Abstract

We consider extremal correlation functions, involving arbitrary number of BPS (chiral or twisted chiral) operators and exactly one anti-BPS operator in 2D $\mathcal{N} = (2,2)$ theories. These correlators define the structure constants in the rings generated by the BPS operators with their operator product expansions. We present a way of computing these correlators from the sphere partition function of a deformed theory using localization. Relating flat space and sphere correlators is nontrivial due to operator mixing on the sphere induced by conformal anomaly. We discuss the supergravitational source of this complication and a resolution thereof. Finally, we demonstrate the process for the Quintic GLSM and the Landau-Ginzburg minimal models.

Chiral and twisted chiral rings, collectively referred to as the BPS rings in what follows, are algebraic structures that can be assigned to $\mathcal{N} = (2, 2)$ supersymmetric quantum field theories (QFTs) in two dimensions. On a general ground such assignments let us distinguish between different theories and identify various types of equivalence classes of QFTs and dualities. More specifically, the BPS rings are renormalization group (RG) invariants that can be used to distinguish between different universality classes of 2D $\mathcal{N} = (2, 2)$ theories. These rings are interesting objects from a mathematical point of view as well, as chiral and the twisted chiral rings of a given theory belong to two different topological sectors of the theory and their structures encode complex structure invariants and Kähler structure invariants of some geometric spaces associated to the theory [1, 2, 3].

Analogous to the 2D case, chiral rings can be defined for 4D $\mathcal{N} = 2$ superconformal theories as well and recently a method has been used to compute the ring structure of these 4D chiral rings [4], which entails computing the so called extremal correlation functions, using the exactly known sphere partition function of the theory [5]. In this paper we use the same procedure to compute the BPS ring structure of 2D $\mathcal{N} = (2, 2)$ theories using the exactly known results regarding the 2D sphere partition functions [6, 7, 8, 9]. In order for us to use the sphere partition function and still be able to infer results for the theory on flat space, we require that we must be able to canonically place the flat space theory on a sphere. This forces us to restrict to 2D $\mathcal{N} = (2, 2)$ theories that flow to some conformal theories. One interesting feature of these rings in 2D is that, unlike their 4D analogues, they are not freely generated, and our procedure will generate the ring relations. This process does not rely on Mirror symmetry and therefore results obtained in this way can be used for independent checks of such symmetry.

The plan for the rest of the paper is as follows. In §2 we establish the notations and conventions we use to characterize the BPS ring structures. In §3 we review, tailoring to the 2D case, the procedure put forward in [4] for computing chiral rings and finally in §4 we apply this general procedure to compute the twisted chiral ring (consisting of the Coulomb branch operators) of the Quintic Calabi-Yau gauged linear sigma model (GLSM) and the chiral ring of the Landau-Ginzburg (LG) minimal models. In the appendices we present details about the superconformal algebra (§A), supersymmetric...
backgrounds on the sphere (§B), proof of a supersymmetric Ward identity we use (§C), and some explicit computations (§D).

Note: After this paper was finished the paper [10] came out with which this paper has a large overlap.

2 The BPS Rings

We first give the definition of the BPS ring in a superconformal theory, and then explain its definition for an ultraviolet (UV) theory with a conformal fixed point. We have included some details about the relevant $(2,2)$ superconformal algebra $su(2|2)$ in appendix A.

In a superconformal theory

A superconformal primary operator is one that is annihilated by all the $S$-supersymmetries:

$$\mathcal{O} \text{ is a primary } \Leftrightarrow [S_{\pm}, \mathcal{O}] = [\overline{S}_{\pm}, \mathcal{O}] = 0. \quad (2.1)$$

The anti-commutation relations of the $(2, 2)$ superconformal algebra (A.5) allow to consistently define the following types of primary operators with additional supersymmetry:

| Type                      | Relations                          |
|---------------------------|------------------------------------|
| Chiral                    | $[\overline{Q}_{\pm}, \mathcal{O}] = 0, \quad (2.2a)$ |
| Anti-chiral               | $[Q_{\pm}, \mathcal{O}] = 0, \quad (2.2b)$ |
| Twisted chiral            | $[\overline{Q}_{+}, \mathcal{O}] = [Q_{-}, \mathcal{O}] = 0, \quad (2.2c)$ |
| Twisted anti-chiral       | $[Q_{+}, \mathcal{O}] = [\overline{Q}_{-}, \mathcal{O}] = 0. \quad (2.2d)$ |

