Abstract

Let $n \geq 3$. In this paper, we study the problem of whether a given finite group $G$ embeds in a quotient of the form $B_n/\Gamma_k(P_n)$, where $B_n$ is the $n$-string Artin braid group, $k \in \{2,3\}$, and $\{\Gamma_l(P_n)\}_{l \in \mathbb{N}}$ is the lower central series of the $n$-string pure braid group $P_n$. Previous results show that a necessary condition for such an embedding to exist is that $|G|$ is odd (resp. is relatively prime with $6$) if $k = 2$ (resp. $k = 3$). We show that any finite group $G$ of odd order (resp. of order relatively prime with $6$) embeds in $B_{|G|}/\Gamma_2(P_{|G|})$ (resp. in $B_{|G|}/\Gamma_3(P_{|G|})$), where $|G|$ denotes the order of $G$. The result in the case of $B_{|G|}/\Gamma_2(P_{|G|})$ has been proved independently by Beck and Marin. One may then ask whether $G$ embeds in a quotient of the form $B_n/\Gamma_k(P_n)$, where $n < |G|$ and $k \in \{2,3\}$. If $G$ is of the form $\mathbb{Z}_{p^r} \rtimes \mathbb{Z}_d$, where the action $\theta$ is injective, $p$ is an odd prime (resp. $p \geq 5$ is prime) and $d$ is odd (resp. $d$ is relatively prime with $6$) and divides $p - 1$, we show that $G$ embeds in $B_{p^r}/\Gamma_2(P_{p^r})$ (resp. in $B_{p^r}/\Gamma_3(P_{p^r})$). In the case $k = 2$, this extends a result of Marin concerning the embedding of the Frobenius groups in $B_n/\Gamma_2(P_n)$, and is a special case of another result of Beck and

Marin. Finally, we construct an explicit embedding in $B_9/\Gamma_2(P_9)$ of the two non-Abelian groups of order 27, namely the semi-direct product $\mathbb{Z}_9 \rtimes \mathbb{Z}_3$, where the action is given by multiplication by 4, and the Heisenberg group mod 3.

1 Introduction

If $n \in \mathbb{N}$, let $B_n$ denote the (Artin) braid group on $n$ strings. It is well known that $B_n$ admits a presentation with generators $\sigma_1, \ldots, \sigma_{n-1}$ that are subject to the relations $\sigma_i \sigma_j = \sigma_j \sigma_i$ for all $1 \leq i < j \leq n - 1$ for which $|i - j| \geq 2$, and $\sigma_i \sigma_{i+1} \sigma_i = \sigma_{i+1} \sigma_i \sigma_{i+1}$ for all $1 \leq i \leq n - 2$. Let $\sigma : B_n \rightarrow S_n$ denote the surjective homomorphism onto the symmetric group $S_n$ defined by $\sigma(\sigma_i) = (i, i + 1)$ for all $1 \leq i \leq n - 1$. The pure braid group $P_n$ on $n$ strings is defined to be the kernel of $\sigma$, from which we obtain the following short exact sequence:

$$1 \longrightarrow P_n \longrightarrow B_n \xrightarrow{\sigma} S_n \longrightarrow 1.$$  \hspace{1cm} (1)

If $G$ is a group, recall that its lower central series $\{\Gamma_k(G)\}_{k \in \mathbb{N}}$ is defined by $\Gamma_1(G) = G$, and $\Gamma_k(G) = \left[\Gamma_{k-1}(G), G\right]$ for all $k \geq 2$ (if $H$ and $K$ are subgroups of $G$, $[H, K]$ is defined to be the subgroup of $G$ generated by the commutators of the form $[h, k] = hkh^{-1}k^{-1}$, where $h \in H$ and $k \in K$). Note that $\Gamma_2(G)$ is the commutator subgroup of $G$, and that $\Gamma_k(G)$ is a normal subgroup of $G$ for all $k \in \mathbb{N}$. In our setting, since $P_n$ is normal in $B_n$, it follows that $\Gamma_k(P_n)$ is also normal in $B_n$, and the extension (1) induces the following short exact sequence:

$$1 \longrightarrow P_n/\Gamma_k(P_n) \longrightarrow B_n/\Gamma_k(P_n) \xrightarrow{\overline{\sigma}} S_n \longrightarrow 1,$$  \hspace{1cm} (2)

obtained by taking the quotient of $P_n$ and $B_n$ by $\Gamma_k(P_n)$. It follows from results of Falk and Randell [FR] and Kohno [K] that the kernel of (2) is torsion free (see Proposition 5 for more information). The quotient groups of the form $B_n/\Gamma_k(P_n)$ have been the focus of several recent papers. First, the quotient $B_n/\Gamma_2(P_n)$ belongs to a family of groups known as enhanced symmetric groups [M1, page 201] that were analysed in [T]. Secondly, in their study of pseudo-symmetric braided categories, Panaite and Staic showed that this quotient is isomorphic to the quotient of $B_n$ by the normal closure of the set $\{\sigma_i \sigma_{i+1}^{-1} \sigma_i \sigma_{i+1}^{-1} \sigma_i \sigma_{i+1}^{-1} | i = 1, 2, \ldots, n - 2\}$ [PS]. Thirdly, in [GGO1], we showed that $B_n/\Gamma_2(P_n)$ is a crystallographic group, and that up to isomorphism, its finite Abelian subgroups are the Abelian subgroups of $S_n$ of odd order. In particular, the torsion of $B_n/\Gamma_2(P_n)$ is the odd torsion of $S_n$. We also gave an explicit embedding in $B_7/\Gamma_2(P_7)$ of the Frobenius group $\mathbb{Z}_7 \rtimes \mathbb{Z}_3$ of order 21, which is the smallest finite non-Abelian group of odd order. As far as we know, this is the first example of a finite non-Abelian group that embeds in a quotient of the form $B_n/\Gamma_2(P_n)$. Almost all of the results of [GGO1] were subsequently extended to the generalised braid groups associated to an arbitrary complex reflection group by Marin [M2]. If $p > 3$ is a prime number for which $p \equiv 3 \mod 4$, he showed that the Frobenius group $\mathbb{Z}_p \rtimes \mathbb{Z}_{(p-1)/2}$ embeds in $B_{p}/\Gamma_2(P_p)$. Observe that this group cannot be embedded in $B_n/\Gamma_2(P_n)$ for any $n < p$, since $\mathbb{Z}_p$ cannot be embedded in $S_n$ in this case. In another direction, the authors studied some aspects of the quotient $B_n/\Gamma_k(P_n)$ for all $n, k \geq 3$, and proved that it is an almost-crystallographic group [GGO2]. For the case $k = 3$, it was shown that
the torsion of $B_n/\Gamma_3(P_n)$ is the torsion of $S_n$ that is relatively prime with 6. For future reference, we summarise some of these results in the following theorem.

**Theorem 1** ([GGO1, Corollary 4], [GGO2, Theorems 2 and 3]). Let $n \geq 3$.

(a) The torsion of the quotient $B_n/\Gamma_2(P_n)$ is equal to the odd torsion of $S_n$.

(b) The group $B_n/\Gamma_3(P_n)$ has no elements of order 2 or 3, and if $m \in \mathbb{N}$ is relatively prime with 6 then $B_n/\Gamma_3(P_n)$ possesses elements of order $m$ if and only if $S_n$ does.

Almost nothing is known about the torsion and the finite subgroups of $B_n/\Gamma_k(P_n)$ in the case where $k > 3$.

Suppose that $n \geq 3$ and $k \geq 2$. The results of [GGO1, GGO2, M2] lead to a number of interesting problems involving the quotients $B_n/\Gamma_k(P_n)$. Given a finite group $G$, a natural question in our setting is whether it can be embedded in some $B_n/\Gamma_k(P_n)$. In order to formulate some of these problems, we introduce the following notation. Let $|G|$ denote the order of $G$, let $m(G)$ denote the least positive integer $r$ for which $G$ embeds in the symmetric group $S_r$, and if $k \geq 2$, let $\ell_k(G)$ denote the least positive integer $s$, if such an integer exists, for which $G$ embeds in the group $B_s/\Gamma_k(P_s)$. The integer $\ell_k(G)$ is not always defined. For example, if $G$ is of even order, Theorem 1(a) implies that $G$ does not embed in any group of the form $B_n/\Gamma_k(P_n)$. However, if $\ell_k(G)$ is defined, then $m(G) \leq \ell_k(G)$ using (2) and the fact that $P_n/\Gamma_k(P_n)$ is torsion free.

