ m, $r_5(0) = 0$ m, $\dot{r}_i(0) = 0$, $i = 1, 2, 3, 4, 5$.

Figure 11 shows the time courses of the vertical deflections in the middle of the bridge span for speeds 38, 51, and 95 km/h, and Figure 12 for speeds 43.1, 62.7, and 123.2 km/h.
Figure 11. Time courses of the vertical deflections in the middle of the bridge span for speeds 38, 51, and 95 km/h.

Figure 12. Time courses of the vertical deflections in the middle of the bridge span for speeds 43.1, 62.7, and 123.2 km/h.
The maximum bridge deflections and dynamic factors for individual speeds are summarised in Table 2.

### Table 2. Maximum bridge deflections and dynamic factors for individual speeds.

| Speed V (km/h) | $t_{\text{max}}$ (s) | Max. Dynamic Deflection $v_{\text{max}}$ (mm) | Dynamic Factor $\delta$ |
|----------------|-------------------------|---------------------------------------------|------------------------|
| 38             | 2.0310                  | 9.9627                                      | 1.0150                 |
| 51             | 1.5432                  | 10.1018                                     | 1.0292                 |
| 95             | 0.8544                  | 11.0073                                     | 1.1214                 |
| 43.1           | 1.6296                  | 9.9250                                      | 1.0112                 |
| 62.7           | 1.0705                  | 9.8174                                      | 1.0002                 |
| 123.2          | 0.7711                  | 10.4482                                     | 1.0645                 |

### 4. Conclusions

The use of fibre-reinforced polymer composite materials in modern engineering applications has been increasing rapidly. Bridges and aerospace structures are a couple of examples of their application. Steel bridges are replaced by composite materials due to their superior qualities, such as a higher strength-to-weight ratio. Bridge structures are constantly being exposed to various types of loads. The major loads that influence the life of a bridge are dynamic moving loads.

For the forced vibration analysis of laminated polymer composite beams under the effect of moving loads, it is advantageous to use the MATLAB software system. To solve equations of motion, the Runge–Kutta–Fehlberg methods can be used (ode45 solver).

The bridge response to the effects of moving loads is influenced by many factors. The most important of these can be considered the speed of the vehicle. It only makes sense to talk about the influence of all other parameters in connection with the specific speed of the vehicle. If the deflections in the middle of the bridge span are analysed, it is advantageous to work with dimensionless values in the form of dynamic magnification factors $\delta$. The dependence of the dynamic factor on the speed of the vehicle $\delta(V)$ is a curve that has many local maxima and spikes. Its shape depends on the type of vehicle used in the analysis. For practical reasons, it is good to define the envelope of amplitudes.

Therefore, in this case, the dynamic magnification factors for the dynamic analysis of composite beams were computed. The maximum dynamic magnification factor occurs at the velocity of 95 km/h.

The ply orientation influences the dynamic behaviour of a beam subjected to a moving load. Based on these results, a designer can choose the right ply orientations to control the dynamic behaviour of laminated beams.

We are still working on research which considers the classic conventional materials, the cross-section of a bridge made of steel girders and a concrete bridge deck. To solve this task of the bridge response to the effects of moving loads due to a heavy truck, a 1D model was adopted. We obtain the maximum difference between the dynamic and static deflection in the middle of the bridge of 21.9%. By replacing conventional materials with laminated composite, we obtained the maximum difference between the dynamic and static deflection in the middle of the bridge of 16.11%. From this point of view, the use of FRP materials in bridge structures is still in its infancy, and there are very clear indications that it will be an excellent choice for a multitude of projects on bridges in the future.