Note that we use the name BPS (anti-BPS) to refer to both chiral and twisted chiral (anti-chiral and twisted anti-chiral). The above definitions apply to local and nonlocal operators alike but for this paper we are only concerned with local operators. Charges of chiral primaries under some of the generators of $su(2|2)$ are constrained: for example, using the $Q$-$S$ anti-commutators from (A.5) it follows that the dimension and vector R-charge of a chiral primary $\mathcal{O}$ are related, so are the dimension and the vector R-charge of an anti-chiral primary $\overline{\mathcal{O}}$:

$$2\Delta(\mathcal{O}) = J_V(\mathcal{O}), \quad 2\Delta(\overline{\mathcal{O}}) = -J_V(\overline{\mathcal{O}}). \quad (2.3)$$

Such constraints lead to non-singular operator product expansion (OPE) between chiral primaries [11]:

$$(\mathcal{O}_1 \mathcal{O}_2)(x) := \lim_{y \to x} \mathcal{O}_1(x) \mathcal{O}_2(y) =: \mathcal{O}_3(x), \quad (2.4)$$

where $\mathcal{O}_3$ is either zero or a chiral primary with dimension:

$$\Delta(\mathcal{O}_3) = \Delta(\mathcal{O}_1) + \Delta(\mathcal{O}_2). \quad (2.5)$$
With this product the set of all chiral primaries becomes a ring called the chiral ring, which we will denote as $\mathcal{R}^c$. The twisted chiral ring, denoted $\mathcal{R}^{tc}$, is analogously defined as the ring of twisted chiral primaries.

### Theories with conformal fixed points

The definition of primary operators (2.1) does not apply in a non-conformal theory since the $S$-supersymmetries are not part of the symmetry in such case, so the BPS rings can not be defined in such a theory as the ring generated by the primaries. There is however an alternative definition of these rings which applies in this case. For that definition we need the following two nilpotent supercharges:

$$Q_A := \overline{Q}_+ + Q_- , \quad Q_B := \overline{Q}_+ + \overline{Q}_- ,$$

$$Q_A^2 = 0 , \quad Q_B^2 = 0 .$$

(2.6)

Now the chiral (twisted chiral) ring can be defined as the $Q_B$-cohomology ($Q_A$-cohomology) of operators:

$$\mathcal{R}^c := H_{Q_B} , \quad \mathcal{R}^{tc} := H_{Q_A} ,$$

(2.7)

where the grading refers to the $U(1)_V$ R-charge for the chiral ring and the $U(1)_A$ R-charge for the twisted chiral ring.

To see that these cohomologies define the same ring as the ring of chiral/twisted chiral primaries in a superconformal theory we need the following two observations:

1. Suppose $\mathcal{O}$ is a $Q_B$-closed operator:

$$[\overline{Q}_+ + \overline{Q}_-, \mathcal{O}] = 0 .$$

(2.8)

If $\mathcal{O}$ has spin $^3 \alpha$ then rotating the above equation by an angle $\pi/2$ we get:

$$[-i\overline{Q}_+ + i\overline{Q}_-, e^{i\pi\alpha/2} \mathcal{O}] = 0$$

(2.9)

Together, (2.8) and (2.9) imply:

$$[\overline{Q}_+, \mathcal{O}] = [\overline{Q}_-, \mathcal{O}] = 0 .$$

(2.10)

Thus we recover the chirality condition (2.2a). Similarly it can be shown that being $Q_A$-closed is equivalent to being twisted chiral (2.2c).

2. Any chiral (twisted chiral) operator is $Q_B$-cohomologous ($Q_A$-cohomologous) to a chiral (twisted chiral) primary. Furthermore, a $Q_{A/B}$-exact operator is not a primary, since a primary is defined as the operator in a superconformal multiplet with the lowest Weyl weight, whereas an operator $[Q_{A/B}, \mathcal{O}]$ is in the same multiplet as $\mathcal{O}$ while having a higher Weyl weight than $\mathcal{O}$.