The main aim of this paper is to study the embedding of finite groups in the two quotients $B_n/\Gamma_k(P_n)$, where $k \in \{2,3\}$. In Section 2, we start by recalling some results from [GGO1, GGO2] about the action of $S_n$ on certain bases of the free Abelian groups $P_n/\Gamma_2(P_n)$ and $\Gamma_2(P_n)/\Gamma_3(P_n)$, which we use to obtain information about the cycle structure of elements of $S_n$ that fix elements of these bases. In Proposition 7, using cohomological arguments, we show that a short exact sequence splits if its quotient is a finite group $G$ and its kernel is a free $\mathbb{Z}[G]$-module. This provides a fundamental tool for embedding $G$ in our quotients. In Section 3, we prove the following result.

**Theorem 2.** Let $G$ be a finite group, and let $k \in \{2,3\}$. Then the group $G$ embeds in $B_{|G|}/\Gamma_k(P_{|G|})$ if and only if $\gcd(|G|, k!) = 1$.

The statement of Theorem 2 has been proved independently by Beck and Marin in the case $k = 2$ [BM] using different methods within the setting of real reflection groups. This result may be viewed as a Cayley-type result for $B_n/\Gamma_k(P_n)$ since the proof makes use of the embedding of $G$ in the symmetric group $S_{|G|}$, as well as Proposition 8 that provides sufficient conditions on the fixed points in the image of an embedding of $G$ in $S_m$ for $G$ to embed in $B_n/\Gamma_k(P_n)$. If $\gcd(|G|, k!) = 1$, it follows from this theorem that $\ell_k(G) \leq |G|$ by Theorem 2, from which we obtain:

$$m(G) \leq \ell_k(G) \leq |G|. \quad (3)$$

The analysis of the inequalities of (3) is itself an interesting problem. Using Theorem 1, if $G$ is a cyclic group of prime order at least 5 and $k$ is equal to either 2 or 3 then $m(G) = \ell_k(G) = |G|$. In [BM, Corollary 13], Beck and Marin show that $m(G) = \ell_2(G)$ for any finite group of odd order in a broader setting. This result may also be obtained by applying [BM, Corollary 7] to [GGO1, Corollary 4 and its proof]. We do not currently know whether there exist groups for which $m(G) < \ell_3(G)$. 

3
In Section 4, we study the embedding of certain finite groups in \( B_n/\Gamma_k(P_n) \), where \( k \in \{2, 3\} \). In the case \( k = 2 \), our results are special cases of [BM, Corollary 13], but the methods that we use are rather different from those of [BM], and they are also valid for the case \( k = 3 \). In Section 4.1, we consider certain semi-direct products of the form \( \mathbb{Z}_n \rtimes \mathbb{Z}_m \) for which the action \( \theta \) is injective, and we analyse their possible embedding in \( B_n/\Gamma_k(P_n) \). Our main result in this direction is the following.

**Theorem 3.** Let \( m, n \geq 3 \), let \( G = \mathbb{Z}_n \rtimes \mathbb{Z}_m \), where \( \theta: \mathbb{Z}_m \rightarrow \mathbb{Z}_n \) is the associated action, and let \( 1 \leq t < n \) be such that \( \theta(1_m) \) is multiplication by \( t \) in \( \mathbb{Z}_n \). Assume that \( \gcd(t^l - 1, n) = 1 \) for all \( 1 \leq l \leq m - 1 \). If \( mn \) is odd (resp. \( \gcd(mn, 6) = 1 \)) then \( G \) embeds in \( B_n/\Gamma_2(P_n) \) (resp. in \( B_n/\Gamma_3(P_n) \)).

Using Lemma 11(a), we remark that the hypotheses of Theorem 3 imply that the action \( \theta: \mathbb{Z}_m \rightarrow \text{Aut}(\mathbb{Z}_n) \) is injective. As an application of this theorem, we obtain the following corollary.

**Corollary 4.** Let \( p \) be an odd prime, let \( p - 1 = 2d \), where \( d \) is odd, let \( d_1 \) be a divisor of \( d \), and let \( G \) be a group of the form \( \mathbb{Z}_p^r \rtimes \mathbb{Z}_{d_1} \), where \( \theta: \mathbb{Z}_{d_1} \rightarrow \text{Aut}(\mathbb{Z}_p^r) \) is injective.

(a) If \( p \geq 3 \) then \( G \) embeds in \( B_{p^r}/\Gamma_2(P_{p^r}) \).
(b) If \( p \geq 5 \) and \( d_1 \) satisfies \( \gcd(d_1, 3) = 1 \) then \( G \) embeds in \( B_{p^r}/\Gamma_3(P_{p^r}) \).

Since the group \( \mathbb{Z}_p^r \) cannot be embedded in \( S_m \) for any \( m < p^r \), the groups of Corollary 4 satisfy \( m(G) = \ell_k(G) = p^r \), where \( k \in \{2, 3\} \), so the results of this corollary are sharp in this sense, and are coherent with those of [BM, Corollary 13] in the case \( k = 2 \). Further, the groups that appear in [M2, Corollary 3.11] correspond to the case of where \( r = 1 \), \( p \equiv 3 \mod 4 \), and \( d_1 = (p - 1)/2 \) is odd. Hence Corollary 4 generalises Marin’s result to the case where \( p \) is any odd prime and \( d_1 \) is the greatest odd divisor of \( p - 1 \), and more generally, in the case \( k = 2 \), the family of groups obtained in Theorem 3 extends even further that of the Frobenius groups of [M2, Corollary 3.11].

At the end of the paper, in Section 4.2, we give explicit embeddings of the two non-Abelian groups of order 27 in \( B_9/\Gamma_2(P_9) \). Neither of these groups satisfies the hypotheses of Theorem 3. The fact that they embed in \( B_9/\Gamma_2(P_9) \) follows from the more general result of [BM, Corollary 13], but our approach is different to that of [BM]. Within our framework, it is natural to study these two groups, first because with the exception of the Frobenius group of order 21 analysed in [GGO1], they are the smallest non-Abelian groups of odd order, and secondly because they are of order 27, so are related to the discussion in Section 4.1 on groups whose order is a prime power. The direct embedding of these groups in \( B_9/\Gamma_2(P_9) \) is computationally difficult due to the fact that the kernel \( P_9/\Gamma_2(P_9) \) of (2) is of rank 36, but we get round this problem by first considering an embedding in a quotient where the corresponding kernel is free Abelian of rank 9, and then by applying Proposition 7. We believe that this technique will prove to be useful for other groups.

If \( n \geq 3 \), it follows from [BM, Corollary 13] that the isomorphism classes of the finite subgroups of \( B_n/\Gamma_2(P_n) \) are in bijection with those of the subgroups of \( S_n \) of odd order. The study of the finite non-cyclic subgroups of \( B_n/\Gamma_3(P_n) \) constitutes work in progress.

The third author was initially supported by a project grant nº 151161/2013-5 from CNPq. We would also like to thank Vincent Beck and Ivan Marin for sharing their results with us.

2 Preliminaries

In this section, we recall several results concerning the torsion of the groups $B_n/\Gamma_k(P_n)$, where $k \in \{2,3\}$, as well as some group-cohomological facts from [Br] that will be used in this paper. We first state the following result from [GGO2] that we will require.

**Proposition 5.** [GGO2, Lemma 11]

(a) Let $n, k \geq 2$. Then the group $P_n/\Gamma_k(P_n)$ is torsion free.
(b) Let $n \geq 3$, let $k \geq 1$, and let $G$ be a finite group. If $B_n/\Gamma_k(P_n)$ possesses a (normal) subgroup isomorphic to $G$ then $B_n/\Gamma_1(P_n)$ possesses a (normal) subgroup isomorphic to $G$. In particular, if $p$ is prime, and if $B_n/\Gamma_1(P_n)$ has no p-torsion then $B_n/\Gamma_k(P_n)$ has no p-torsion.

Note that the first part of Proposition 5 follows from papers by Falk and Randell [FR, Theorem 4.2] and Kohno [K, Theorem 4.5] who proved independently that for all $n \geq 2$ and $k \geq 1$, the group $\Gamma_k(P_n)/\Gamma_{k+1}(P_n)$ is free Abelian of finite rank, the rank being related to the Poincaré polynomial of certain hyperplane complements.