---

2 $Q_A$ and $Q_B$ have charge 1 under $U(1)_A$ and $U(1)_V$ respectively.

3 By spin we are referring to the charge for the generator $2J_L$ (where $J_L$ is the generator of rotation on $\mathbb{R}^2$), note that $\overline{Q}_\pm$ has charge $\mp 1$ for this generator. (Details about the symmetry algebra are provided in §A.)
The cohomological definition of the BPS rings (2.7) is perfectly sensible in the absence of conformal symmetry and coincides with the definition in terms of superconformal primaries at a conformal fixed point.

**Extremal correlators**

Let us first define extremal correlators in an SCFT, and then explain why we can compute them in a UV theory with CFT fixed point.

Given two BPS operators, \( O_1 \) and \( O_2 \) of conformal dimensions \( \Delta_1 \) and \( \Delta_2 \) respectively, the field theory defines a Hermitian inner product:

\[
\langle O_1, O_2 \rangle := \lim_{x \to \infty} |x|^{\Delta_1 + \Delta_2} \langle O_1(0) \overline{O}_2(x) \rangle_{\mathbb{R}^2} = \delta_{\Delta_1, \Delta_2} \lim_{x \to \infty} |x|^{2\Delta_2} \langle O_1(0) \overline{O}_2(x) \rangle_{\mathbb{R}^2},
\]  

(2.11)

where \( \overline{O}_2 \) is the anti-BPS primary operator conjugate to \( O_2 \). The second equality follows from \( U(1)_R \) selection rule \(^4\) and the constraint (2.3) (and its analogue for the twisted case). In order to shorten the notation of (2.11) we define:

\[
\overline{O}(\infty) := \lim_{x \to \infty} |x|^{2\Delta(O)} \overline{O}(x).
\]  

(2.12)

The inner product (2.11) now becomes:

\[
\langle O_1, O_2 \rangle = \langle O_1(0) \overline{O}_2(\infty) \rangle_{\mathbb{R}^2}.
\]  

(2.13)

The correlation functions of this form, i.e., with a BPS operator at 0 and an anti-BPS operator at \( \infty \), are called extremal correlators on \( \mathbb{R}^2 \).

There’s a little more to the extremal correlators. Generally they are defined with an arbitrary number of BPS primaries \( O_1, \ldots, O_m \) located at \( x_1, \ldots, x_m \) respectively and one anti-BPS primary at \( \infty \):

\[
\langle O_1(x_1) \cdots O_m(x_m) \overline{O}(\infty) \rangle_{\mathbb{R}^2},
\]  

(2.14)

and this correlator is independent of the positions \( x_1, \ldots, x_m \). We can see this by translating any of the BPS operators and using \[A.5\] for example, the infinitesimally translated correlator \( \langle [L_{-1}, O_1](x_1) \cdots O_m(x_m) \overline{O}(\infty) \rangle_{\mathbb{R}^2} \) is proportional to:

\[
\lim_{y \to \infty} |y|^{2\Delta(O)} \langle \{Q_+, \overline{Q}_+ \}, O_1(x_1) \cdots O_m(x_m) \overline{O}(y) \rangle_{\mathbb{R}^2}.
\]  

(2.15)

Supersymmetric Ward identity allows us to pull \( \overline{O}_+ \) out of \( O_1 \) and distribute it over the rest of the operators, all the BPS operators are annihilated by \( \overline{Q}_+ \) and when it acts on \( \overline{O} \), the correlator behaves as \( |y|^{-\Delta(O)} \) and the limit makes the contribution zero. This position independence of the extremal correlators allows us to bring all the chiral operators to one point (say at the origin).