It is well known that a set of generators for $P_n$ is given by the set \{${\{A_{i,j}\}_{1 \leq i < j \leq n}}$\} [H]. If $j > i$ then we take $A_{j,i} = A_{i,j}$. By abuse of notation, for $k \geq 2$ and $1 \leq i < j \leq n$, we also denote the image of $A_{i,j}$ under the canonical projection $P_n \rightarrow P_n/\Gamma_k(P_n)$ by $A_{i,j}$. The groups $P_n/\Gamma_2(P_n)$ and $\Gamma_2(P_n)/\Gamma_3(P_n)$ are free Abelian groups of finite rank $n(n-1)/2$ and $n(n-1)(n-2)/6$ respectively [FR, Theorem 4.2]. By [GGO1, Section 3, p. 399] (resp. [GGO2, equation (17)]), a basis for $P_n/\Gamma_2(P_n)$ (resp. $\Gamma_2(P_n)/\Gamma_3(P_n)$) is given by:

$$B = \{A_{i,j} \mid 1 \leq i < j \leq n\} \quad \text{(resp. by } B' = \{a_{i,j} \mid 1 \leq i < j \leq k \leq n\}),$$

where $\alpha_{i,j,k} = [A_{i,j}, A_{j,k}]$. If $\tau \in S_n$, $A_{i,j} \in B$ and $\alpha_{i,j,k} \in B'$ then by [GGO1, Proposition 12] and [GGO2, equation (8)], we have:

$$\tau \cdot A_{i,j} = A_{\tau^{-1}(i),\tau^{-1}(j)} \quad \text{and} \quad \tau \cdot \alpha_{i,j,k} = \tau \cdot [A_{i,j}, A_{j,k}] = [A_{\tau^{-1}(i),\tau^{-1}(j)}, A_{\tau^{-1}(j),\tau^{-1}(k)}].$$

The following lemma implies that $S_n$ acts on $B$ and $B'$ respectively, where $B' = B'' \cup B''^{-1}$. In each case, the nature of the action gives rise by linearity to an action of $S_n$ on the whole group. We also obtain some information about the stabilisers of the elements of $B$ and $B'$. This will play a crucial rôle in the proof of Proposition 8.

**Lemma 6.** Let $n \geq 2$, and let $\tau \in S_n$.

(a) Let $A_{i,j}$ be an element of the basis $B$ of $P_n/\Gamma_2(P_n)$, where $1 \leq i < j \leq n$. Then the element $\tau \cdot A_{i,j}$ given by the action of $S_n$ on $P_n/\Gamma_2(P_n)$ belongs to $B$. Further, if $\tau \cdot A_{i,j} = A_{i,j}$ then the cycle decomposition of $\tau$ either contains a transposition, or at least two fixed elements.
(b) Let \( \alpha_{i,j,k} \) be an element of the basis \( \mathcal{B} \) of \( \Gamma_2(P_n) / \Gamma_3(P_n) \), where \( 1 \leq i < j < k \leq n \). Then the element \( \tau \cdot \alpha_{i,j,k} \) given by the action of \( S_n \) on \( \Gamma_2(P_n) / \Gamma_3(P_n) \) belongs to \( \widetilde{\mathcal{B}}' \). Further, if \( \tau \cdot \alpha_{i,j,k} \in \left\{ \alpha_{i,j,k}, \alpha_{i,j,k}^{-1} \right\} \) then the cycle decomposition of \( \tau \) contains either a transposition, or a 3-cycle, or at least three fixed elements.

**Proof.**

(a) The first part follows from (5). If \( 1 \leq i < j \leq n \) and \( \tau \in S_n \) are such that \( \tau \cdot A_{i,j} = A_{i,j} \) then \( \tau(\{i,j\}) = \{\tau(i), \tau(j)\} = \{i,j\} \), which implies the second part of the statement.

(b) The first part is a consequence of [GGO2, equation (16)]. Now suppose that \( \tau \cdot \alpha_{i,j,k} \in \left\{ \alpha_{i,j,k}, \alpha_{i,j,k}^{-1} \right\} \), where \( 1 \leq i < j < k \leq n \) and \( \tau \in S_n \). By [GGO2, equation (18)], we have \( \tau(\{i,j,k\}) = \{\tau(i), \tau(j), \tau(k)\} = \{i,j,k\} \), from which we deduce the second part. \( \square \)

Lemma 6 implies that if \( G = S_n \) then \( \mathcal{B} \) and \( \widetilde{\mathcal{B}}' \) are \( G \)-sets, and the action of \( G \) on each of these sets extends to a \( \mathbb{Z} \)-linear action of \( G \) on the free \( \mathbb{Z} \)-modules \( \mathbb{Z}\mathcal{B} \) and \( \mathbb{Z}\mathcal{B}' \) respectively, with respect to the embedding of \( \widetilde{\mathcal{B}}' \) in \( \mathbb{Z}\mathcal{B}' \) given by \( \alpha_{i,j,k} \mapsto \alpha_{i,j,k} \) and \( \alpha_{i,j,k}^{-1} \mapsto (-1) \cdot \alpha_{i,j,k} \), the underlying free Abelian groups being naturally identified with \( P_n / \Gamma_2(P_n) \) and \( \Gamma_2(P_n) / \Gamma_3(P_n) \) respectively. We conclude that \( P_n / \Gamma_2(P_n) \) and \( \Gamma_2(P_n) / \Gamma_3(P_n) \) each admit a \( G \)-module structure inherited by the action of \( S_n \) on \( \mathcal{B} \) and \( \widetilde{\mathcal{B}}' \) respectively.

Given a group \( G \), let \( \mathbb{Z}[G] \) denote its group ring. The underlying Abelian group, also denoted by \( \mathbb{Z}[G] \), may be regarded as a \( \mathbb{Z}[G] \)-module (or as a \( G \)-module) via the multiplication in the ring \( \mathbb{Z}[G] \) (see [Br, Chapter I, Sections 2 and 3] for more details), namely:

\[
g \cdot \sum_{i=1}^{m} n_i g_i = \sum_{i=1}^{m} n_i (gg_i) \quad \text{for all} \quad m \in \mathbb{N}, g, g_1, \ldots, g_m \in G \quad \text{and} \quad n_1, \ldots, n_m \in \mathbb{Z}. \quad (6)
\]

The cohomology of the group \( G \) with coefficients in \( \mathbb{Z}[G] \) regarded as a \( G \)-module is well understood. In the case that \( G \) is finite, we have the following result concerning its embedding in certain extensions whose kernel is a free \( \mathbb{Z}[G] \)-module. First recall that if \( M \) is an Abelian group that fits into an extension of the following form:

\[
1 \longrightarrow M \longrightarrow E \longrightarrow G \longrightarrow 1, \quad (7)
\]

then \( M \) is also a \( \mathbb{Z}[G] \)-module, the action being given by (7).

**PROPOSITION 7.** Let \( G \) be a finite group. Given an extension of the form (7), suppose that \( M \) is a free \( \mathbb{Z}[G] \)-module. Then the short exact sequence (7) splits. In particular, \( G \) embeds in \( E \) as a subgroup, and the restriction of the projection \( E \longrightarrow G \) to the embedded copy of \( G \) is an isomorphism.

**Proof.** First suppose that \( M \cong \mathbb{Z}[G] \). By [Br, equation 6.5, p. 73], the group \( H^*(G, \mathbb{Z}[G]) \) is trivial for all \( * \geq 1 \). In particular, \( H^2(G, \mathbb{Z}[G]) = 0 \), which implies that any extension of the form (7) with \( M = \mathbb{Z}[G] \) is split [Br, Chapter IV, Theorem 3.12], where the action of the quotient on the kernel turns \( \mathbb{Z}[G] \) into a \( \mathbb{Z}[G] \)-module that is isomorphic to the one-dimensional free \( \mathbb{Z}[G] \)-module. Now suppose that \( M \) is an arbitrary free \( \mathbb{Z}[G] \)-module whose \( \mathbb{Z}[G] \)-module structure is defined by (7). So \( M = \bigoplus_J \mathbb{Z}[G] \) as a \( \mathbb{Z}[G] \)-module for some set \( J \), and \( H^2(G, M) \cong H^2(G, \bigoplus_J \mathbb{Z}[G]) \cong \bigoplus_J H^2(G, \mathbb{Z}[G]) = 0 \) by the first part of the proof. The short exact sequence (7) splits as in the case \( M \cong \mathbb{Z}[G] \). \( \square \)
3 Cayley-type results for subgroups of $B_n / \Gamma_k(P_n), k = 2, 3$

Let $k \in \{2, 3\}$. In this section, we prove Theorem 2 that may be viewed as an analogue of Cayley’s theorem for $B_n / \Gamma_k(P_n)$. The following proposition will be crucial in the proofs of Theorems 2 and 3.

**Proposition 8.** Let $k \in \{2, 3\}$, let $G$ be a finite group whose order is relatively prime with $k!$, let $m \geq 3$, and let $\varphi: G \to S_m$ be an embedding. Assume that for all $g \in G \setminus \{e\}$, the cycle decomposition of $\varphi(g)$ contains at most $k - 1$ fixed elements. Then the group $G$ embeds in $B_m / \Gamma_k(P_m)$.

**Proof.** Assume first that $k = 2$, so $|G|$ is odd. Let $\tilde{G}$ be the (isomorphic) image of $G$ by $\varphi$ in $S_m$. Taking the inverse image by $\varphi$ of $\tilde{G}$ in (2) with $n = m$ and $k = 2$ gives rise to the following short exact sequence:

$$1 \to P_m / \Gamma_2(P_m) \to \varphi^{-1}(\tilde{G}) \xrightarrow{\varphi^{-1}(\tilde{G})} \tilde{G} \to 1. \quad (8)$$

From Section 2, $G$, and hence $\tilde{G}$, acts on the free Abelian group $P_m / \Gamma_2(P_m)$ of rank $m(m - 1)/2$, and the restriction of this action to the basis $B$ is given by (5). Let $1 \leq i < j \leq m$, and let $g \in G$ be such that $\varphi(g) \cdot A_{i,j} = A_{i,j}$. Since $|G|$ is odd, the cycle decomposition of $\varphi(g)$ contains no transposition, and by Lemma 6(a) and the hypothesis on the fixed points of $\varphi(g)$, we see that $g = e$. So for all $1 \leq i < j \leq m$, the orbit of $A_{i,j}$ contains exactly $|G|$ elements. In particular, $|G|$ divides $m(m - 1)/2$, and $B$ may be decomposed as the disjoint union of the form $\prod_{k=1}^{m(m-1)/2|G|} O_k$, where each $O_k$ is an orbit of length $|G|$. For $k = 1, \ldots, m(m - 1)/2|G|$, let $e_k \in O_k$, and let $H_k$ denote the subgroup of $P_m / \Gamma_2(P_m)$ generated by $O_k$. Then $P_m / \Gamma_2(P_m) \cong \bigoplus_{k=1}^{m(m-1)/2|G|} H_k$, and for all $x \in O_k$, there exists a unique element $g \in G$ such that $\varphi(g) \cdot e_k = x$. Thus the map that to $x$ associates $g$ defines a bijection between $O_k$ and $G$. Since $O_k$ is a basis of $H_k$, if $h \in H_k$, there exists a unique family of integers $\{q_{gs}\}_{g \in G}$ such that $h = \prod_{g \in G} (\varphi(g) \cdot e_k)^{q_{gs}}$, and the map $\Phi: H_k \to \mathbb{Z}[G]$ defined by $\Phi(h) = \sum_{g \in G} q_{gs} g$ may be seen to be an isomorphism. Further, via $\Phi$, the action of $G$ on $H_k$ corresponds to the usual action of $G$ on $\mathbb{Z}[G]$. More precisely, if $\gamma \in G$, then:

$$\Phi(\varphi(\gamma) \cdot h) = \Phi\left(\varphi(\gamma) \cdot \prod_{g \in G} (\varphi(g) \cdot e_k)^{q_{gs}}\right) = \Phi\left(\prod_{g \in G} (\varphi(\gamma g) \cdot e_k)^{q_{gs}}\right) = \sum_{g \in G} q_{gs} \gamma g = \gamma \cdot \Phi(h),$$

the action of $\gamma$ on $\Phi(h)$ being given by (6). Hence $P_m / \Gamma_2(P_m) \cong \bigoplus_{k=1}^{m(m-1)/2|G|} \mathbb{Z}[G]$ as $\mathbb{Z}[G]$-modules, and by Proposition 7, we conclude that the extension (8) splits. Thus $G$ is isomorphic to a subgroup $\hat{G}$ of $\varphi^{-1}(\tilde{G})$, which in turn is a subgroup of $B_m / \Gamma_2(P_m)$, and this proves the result in the case $k = 2$. Now suppose that $k = 3$. Since $\gcd(|G|, 6) = 1$, $|G|$ is odd, and as above, $G$ is isomorphic to the subgroup $\hat{G}$ of $B_m / \Gamma_2(P_m)$. Consider the following extension:

$$1 \to \Gamma_2(P_m) / \Gamma_3(P_m) \to B_m / \Gamma_3(P_m) \xrightarrow{\varphi} B_m / \Gamma_2(P_m) \to 1,$$
where \( \rho : B_m/\Gamma_3(P_m) \to B_m/\Gamma_2(P_m) \) denotes the canonical projection. Taking the inverse image of \( \hat{G} \) by \( \rho \) gives rise to the following short exact sequence:

\[
1 \to \Gamma_2(P_m)/\Gamma_3(P_m) \to \rho^{-1}(\hat{G}) \rho^{-1}(\hat{G}) \to \hat{G} \to 1.
\]

(9)

Let \( \varphi' : \hat{G} \to S_m \) denote the embedding of \( \hat{G} \) in \( S_m \) given by composing \( \varphi \) by an isomorphism between \( \hat{G} \) and \( G \). Then \( \hat{G} \) acts on the kernel \( \Gamma_2(P_m)/\Gamma_3(P_m) \) of (9) via (5). Since \( \gcd(|\hat{G}|, 6) = 1 \), for all \( \hat{g} \in \hat{G} \setminus \{e\} \), the cycle decomposition of \( \varphi'(\hat{g}) \) contains neither a transposition nor a 3-cycle, and by hypothesis, \( \varphi'(\hat{g}) \) contains at most 2 fixed elements. It follows from Lemma 6(b) that if \( \varphi'(\hat{g}) : \alpha_{i,j,k} \in \{\alpha_{i,j,k}, \alpha_{i,j,k}^{-1}\} \), where \( 1 \leq i < j < k \leq n \) and \( \hat{g} \in \hat{G} \), then \( \hat{g} = e \). In particular, the orbits of \( \alpha_{i,j,k} \) and \( \alpha_{i,j,k}^{-1} \) are disjoint, every orbit contains exactly \( |G| \) elements, and thus \( |G| \) divides \( m(m-1)(m-2)/6 \). So there exists a basis of \( \Gamma_2(P_m)/\Gamma_3(P_m) \) that is the disjoint union of \( m(m-1)(m-2)/6|G| \) orbits of elements of \( \hat{B}' \), and that for all \( 1 \leq i < j < k \leq n \), contains exactly one element of \( \{\alpha_{i,j,k}, \alpha_{i,j,k}^{-1}\} \). As in the case \( k = 2 \), we conclude that the short exact sequence (9) splits, and that \( G \) embeds in \( B_m/\Gamma_3(P_m) \).

\[\square\]

**Remark 9.** An efficient way to use Proposition 8 is as follows. Let \( \varphi : G \to S_n \) be an embedding, and for an order-preserving inclusion \( i : \{1,2,\ldots,m\} \to \{1,2,\ldots,n\} \), where \( m < n \), consider the embedding \( S_m \to S_n \). Suppose that the homomorphism \( \varphi \) factors through \( S_m \), and let \( \varphi' : G \to S_m \) be the factorisation. It may happen that the hypotheses of Proposition 8 hold for \( \varphi' \) but not for \( \varphi \). In this case, we may apply this proposition to \( \varphi' \) to conclude the existence of an embedding of \( G \) in \( B_m/\Gamma_k(P_m) \), which in turn implies that \( G \) embeds in \( B_n/\Gamma_k(P_n) \).

We are now able to prove Theorem 2.