---

\(^4\) \( U(1)_R = U(1)_V \) if the operators are chiral and \( U(1)_R = U(1)_A \) if the operators are twisted chiral.
A similar argument shows that exact operators are zero inside extremal correlators and therefore the extremal correlators really define an inner product in the cohomology. Furthermore, the energy-momentum tensor couples to the linearized space-time metric via a D-term action \[12\]. Variation of a correlation function with respect to the metric then inserts an operator inside the correlator which is an integral over the entire superspace:

\[
\delta g_{\mu\nu} \langle \cdots \rangle_{g^2} \sim \left( \int d^2\theta d^2\bar{\theta} \langle \cdots \rangle \right)_{g^2}
\]  

(2.16)

Such an integrated operator can be written as an exact operator \[13\] which implies that as long as \( \langle \cdots \rangle_{g^2} \) is an extremal correlator such variations vanish. This in particular implies that the extremal correlators are scale invariant, in other words, they are RG invariant and can be computed in a UV theory even when we are interested in an IR CFT fixed point.

**Basis, structure constants, norms and relations**

In a finitely and freely generated ring \[\mathcal{R}\] with a non-degenerate Hermitian inner product \( \langle -, - \rangle \), we can choose a minimal set of generators \( \{ O_1, O_2, \cdots, O_N \} \) and define a metric in their basis:

\[ g_{ij} := \langle O_i, O_j \rangle . \]  

(2.17)

The inverse metric \( g^{ij} \) is defined by imposing:

\[ g^{ij} g_{jk} = \delta^i_k, \quad g_{ij} g^{jk} = \delta^j_i . \]  

(2.18)

We define the ring structure by the structure constants in such a basis:

\[ O_i O_j = C_{ij}^k O_k \iff C_{ij}^k = C_{ij} g^{jk} \quad \text{where,} \quad C_{ij} := \langle O_i O_j, O_i \rangle \]  

(2.19)

Furthermore, we can choose the basis in such a way that the structure constants become trivial/diagonal in the following sense:

\[ C_{ij}^k = \delta_{i+j}^k . \]  

(2.20)

Now all the nontrivial information about the ring structure is encoded in the norms of the basis vectors:

\[ \| O_i \| := \sqrt{\langle O_i, O_i \rangle} . \]  

(2.21)

The constraint \[2.20\] fixes the norms of all the basis vectors relative to each other. To fix this arbitrariness in case of the BPS rings, we will fix the norm of the identity

---

5The 2D BPS rings are finitely but *not* freely generated, we will discuss truncation by relations momentarily.

6For two indices \( i \) and \( j \) referring to two operators \( O_i \) and \( O_j \), we use the index \( i+j \) to refer to the operator with dimension equal to the sum of the dimensions of \( O_i \) and \( O_j \). For simplicity we are assuming that there is only one such operator, having more does not make any qualitative difference.
operator $\mathbb{1}$ to be $1$:

$$\langle \mathbb{1}, \mathbb{1} \rangle := 1. \quad (2.22)$$

Given a complete set of generators $\{O_1, \cdots, O_N\}$, a freely generated ring is simply the polynomial ring:

$$\mathcal{R} = \mathbb{C}[O_1, \cdots, O_N]. \quad (2.23)$$

The only new addition to this discussion in the case of a ring with relations, is that there will be some polynomials $p_a \in \mathbb{C}[O_1, \cdots, O_N]$ for $a \in \{1, \cdots, M\}$ which will be identified with zero, i.e., we must impose the relations $p_a = 0$ for all $a \in \{1, \cdots, M\}$ and the ring will be given by:

$$\mathcal{R} = \mathbb{C}[O_1, \cdots, O_N]/\langle p_1, \cdots, p_M \rangle. \quad (2.24)$$

where $\langle p_1, \cdots, p_M \rangle$ is the ideal generated by the polynomials $\{p_1, \cdots, p_M\}$.

In the context of the 2D $\mathcal{N} = (2, 2)$ BPS rings, the zero polynomials will appear as BPS operators with zero norm. We will always choose a basis of the BPS operators with trivialized (as in (2.20)) structure constants and the identity operator will be defined to have unit norm, therefore, according to the above discussion all the information of the BPS rings will be encoded in the extremal correlators $\langle O_i(0)\overline{O}_j(\infty)\rangle_{\mathbb{R}^2}$, in particular, finding the relations will amount to finding BPS operators $\mathcal{O}$ such that $\langle O(0)\overline{O}(\infty)\rangle_{\mathbb{R}^2} = 0$.