**Proof of Theorem 2.** Let \( G \) be a finite group, and let \( k \in \{2,3\} \). If \( G \) embeds in \( B_{|G|}/\Gamma_k(P_{|G|}) \) then Theorem 1 implies that \( \gcd(|G|, k!) = 1 \). Conversely, suppose that \( \gcd(|G|, k!) = 1 \). Consider the classical embedding of \( G \) in \( S_{|G|} \) that is used in the proof of Cayley’s theorem (note that we identify \( S_G \) with \( S_{|G|} \)). More precisely, let \( \psi : G \times G \to G \) denote the action of \( G \) on itself given by left multiplication. For all \( g \in G \), the map \( \psi_g : G \to G \) defined by \( \psi_g(h) = \psi(g,h) = gh \) is a permutation of \( G \), and the map \( \Psi : G \to S_{|G|} \) defined by \( \Psi(g) = \psi_g \) is an injective homomorphism, so \( \hat{G} = \{\psi_g \mid g \in G\} \) is a subgroup of \( S_{|G|} \) that is isomorphic to \( G \). The action \( \psi \) is free: if \( h \in G \) then \( h = \psi_g(h) \) if and only if \( g = e \). In particular, if \( g \neq e \) then \( \psi_g \) is fixed-point free, and so the permutation \( \Psi(g) \) is fixed-point free for all \( g \in G \setminus \{e\} \). Taking \( m = |G| \), the hypotheses of Proposition 8 are satisfied for the embedding \( \Psi : G \to S_{|G|} \), and we conclude that \( G \) embeds in \( B_{|G|}/\Gamma_k(P_{|G|}) \).

\[\square\]

## 4 Embeddings of some semi-direct products in \( B_n/\Gamma_k(P_n) \), \( k \in \{2,3\} \)

Let \( m, n \in \mathbb{N} \) and let \( k \in \{2,3\} \). In this section, we study the problem of embedding groups of the form \( \mathbb{Z}_n \rtimes \mathbb{Z}_m \) in \( B_n/\Gamma_k(P_n) \), where the representation \( \theta : \mathbb{Z}_m \to \text{Aut}(\mathbb{Z}_n) \)

8
is taken to be injective. With additional conditions on \( \theta \), in Section 4.1, we prove Theorem 3. In Section 4.2, we study the two non-Abelian groups of order 27. The first such group is of the form \( \mathbb{Z}_n \times_{\theta} \mathbb{Z}_m \), where \( \theta \) is injective, but the additional conditions of Theorem 3 are not satisfied. The second such group is not of the form \( \mathbb{Z}_n \times_{\theta} \mathbb{Z}_m \). We prove that both of these groups embed in \( B_9/\Gamma_2(P_9) \). In the case of the first group, this shows that the hypotheses of Theorem 3 are sufficient to embed \( \mathbb{Z}_n \times_{\theta} \mathbb{Z}_m \) in \( B_n/\Gamma_k(P_n) \), but not necessary. With respect to (3), these groups also satisfy \( m(G) = \ell_k(G) < |G| \), which is coherent with [BM, Corollary 13] in the case \( k = 2 \).

### 4.1 Proof of Theorem 3

Let \( m, n \in \mathbb{N} \). In this section, \( G \) will be a group of the form \( \mathbb{Z}_n \times_{\theta} \mathbb{Z}_m \). We study the question of whether \( G \) embeds in \( B_n/\Gamma_k(P_n) \), where \( k \in \{2, 3\} \). By Theorem 1, when \( G = \mathbb{Z}_n \times_{\theta} \mathbb{Z}_m \) for such an embedding to exist, \( \gcd(|G|, k!) = 1 \), and so we shall assume from now on that this is the case. In order to apply Proposition 8, we will make use of a specific embedding of \( G \) in \( S_n \) studied by Marin in the case where \( n \) is prime and \( m = (n - 1)/2 \) [M2], as well as the restriction to \( G \) of the action of \( S_n \) on \( P_9/\Gamma_2(P_9) \) and \( \Gamma_2(P_9)/\Gamma_3(P_9) \) described by equation (5). If \( q \in \mathbb{N} \), we will denote the image of an integer \( r \) under the canonical projection \( \mathbb{Z} \rightarrow \mathbb{Z}_q \) by \( r_q \), or simply by \( r \) if no confusion is possible.

Following [M2, proof of Corollary 3.11], we start by describing a homomorphism from \( K \) to \( S_A \), for groups of the form \( K = A \times_{\theta} H \), where \( A \) and \( H \) are finite, \( A \) is Abelian, and \( S_A \) denotes the symmetric group on the set \( A \). Let \( (u, v) \in K \), where the elements of \( K \) are written with respect to the semi-direct product \( A \times_{\theta} H \), and let \( \varphi_{(u, v)} : A \rightarrow A \) be the affine transformation defined by:

\[
\varphi_{(u, v)}(z) = \theta(v)(z) + u \quad \text{for all } z \in A.
\]

**Lemma 10.**

(a) For all \( (u, v) \in K \), the map \( \varphi_{(u, v)} : A \rightarrow A \) defined in (10) is a bijection.

(b) Let \( \varphi : K \rightarrow S_A \) be the map defined by \( \varphi(u, v) = \varphi_{(u, v)} \) for all \( (u, v) \in K \). Then \( \varphi \) is a homomorphism. If the action \( \theta : H \rightarrow \text{Aut}(A) \) is injective then \( \varphi \) is too.

**Proof.**

(a) If \( (u, v) \in K \), the statement follows from the fact that \( \theta(v) \) is an automorphism of \( A \).

(b) Part (a) implies that the map \( \varphi \) is well defined. We now prove that \( \varphi \) is a homomorphism. If \( (u_1, v_1), (u_2, v_2) \in K \), then for all \( z \in A \), we have:

\[
(\varphi_{(u_2, v_2)} \circ \varphi_{(u_1, v_1)})(z) = \theta(v_2)(\theta(v_1)(z) + u_1) + u_2 = \theta(v_2)(\theta(v_1)(z)) + \theta(v_2)(u_1) + u_2 = \theta(v_2v_1)(z) + \theta(v_2)(u_1) + u_2 = \varphi_{(u_2 + \theta(v_2)(u_1), v_2v_1)}(z) = \varphi_{(u_2, v_2)(u_1, v_1)}(z),
\]

so \( \varphi_{(u_2, v_2)} \circ \varphi_{(u_1, v_1)} = \varphi_{(u_2, v_2)(u_1, v_1)} \), and \( \varphi \) is a homomorphism. Finally, suppose that \( \theta \) is injective, and let \( (u, v) \in \text{Ker}(\varphi) \). Then \( z = \varphi(u, v)(z) = \varphi_{(u, v)}(z) = \theta(v)(z) + u \) for all \( z \in A \). Taking \( z \) to be the trivial element \( e_A \) of \( A \) yields \( u = e_A \). Hence \( \theta(v) = \text{Id}_A \), and it follows that \( v \) is the trivial element \( H \) by the injectivity of \( \theta \), which completes the proof of the lemma. \( \square \)
As above, we consider the group \( G = \mathbb{Z}_n \rtimes \theta \mathbb{Z}_m \), where \( \theta : \mathbb{Z}_m \rightarrow \text{Aut}(\mathbb{Z}_n) \) is the associated action. Note that we can apply the construction of equation (10) to \( G \), and so the conclusions of Lemma 10 hold for \( G \). The element \( 1_m \) generates the additive group \( \mathbb{Z}_m \), so \( \theta(1_m) \) is an automorphism of \( \mathbb{Z}_n \) whose order divides \( m \), and since any automorphism of \( \mathbb{Z}_n \) is multiplication by an integer that is relatively prime with \( n \), there exists \( 1 \leq t < n \) such that \( \text{gcd}(t, n) = 1 \), \( \theta(1_m) \) is multiplication by \( t \), and \( t^m \equiv 1 \mod n \). If \( \theta \) is injective, the order of the automorphism \( \theta(1_m) \) is equal to \( m \), and so \( t^l \neq 1 \mod n \) for all \( 1 \leq l < m \), but this does not imply that \( t^l - 1 \) is relatively prime with \( n \). However, the condition that \( \text{gcd}(t^l - 1, n) = 1 \) for all \( 1 \leq l < m \) is the hypothesis that we require in order to prove Theorem 3, and as we shall now see, implies that \( \theta \) is injective.

**Lemma 11.** Let \( n, m \in \mathbb{N} \), let \( G \) be a semi-direct product of the form \( \mathbb{Z}_n \rtimes \theta \mathbb{Z}_m \), and let \( 1 \leq t < n \) be such that \( \theta(1_m) \) is multiplication in \( \mathbb{Z}_n \) by \( t \). Suppose that \( \text{gcd}(t^l - 1, n) = 1 \) for all \( 1 \leq l < m - 1 \).

(a) The action \( \theta : \mathbb{Z}_m \rightarrow \text{Aut}(\mathbb{Z}_n) \) is injective, and the homomorphism \( \varphi : G \rightarrow S_{\mathbb{Z}_n} \) defined in Lemma 10 is injective.

(b) For all \( (u, v) \in G \setminus \{(0_n, 0_m)\} \), the permutation \( \varphi(u, v) \) fixes at most one element, and if \( v \neq 0_m \), then \( \varphi(u, v) \) fixes precisely one element.

**Proof.**

(a) To prove the first part, we argue by contraposition. Suppose that \( \theta \) is not injective. Then there exists \( 1 \leq l < m \) such that \( \theta(l_m) = \text{Id}_{\mathbb{Z}_n} \). Now \( \theta(1_m) \) is multiplication by \( t \), so \( \theta(l_m) \) is multiplication by \( t^l \), and thus \( t^l \equiv 1 \mod n \), which implies that \( \text{gcd}(t^l - 1, n) \neq 1 \). The second part of the statement follows from Lemma 10(b).

(b) Let \( (u, v) \in G \setminus \{(0_n, 0_m)\} \). If \( v = 0_m \) then \( u \neq 0_n \), so \( \varphi_{(u,0_m)}(z) = z + u \neq z \) for all \( z \in \mathbb{Z}_n \), hence \( \varphi_{(u,0_m)} \) is fixed-point free. So suppose that \( v \neq 0_m \). Since \( \theta(v) \) is multiplication by \( t^v \), the corresponding affine transformation \( \varphi_{(u,v)} : \mathbb{Z}_n \rightarrow \mathbb{Z}_n \) is given by \( \varphi_{(u,v)}(z) = t^v z + u \) for all \( z \in \mathbb{Z}_n \). By hypothesis, \( \text{gcd}(t^v - 1, n) = 1 \), so \( t^v - 1 \) is invertible in \( \mathbb{Z}_n \), and if \( z \in \mathbb{Z}_n \), we have:

\[
\varphi_{(u,v)}(z) = z \iff t^v z + u = z \iff (t^v - 1)z = -u \iff z = -u(t^v - 1)^{-1}
\]

in \( \mathbb{Z}_n \). Hence \( \varphi_{(u,v)} \) possesses a unique fixed point. \( \square \)

The above framework enables us to prove Theorem 3 using Proposition 8.

**Proof of Theorem 3.** Let \( \varphi : G \rightarrow S_{\mathbb{Z}_n} \) be the embedding of \( G \) in \( S_{\mathbb{Z}_n} \) of Lemma 10(b). By Lemma 11(b), for all \( g \in G \setminus \{e\} \), the cycle decomposition of the permutation \( \varphi(g) \) contains at most one fixed point. So the embedding \( \varphi \) satisfies the hypotheses of Proposition 8, from which we conclude that \( G \) embeds in \( B_n / \Gamma_2(P_n) \) (resp. in \( B_n / \Gamma_3(P_n) \)) if \( mn \) is odd (resp. if \( \text{gcd}(mn, 6) = 1 \)). \( \square \)

As an application of Theorem 3, we consider groups of the form \( \mathbb{Z}_n \rtimes \theta H \), where \( H \) is finite, \( n = p^r \) is a power of an odd prime \( p \), where \( r \in \mathbb{N} \), and the homomorphism \( \theta : H \rightarrow \text{Aut}(\mathbb{Z}_{p^r}) \) is injective. Recall from \( [\mathbb{Z}, \text{p. 146}, \text{lines 16–17}] \) that:

\[
\text{Aut}(\mathbb{Z}_{p^r}) \cong \mathbb{Z}_{(p-1)p^{r-1}} \cong \mathbb{Z}_{p-1} \oplus \mathbb{Z}_{p^{r-1}},
\]

where the isomorphisms of (11) are described in \( [\mathbb{Z}, \text{pp. 145–146}] \). We now prove Corollary 4 by studying injective actions \( \theta : H \rightarrow \mathbb{Z}_{(p-1)p^{r-1}} \), where \( H \) is a cyclic group whose order is an odd divisor of \( p - 1 \).
Proof of Corollary 4. Let \( p > 2 \) be prime, let \( p - 1 = 2^l d \), where \( d \) is odd, and let \( d_1 \) be a divisor of \( d \). So identifying \( \text{Aut}(Z_p^r) \) with \( Z_{p-1} \oplus Z_{p-1} \) via (11), and taking the subgroup \( H \) in the above discussion to be \( Z_{d_1} \), there exists an injective homomorphism \( \theta: Z_{d_1} \rightarrow Z_{p-1} \oplus Z_{p-1} \), where \( \theta(1_{d_1}) \) is an automorphism of \( Z_{p} \) given by multiplication by an integer \( t \) that is relatively prime with \( p \), and the order \( d_1 \) of this automorphism is also relatively prime with \( p \). In particular, the order of \( d_1 \) is odd to \( 1 \). We claim that gcd\((t^l - 1, p) = 1 \) for all \( 0 < l < d_1 \). Suppose on the contrary that \( t^l - 1 \) is divisible by \( p \) for some \( 0 < l < d_1 \). Then \( t^l = 1 + kp \), where \( k \in \mathbb{N} \), and \( \tau \) is of order \( 1 \) in \( Z_{p}^* \), which contradicts the fact that \( t \) is of order \( d_1 \) and gcd\((d_1, p) = 1 \). This proves the claim. Part (a) (resp. part (b)) follows using the fact that the order of \( Z_{p}^* \) is odd (resp. relatively prime with 6) and by applying Theorem 3.

Remark 12. As we mentioned in the introduction, the results of Corollary 4 are sharp in the sense that if \( k \in \{2, 3\} \), the groups \( Z_{p}^* \) satisfy \( \ell_k(G) = m(G) = p^r \) if \( d > 1 \), where \( k \in \{2, 3\} \). This result no longer holds if we remove the hypothesis that the order of the group being acted upon is a prime power. For example, if in the semi-direct product \( G = Z_{n} \ltimes Z_d \), we take \( n = 15 \) and \( d = 1 \) then \( G \cong Z_3 \times Z_5 \), and \( \ell_2(G) = m(G) = 8 < 15 \) using [GGO1, Theorem 3(b)] or [BM, Corollary 13].

4.2 Further examples

In this final section, we give examples of two semi-direct products of the form \( Z_\theta \ltimes \theta Z_3 \) and \( (Z_3 \oplus Z_3) \ltimes \theta Z_3 \) respectively that do not satisfy the hypotheses of Theorem 3, but that embed in \( B_9 / \Gamma_2(P_9) \). We start with some general comments. If \( p \) is an odd prime, consider the group \( G = Z_{p}^r \ltimes \theta Z_{p-1}(p-1) \), where with respect to the notation of [Z, p. 146, line 8], the homomorphism \( \theta: Z_{p-1}(p-1) \rightarrow \text{Aut}(Z_{p}^r) \) sends \( 1_{p-1}(p-1) \) to the element of \( \text{Aut}(Z_{p}^r) \) given by multiplication in \( Z_{p}^r \) by \( t' \), where \( t' = (1 + p)g_1 \), and where the order of \( g_1 \) (resp. \( 1 + p \)) is equal to \( p - 1 \) (resp. \( p^r-1 \)) in the multiplicative group \( Z_{p}^r \). If \( d_1 \) is an odd divisor of \( p^r-1(p-1) \), let \( q = p^r-1(p-1)/d_1 \), and consider the subgroup \( Z_{p}^r \ltimes \theta q' \) \( Z_{d_1} \) of \( G \), where \( Z_{d_1} \) is the subgroup of \( Z_{p}^r \ltimes \theta q \) of order \( d_1 \), and \( \theta': Z_{d_1} \rightarrow \text{Aut}(Z_{p}^r) \) is the restriction of \( \theta \) to \( Z_{d_1} \). Then \( \theta'(1_{d_1}) = \theta(q_{p^r-1}(p-1)) \) is multiplication by \( t = t^q \) in \( Z_{p}^r \), and by injectivity, \( t \) is of order \( d_1 \) in \( Z_{p}^r \). If further \( d_1 \) is divisible by \( p \) then \( t^{d_1/p} \) is of order \( p \) in \( Z_{p}^r \), and by [Z, p. 146, line 12], \( t^{d_1/p} \equiv (1 + p)^{\lambda(p-2)} \mod p^r \), where \( \lambda \in \mathbb{N} \) and gcd\((\lambda, p) = 1 \). It follows that \( t^{d_1/p} - 1 \) is divisible by \( p \), and since \( 0 < d_1/p < d_1 \), the hypotheses of Theorem 3 are not satisfied for the group \( Z_{p}^r \ltimes \theta \) \( Z_{d_1} \). As Example 13(a) below shows, if \( p = 3 \) and \( r = 2 \), such a group may nevertheless embed in \( B_{p}^r / \Gamma_2(P_{p}^r) \). In Example 13(b), we show that the other non-Abelian group of order 27, which is of the form \( (Z_3 \oplus Z_3) \ltimes Z_{p}^r \), also embeds in \( B_{p} / \Gamma_2(P_{p}^r) \). It does not satisfy the hypotheses of Theorem 3 either.