### 3 Computing the Ring Structures

As explained in [2], a BPS ring structure is essentially defined by flat space extremal correlators $\langle O_i(0)\overline{O}_j(\infty)\rangle_{\mathbb{R}^2}$ of BPS primaries once a suitable basis has been chosen. A straightforward application of Weyl Ward identity tells us that if we put our theory on a sphere of radius $r$, then the extremal correlators on the sphere are related to the flat space correlators in the following way:

$$\langle O_i(0)\overline{O}_j(\infty)\rangle_{\mathbb{R}^2} = (2r)^{2\Delta(O)} \langle O_i(N)\overline{O}_j(S)\rangle_{S^2}, \quad (3.1)$$

where $N$ and $S$ on the sphere are images of 0 and $\infty$ on $\mathbb{R}^2$ respectively, under an inverse stereographic projection. The $S^2$ correlators that appear in the above formula can be readily computed using localization. The main complication then, in using the above formula to compute the BPS ring structure constants, is that the identification between the flat space operators and the operators on the sphere is nontrivial due to operator mixing on the sphere. Mixing among operators of different dimensions can

---

7 Note that $\|\mathbb{1}\|^2 = \langle \mathbb{1}(x)\mathbb{1}(\infty)\rangle_{\mathbb{R}^2} = Z$ where $Z$ is the partition function, therefore, in terms of Feynman diagrams, defining this norm to be one is equivalent to subtracting bubble diagrams from all our correlation functions.

8 The identification of zero normed operators with identically zero operators is provided by the Reeh-Schlieder theorem [14].
take place on the sphere because the sphere does not preserve scaling symmetry. Our task is therefore to “unmix” the operators on the sphere and then use the Weyl Ward identity \([3.1]\) to compute the BPS ring structures. In this section we elaborate on this general procedure. We note that this process is essentially identical to the process of computing chiral rings in 4D \(\mathcal{N} = 2\) SCFTs \([4]\).

### 3.1 Extremal Correlators on \(S^2\)

#### Choice of a localizing supercharge

The first step in extracting the flat space extremal correlators from the sphere partition function is to compute their analogue on the sphere, such as \(\langle O_i(N) O_j(S) \rangle_{S^2}^9\) using supersymmetric localization. We begin in this section by defining our choice of localizing supercharges for the two-sphere backgrounds described in §\(B\) and some of their important properties:

- **Background-A:** In accordance with the notation of §\(B\) we define our choice of localizing supercharge by imposing the following chirality constraints on the constant Dirac spinors that parametrize the solutions of the Killing spinor equations (see (B.4)):

  \[ \chi_{0-} = 0, \quad \bar{\chi}_{0+} = 0. \]  

(3.2)

With these constraints the Killing spinors become chiral at the poles:

\[ P_+ \epsilon^A_{\chi_0, \bar{\chi}_0} (N) = P_+ \bar{\epsilon}^A_{\chi_0, \bar{\chi}_0} (N) = 0, \quad P_+ \epsilon^A_{\chi_0, \bar{\chi}_0} (S) = P_+ \bar{\epsilon}^A_{\chi_0, \bar{\chi}_0} (S) = 0, \]  

(3.3)

where \(P_\pm := \frac{1}{2} (1 + \gamma^3)\) are the chiral projectors. We will refer to this choice of supercharge as \(Q_A\).