Examples 13. Suppose that \( G \) is a group of order 27 that embeds in \( S_9 \). If \( k = 2 \) and \( n = 9 \) in (2), taking the preimage of \( G \) by \( \sigma \) leads to the following short exact sequence:

\[
1 \rightarrow P_9 / \Gamma_2(P_9) \rightarrow \sigma^{-1}(G) \rightarrow G \rightarrow 1,
\] (12)
where the rank of the free Abelian group $P_9 / \Gamma_2 (P_9)$ is equal to 36. As we shall now see, if $G$ is one of the two non-Abelian groups of order 27, the action of $S_9$ on the basis $B$ of $P_9 / \Gamma_2 (P_9)$ given by (5) restricts to an action of $G$ on $B$ for which there are two orbits, that of $A_{1,2}$, which contains 9 elements, and is given by:

$$\mathcal{O} = \{ A_{1,2}, A_{8,9}, A_{5,6}, A_{2,3}, A_{7,8}, A_{4,5}, A_{1,3}, A_{7,9}, A_{4,6} \},$$

(13)

and that of $A_{5,9}$, which contains the remaining 27 elements of $B$. Let $H$ be the subgroup of $P_9 / \Gamma_2 (P_9)$ generated by the orbit of $A_{5,9}$. Then $H \cong \mathbb{Z}^27$, and $H$ is not normal in $B_9 / \Gamma_2 (P_9)$, but it is normal in the subgroup $\bar{\sigma}^{-1} (G)$ of $B_9 / \Gamma_2 (P_9)$ since the basis $B \setminus \mathcal{O}$ of $H$ is invariant under the action of $G$. We thus have an extension:

$$1 \longrightarrow H \longrightarrow \bar{\sigma}^{-1} (G) \xrightarrow{\pi} \tilde{H} \longrightarrow 1,$$

(14)

where $\tilde{H} = \bar{\sigma}^{-1} (G) / H$, and $\pi : \bar{\sigma}^{-1} (G) \longrightarrow \tilde{H}$ is the canonical projection. Equation (12) induces the following short exact sequence:

$$1 \longrightarrow (P_9 / \Gamma_2 (P_9)) / H \longrightarrow \tilde{H} \xrightarrow{\bar{\sigma}} G \longrightarrow 1,$$

(15)

where $\bar{\sigma} : \tilde{H} \longrightarrow G$ is the surjective homomorphism induced by $\bar{\sigma}$, and we also have an extension:

$$1 \longrightarrow H \longrightarrow P_9 / \Gamma_2 (P_9) \xrightarrow{\rho} (P_9 / \Gamma_2 (P_9)) / H \longrightarrow 1,$$

(16)

obtained from the canonical projection $\rho : P_9 / \Gamma_2 (P_9) \longrightarrow (P_9 / \Gamma_2 (P_9)) / H$. From the construction of $H$, and using the fact that $P_9 / \Gamma_2 (P_9)$ (resp. $H$) is the free Abelian group of rank 36 (resp. 27) for which $B$ (resp. $B \setminus \mathcal{O}$) is a basis, the kernel of (15) is isomorphic to $\mathbb{Z}^9$ and a basis is given by the $H$-cosets of the nine elements of $\mathcal{O}$. Further, the restriction of $\rho$ to the subgroup of $P_9 / \Gamma_2 (P_9)$ generated by $\mathcal{O}$ is an isomorphism, and thus the set $\rho (\mathcal{O})$ is a basis of $(P_9 / \Gamma_2 (P_9)) / H$, which we denote by $\mathcal{O}'$. In the examples below, we shall construct an explicit embedding $\iota : G \longrightarrow \tilde{H}$ of $G$ in $\tilde{H}$. This being the case, using (14), we thus obtain the following short exact sequence:

$$1 \longrightarrow H \longrightarrow \pi^{-1} (\iota (G)) \xrightarrow{\pi |_{\pi^{-1} (\iota (G))}} \iota (G) \longrightarrow 1.$$

(17)

Now $H$ is isomorphic to $\mathbb{Z} [G]$, and the action of $\iota (G)$ on $H$ is given via (5). It follows from Proposition 7 that (17) splits. Hence $G$ embeds in $\pi^{-1} (\iota (G))$, which is a subgroup of $\bar{\sigma}^{-1} (G)$, and so it embeds in $B_9 / \Gamma_2 (P_9)$. We could have attempted to embed $G$ in $B_9 / \Gamma_2 (P_9)$ directly via (12). However one of the difficulties with this approach is that the rank of the kernel is 36, whereas that of the kernel of (15) is much smaller, and this decreases greatly the number of calculations needed to show that $G$ embeds in $\tilde{H}$. We now give the details of the computations of this embedding in the two cases.

(a) Consider the semi-direct product $Z_9 \rtimes_{\theta'} Z_3$, where $\theta' : Z_3 \longrightarrow \text{Aut} (Z_9)$ is as defined in the second paragraph of this subsection. We have $g_1 = 8$, so $\theta' (13)$ is multiplication by $(1 + 3)$. (8) $= 32 \equiv 5 \text{ mod } 9$. It will be more convenient for us to work with a different automorphism, but that gives rise to a semi-direct product that is isomorphic to $Z_9 \rtimes_{\theta'} Z_3$ as follows. Let $\varphi : Z_9 \longrightarrow Z_9$ be the automorphism given by multiplication by 4, let $\theta : Z_3 \longrightarrow \text{Aut} (Z_9)$ be such that $\theta (13) = \varphi$, and let $G = Z_9 \rtimes_{\theta} Z_3$. Then $\theta' (13) = \varphi \circ \theta (13)$, which implies that the groups $G$ and $Z_9 \rtimes_{\theta'} Z_3$ are isomorphic,
see [AB, Chap. 1.2, Proposition 12]. It is clear that \( \theta \) is injective, but that the hypothesis of Theorem 3 that \( \gcd(t^l - 1, n) = 1 \) for all \( 1 \leq l < d \) is not satisfied if \( l = 1 \). Nevertheless, the group \( G \) embeds in \( B_9/\Gamma_2(P_9) \). To see this, consider the elements \( \alpha = (1, 2, 3)(4, 5, 6)(7)(8)(9) \) and \( \beta = (1, 4, 7, 3, 5, 8, 2, 6, 9) \) of \( S_9 \). Then:

\[
\alpha \beta \alpha^{-1} = (1, 2, 3)(4, 5, 6)(7)(8)(9). (1, 4, 7, 3, 5, 8, 2, 6, 9). ((1, 2, 3)(4, 5, 6)(7)(8)(9))^{-1} = (1, 5, 9, 3, 6, 7, 2, 4, 8) = (1, 4, 7, 3, 5, 8, 2, 6, 9)^4 = \beta^4,
\]

and an embedding of \( G \) in \( S_9 \) is realised by sending \( 13 \) (resp. \( 19 \)) to \( \alpha \) (resp. \( \beta \)). From now on, we identify \( G \) with its image in \( S_9 \) under this embedding. One may check that \( \mathcal{O} \) and \( B \setminus \mathcal{O} \) are the two orbits arising from the action of \( G \) on \( B \) given by (5) (for future reference, note that the order of the elements of \( \mathcal{O} \) is that obtained by the action of successive powers of \( \beta \)). We define the map \( i: G \to \hat{H} \) on the generators of \( G \) by \( i(\alpha) = \hat{\alpha} \) and \( i(\beta) = \hat{\beta} \), where \( \hat{\alpha} = \sigma_2σ_1^{-1}σ_5σ_4^{-1} \) and \( \hat{\beta} = A_{1, 2}A_{8, 9}^{-1}wσ_7σ_6σ_5σ_4^{-1}σ_3σ_2^{-1}σ_1^{-1}w^{-1} \), and where \( w = σ_3σ_2σ_3σ_4σ_5σ_3σ_6 \). By abuse of notation, we will denote an element of \( B_9/\Gamma_2(P_9) \) in the same way as its projection on the quotient \( (B_9/\Gamma_2(P_9))/H \). We claim that \( \hat{\alpha}\hat{\beta}\hat{\alpha}^{-1}\hat{\beta}^{-4} = 1 \) in \( \hat{H} \), from which we may conclude that \( i \) extends to a group homomorphism. To prove the claim, using [GGO1, Proposition 12] and the action of \( \beta \) on the orbit of \( A_{1, 2} \) mentioned above, first note that:

\[
\hat{\alpha}\hat{\beta}\hat{\alpha}^{-1}\hat{\beta}^{-4} = \hat{\alpha}A_{1, 2}A_{8, 9}^{-1}b\hat{\alpha}^{-1}(A_{1, 2}A_{8, 9}^{-1}b)^{-4} = A_{1, 3}A_{8, 9}^{-1}\hat{\alpha}b\hat{\alpha}^{-1}b^{-4}. A_{2, 3}^{-1}A_{7, 8}. A_{5, 6}^{-1}A_{2, 3}. A_{8, 9}^{-1}A_{5, 6}. A_{1, 2}^{-1}A_{8, 9} \]

\[
= A_{1, 2}^{-1}A_{7, 8}A_{1, 3}A_{8, 9}^{-1}\hat{\alpha}b\hat{\alpha}^{-1}b^{-4}.
\]