We recall that under a generic supercharge corresponding to a generic solution \(\epsilon\) and \(\bar{\epsilon}\) of the Killing spinor equations, a twisted chiral primary \(Y\) and a twisted anti-chiral primary \(Y\) of the Killing spinor equations, a twisted chiral primary \(Y\) and a twisted anti-chiral primary \(\bar{Y}\), which are the bottom components of a twisted chiral multiplet \((Y, \zeta, G)\) and a twisted anti-chiral multiplet \((\bar{Y}, \bar{\zeta}, \bar{G})\) respectively, transform as (C.1):

\[ \delta_{\epsilon, \bar{\epsilon}} Y(x) = \bar{\epsilon}_+ (x) \zeta_- (x) - \epsilon_- (x) \zeta_+ (x), \quad \delta_{\epsilon, \bar{\epsilon}} \bar{Y}(x) = \bar{\epsilon}_- (x) \zeta_+ (x) - \epsilon_+ (x) \zeta_- (x). \]  

(3.4)

Therefore, for the supercharge \(Q_A\) corresponding to (3.3) we get:

\[ \delta_{Q_A} Y(N) = \delta_{Q_A} \bar{Y}(S) = 0. \]  

(3.5)

This implies that insertions of twisted chiral and twisted anti-chiral primaries at the North and the South pole respectively are invariant under \(Q_A\) and the\(^9\)

---

9North \((N)\) and South \((S)\) poles refer to two antipodal points on the sphere. We will take them to be \(x = 0\) and \(x = \infty\) (in stereographic coordinate) for convenience.
corresponding correlators can be computed by supersymmetric localization using $Q_A$.\(^{10}\)

- **Background-B**: We impose the same chirality constraints \((3.2)\) on the constant spinors but this leads to different constraints for the Killing spinors of this background \((3.9)\):

$$
\tilde{\epsilon}^B_{\chi_0, \bar{\chi}_0}(N) = 0, \quad \epsilon^B_{\chi_0, \bar{\chi}_0}(S) = 0. \tag{3.6}
$$

We will refer to this choice of supercharge by $Q_B$.

We recall the transformations of a chiral primary $\phi$ and an anti-chiral primary $\bar{\phi}$, which are the bottom components of a chiral multiplet $(\phi, \psi, F)$ and an anti-chiral multiplet $(\bar{\phi}, \bar{\psi}, F)$ respectively, under a generic supercharge \([6]\):

$$
\delta_{\epsilon, \bar{\epsilon}} \phi(x) = \tilde{\epsilon}(x) \psi(x), \quad \delta_{\epsilon, \bar{\epsilon}} \bar{\phi}(x) = \epsilon(x) \bar{\psi}(x). \tag{3.7}
$$

Therefore, according to \((3.6)\) we have:

$$
\delta_{Q_B} \phi(N) = \delta_{Q_B} \phi(S) = 0, \tag{3.8}
$$

implying that we can compute correlators with insertions of chiral and anti-chiral primaries at the North and South pole respectively by supersymmetric localization using the supercharge $Q_B$.\(^{11}\)

**A Ward identity and extremal correlators**

A particularly convenient way to insert BPS (anti-BPS) primary operators at the North (South) pole of the sphere is to use a supersymmetric Ward identity. Before stating the identity, let us define for an arbitrary twisted chiral multiplet $\Psi = (Y, \zeta, G)$ with a scalar bottom component:

$$
G(\Psi) := G + \frac{\Delta(Y)}{r} - \frac{1}{r} Y, \tag{3.9}
$$

where $\Delta(Y)$ denotes the Weyl weight (equal to the dimension for a scalar operator) of $Y$. Now we state the Ward identity:

Suppose we are given the following data in background-A: A supercharge $Q_A \in su(2|1)_A$, a $Q_A$-invariant operator\(^{12}\) $O$ and a twisted chiral multiplet $\Psi = (Y, \zeta, G)$ of arbitrary Weyl weight. Then, inside a correlator with $O$, the $su(2|1)_A$-invariant twisted F-term action for $\Psi$ localizes to the insertion

---

\(^{10}\)Such a supercharge was used in \([3]\) to compute the $su(2|1)_A$-invariant partition function using localization.

\(^{11}\)Such a supercharge was used in \([8]\) to compute $su(2|1)_B$-invariant partition function and correlation functions of 2D gauge theories.

\(^{12}\)The operator $O$ does not have to be twisted chiral, it suffices that $\langle O \rangle_{S^2}$ be an extremal correlator.
of the bottom component $Y$ at the fixed point of $Q_A$ on the sphere (which we call the North pole $N$), in other words:

$$\left\langle \left( \int_{S^2} d^2x \sqrt{g(x)} \mathcal{G}(\Psi) \right) \mathcal{O} \right\rangle_{S^2} = -4\pi r \langle Y(N)\mathcal{O} \rangle,$$

(3.10)

where $g$ is the determinant of the covariant metric on the sphere. Similarly, the conjugate twisted F-term action of the twisted anti-chiral multiplet $\bar{\Psi} = (\bar{Y}, \bar{\zeta}, \bar{G})$ localizes to the insertion of the bottom component at the South pole (fixed point of $Q_A$):

$$\left\langle \left( \int_{S^2} d^2x \sqrt{g(x)} \mathcal{G}(\bar{\Psi}) \right) \mathcal{O} \right\rangle_{S^2} = 4\pi r \langle Y(S)\mathcal{O} \rangle.$$

(3.11)

There is a parallel Ward identity for background-B the statement of which simply replaces $Q_A$ with $Q_B$ and “twisted chiral” with “chiral”. In [15] this was proven for twisted chiral multiplets in background-A and chiral multiplets in background-B of Weyl weight 1.\(^{13}\) The proof for arbitrary Weyl weight requires only a trivial modification, we reproduce the modified proof in §C for reference.

The twisted F-terms or the F-terms can be used to deform the theory\(^{14}\) in background-A or B respectively by introducing coupling constants of appropriate Weyl weights. For example, in background-A we can have the following deformation:\(^{15}\)

$$S_A[X] \rightarrow S'_A[X; \tau, \bar{\tau}] := S_A[X] + \left[ -\frac{i\tau}{4\pi} \int_{S^2} d^2x \sqrt{g(x)} \mathcal{G} + \text{c.c.} \right],$$

(3.12)

where the bottom component $Y$ of the twisted chiral multiplet $\Psi = (Y, \zeta, G)$ and the coupling constant $\tau$ have Weyl weights that satisfy:

$$\Delta(Y) + \Delta(\tau) = 1,$$

(3.13)

and $X$ is merely a place-holder for all the dynamical fields. Using the Ward identities \((3.10)\) and \((3.11)\) we can now relate $\tau$-derivatives of the partition function to extremal correlators:

$$\frac{1}{Z_{S^2}^A} \frac{1}{r^{m+n}} \partial^m_\tau \partial^n_{\bar{\tau}} Z_{S^2}^A(\tau, \bar{\tau}) \big|_{\tau, \bar{\tau} = 0} = \left\langle (iY)^m(N)(i\bar{Y})^n(S) \right\rangle_{S^2},$$

(3.14)

where $Z_{S^2}^A(\tau, \bar{\tau})$ is the deformed partition function:\(^{16}\)

$$Z_{S^2}^A(\tau, \bar{\tau}) = \int \mathcal{D}X \ e^{-S'_A[X; \tau, \bar{\tau}]}.$$
We encode the equation (3.14) in the following correspondence between derivative with respect to a coupling, and the operator it inserts at a pole after localization:

\[ \frac{1}{r} \partial_r \leftrightarrow i Y(N), \quad \frac{1}{r} \partial_r \leftrightarrow i Y(S). \]  

(3.16)

We can compute extremal correlators of chiral operators on the sphere similarly in background-B.

**Remark:** If the undeformed action already contains a superpotential or twisted superpotential coupling then we can compute extremal correlators of the corresponding chiral or twisted chiral fields without any further deformation, just by taking derivatives with respect to the corresponding coupling constant. An example of this, which will be studied in detail later, is an abelian gauge theory in background-A where the action contains a complexified Fayet-Iliopoulos (FI) coupling \( t \int_{S^2} d^2 x \sqrt{g(x)} G_\Sigma \) where \( G_\Sigma \) is the top component of a twisted chiral multiplet \( \Sigma \) of Weyl weight\(^{17}\) 1 known as the field strength multiplet. The bottom component of this multiplet is a complex scalar \( \sigma \) and we can therefore compute such extremal correlators as \( \langle \sigma^m(N) \bar{\sigma}^n(S) \rangle_{S^2} \) by evaluating derivatives of the partition function with respect to the FI parameters \( t \) and \( \bar{t} \) at arbitrary values of \( t \) and \( \bar{t} \). We will do this in \( \S 4.1 \).