To obtain the final equality, we have also used the fact that \( \hat{\alpha}\hat{\beta}\hat{\alpha}^{-1}b^{-4} \) belongs to the quotient \( (P_9/\Gamma_2(P_9))/H \), so commutes with the other terms in the expression. To compute \( \hat{\alpha}\hat{\beta}\hat{\alpha}^{-1}b^{-4} \) in terms of the basis \( \mathcal{O}' \) of \( (P_9/\Gamma_2(P_9))/H \), we use the method of crossing numbers given in [GGO1, Proposition 15], except that since we are working in \( (P_9/\Gamma_2(P_9))/H \), using the isomorphism \( \rho \big|_{\langle \mathcal{O} \rangle} : \langle \mathcal{O} \rangle \to (P_9/\Gamma_2(P_9))/H \) induced by (16), it suffices to compute the crossing numbers of the pairs of strings corresponding to the elements of \( \mathcal{O} \) given in (13). Using the braid \( \hat{\alpha}\hat{\beta}\hat{\alpha}^{-1}b^{-4} \) illustrated in Figure 1, one may verify that:

\[
\hat{\alpha}\hat{\beta}\hat{\alpha}^{-1}b^{-4} = A_{1, 2}A_{1, 3}^{-1}A_{7, 8}^{-1}A_{8, 9}
\]

in the quotient \( (P_9/\Gamma_2(P_9))/H \). It follows from equations (18) and (19) that \( \hat{\alpha}\hat{\beta}\hat{\alpha}^{-1}\hat{\beta}^{-4} = 1 \) in \( \hat{H} \), which proves the claim. Thus \( \langle \hat{\alpha}, \hat{\beta} \rangle \) is a quotient of \( G \), but since it is non Abelian, and the only non-Abelian quotient of \( G \) is itself, we conclude that \( \langle \hat{\alpha}, \hat{\beta} \rangle \cong G \), and hence \( i \) is an embedding. It follows from the discussion at the beginning of these examples that \( G \) embeds in \( \pi^{-1}(\iota(G)) \), and therefore in \( B_9/\Gamma_2(P_9) \).

(b) We now give an explicit example of a non-Abelian group \( G \) of the form \( A \rtimes \mathbb{Z}_m \) that embeds in \( B_{|A|}/\Gamma_2(P_{|A|}) \), where \( A \) is a non-cyclic finite Abelian group. To our knowledge, this is the first explicit example of a finite group that embeds in such a quotient but that is not a semi-direct product of two cyclic groups. In particular, this subgroup does not satisfy the hypothesis of Theorem 3 either. Let \( G \) be the Heisenberg
Figure 1: The braid $\hat{\alpha} b \hat{\alpha}^{-1} b^{-4}$

Figure 2: The braids $[\hat{\alpha}, \hat{\beta}], \hat{\gamma}^{-1}$ and $[\hat{\alpha}, \hat{\gamma}]$
group mod $p$ of order $p^3$, where $p$ is an odd prime. There exists an extension of the form:

$$1 \to \mathbb{Z}_p \to G \to \mathbb{Z}_p \oplus \mathbb{Z}_p \to 1, \tag{20}$$

and a presentation of $G$ is given by:

$$\langle a, b, c \mid a^p = b^p = c^p = 1, c = [a, b] \text{ and } [a, c] = [b, c] = 1 \rangle, \tag{21}$$

where $c$ is an element of $G$ emanating from a generator of the kernel $\mathbb{Z}_p$ of the extension (20), and $a$ and $b$ are elements of $G$ that project to the generators of the summands of the quotient. This group is also isomorphic to $(\mathbb{Z}_p \oplus \mathbb{Z}_p) \times_\theta \mathbb{Z}_p$, where the action\footnote{\cite{GGO1}, equations (14) and (16)} $	heta: \mathbb{Z}_p \to \text{Aut}(\mathbb{Z}_p \oplus \mathbb{Z}_p)$ is given by $\theta(1_p) = \left( \begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix} \right)$. From now on, we assume that $p = 3$. Consider the map from $G$ to $S_9$ given by sending $a$ to $\alpha = (1, 4, 7)(2, 5, 8)(3, 6, 9)$ and $b$ to $\beta = (1)(2)(3)(4, 5, 6)(7, 9, 8)$, so $c$ is sent to $\gamma = [\alpha, \beta] = (1, 2, 3)(4, 5, 6)(7, 9, 8)$. The relations of (21) hold for the elements $a, \beta$ and $\gamma$, and since the only non-Abelian quotient of $G$ is $G$ itself, it follows that this map extends to an embedding of $G$ in $S_9$. Once more, one may check that $O$ and $B \setminus O$ are the orbits arising from the action of $G$ on $B$. It remains to show that $G$ embeds in $\bar{H}$. Let $\iota: G \to \bar{H}$ be the map defined by $\iota(a) = \hat{a}, \iota(\beta) = \hat{\beta}$ and $\iota(\gamma) = \hat{\gamma}$, where:

$$\hat{a} = w\sigma_1\sigma_4^{-1}\sigma_5\sigma_7^{-1}w'^{-1}, \hat{\beta} = \sigma_5\sigma_4^{-1}\sigma_7\sigma_8^{-1} \text{ and } \hat{\gamma} = \sigma_2\sigma_1^{-1}\sigma_5\sigma_4^{-1}\sigma_7\sigma_8^{-1},$$

and where $w' = \sigma_3\sigma_2\sigma_4\sigma_6\sigma_5\sigma_4\sigma_7\sigma_6$. Using the notation of \cite[equations (14) and (16)]{GGO1}, $\hat{a} = w\delta_0\delta_3\delta_6\delta_3\delta_6\delta_3w'^{-1} = w\delta(0, 3, 3, 3)w'^{-1}, \hat{\beta} = \delta_3\delta_6\delta_3^{-1}$ and $\hat{\gamma} = w\hat{\alpha}w'^{-1}$. So these three elements are of order 3 in $B_9/\Gamma_2(P_9)$ by the argument of \cite[line 4, p. 412]{GGO1}, and hence they satisfy the first three relations of (21) in $\bar{H}$, $a, b$ and $c$ being taken to be $\hat{a}, \hat{\beta}$ and $\hat{\gamma}$ respectively. One may check in a straightforward manner that $[\hat{\beta}, \hat{\gamma}] = 1$ as elements of $B_9$, hence $[\hat{\beta}, \hat{\gamma}] = 1$ in $\bar{H}$. To see that the two remaining relations of (21) hold, as in the first example, we use the method of crossing numbers of the strings given in \cite[Proposition 15]{GGO1}, but in $\bar{H}$ rather than $P_9/\Gamma_2(P_9)$. In this way, we see from Figures (2)(a) and (b) that $[\hat{a}, \hat{\beta}], \hat{\gamma}^{-1} = 1$ and $[\hat{a}, \hat{\gamma}] = 1$ in $\bar{H}$. It thus follows that $\langle \hat{a}, \hat{\beta}, \hat{\gamma} \rangle$ is a quotient of $G$, but since this subgroup is non-Abelian, and the only non-Abelian quotient of $G$ is itself, we conclude that $\langle \hat{a}, \hat{\beta} \rangle \cong G$, and hence $\iota$ is an embedding. Once more, it follows from the discussion at the beginning of these examples that $G$ embeds in $\pi^{-1}(\iota(G))$, and therefore in $B_9/\Gamma_2(P_9)$.

**Remarks 14.**

(a) Let $G$ be one of the two groups of order 27 analysed in Examples 13. With the notation introduced at the beginning of Section 4, the fact that $G$ embeds in $B_9/\Gamma_2(P_9)$ implies that $\ell_2(G) \leq 9$. On the other hand, if $G$ embeds in $S_r$ then $r \geq 9$ by Lagrange’s Theorem. Hence $m(G) \geq 9$, and it follows from (3) that $m(G) = \ell_2(G) = 9$, which is coherent with \cite[Corollary 13]{BM} in the case $k = 2$.

(b) The finite groups of the form $A \rtimes_\theta H$, where $A$ is a finite Abelian group, $H$ is an arbitrary finite group, and $\theta: H \to \text{Aut}(A)$ is injective, embed in $S_A$ by Lemma 10. From \cite[Corollary 13]{BM}, if the order of $A \rtimes_\theta H$ is odd then it embeds in $B_{|A|}/\Gamma_2(P_{|A|})$. We would like to be able to determine which of these groups embed in $B_{|A|}/\Gamma_3(P_{|A|})$.