### 3.2 Chiral Ring Coefficients from Extremal Correlators on \( S^2 \)

Knowing the extremal correlators on \( S^2 \), the next step is to extract from them the flat space extremal correlators.

**Operator mixing**

As was pointed out in \cite{4} for the case of 4D \( \mathcal{N} = 2 \) SCFTs, when put on a sphere, operators of different Weyl weights can mix due to the presence of scheme dependent Weyl symmetry breaking counterterms. This is true in two dimensions as well. The important difference between the two and four dimensional story is that, in four dimensions the \( \mathcal{N} = 2 \) supergravity background multiplet that goes into the counterterms causing the operator mixing had Weyl weight 2, whereas the \( \mathcal{N} = (2, 2) \) supergravity background multiplet in two dimensions responsible for operator mixing has Weyl weight 1. This leads to the fact that in four dimensions two operators can mix on the sphere only if their Weyl weights differ by an even integer, on the other hand in two dimensions two operators with Weyl weights differing by any integer amount can mix.

More specifically, on \( S^2 \), a chiral (twisted chiral) operator \( O_w \) of Weyl weight \( w \) can

---

\(^{17}\)By the Weyl weight of a BPS multiplet we refer to the Weyl weight of its bottom component. In particular, by a twisted chiral multiplet \( \Psi = (Y, \zeta, G) \) of Weyl weight \( w \) we mean that \( Y \) has Weyl weight \( w \). The Weyl weights of \( \zeta \) and \( G \) are \( (w + \frac{1}{2}) \) and \( (w + 1) \) respectively.
mix with all chiral (twisted chiral) operators of lower weights\(^{18}\)

\[
O_w \rightarrow O_w + \sum_{n \in \mathbb{N}} \alpha_n (\tau_{\text{mar}})^r r^{-n} O_{w-n}, \tag{3.17}
\]

where the mixing coefficients \(\alpha_n\) are arbitrary holomorphic functions of all the exactly marginal couplings, schematically written as \(\tau_{\text{mar}}\). We now construct the \(\mathcal{N} = (2,2)\) supergravity counterterms giving rise to such mixings.

There are two minimal versions of \(\mathcal{N} = (2,2)\) supergravity that differ in the choice of \(U(1)\) R-symmetry that is gauged\(^ {16, 17, 18, 19, 12, 20}\). After choosing appropriate background values for the fields, these two versions reduce to background-A and background-B on \(S^2\) preserving the vector and the axial R-symmetry respectively. Let us focus on the supergravity leading to background-A.

We discuss the mixing of the bottom component of a twisted chiral multiplet \(\tilde{\Omega}_w = (O_w, \zeta_{O_w}, G_{O_w})\) of Weyl weight \(w\). In order to compute correlation functions of the operator \(O_w\) using the Ward identity \((3.10)\) we need to deform the action, as in \((3.12)\), by introducing a coupling. The manifestly supersymmetric way of doing this is to use superspace integrals to write the deformation terms. To that end we need to promote the coupling, which we denote as \(\tau\) (making the Weyl weight explicit), to the bottom component of a background twisted chiral multiplet \(\tilde{\tau}_{\text{1-w}} = (\tau_{\text{1-w}}, \zeta_{\tau_{\text{1-w}}}, G_{\tau_{\text{1-w}}})\). For this background multiplet to be supersymmetric, the \(su(2|1)\) variations of the component fields must vanish. Consulting \((C.1)\) we find the following background values for the fermion and the top component (given the constant value of the bottom component):

\[
\zeta_{\tau_{\text{1-w}}} = 0, \quad G_{\tau_{\text{1-w}}} = \frac{w-1}{r} \tau_{\text{1-w}}. \tag{3.18}
\]

Now the superspace integral representation of the deformation \((3.12)\) becomes\(^ {19}\)

\[
- \frac{i \tau_{\text{1-w}}}{4\pi} I_{w,0} := - \frac{i}{4\pi} \int_{S^2} d^2 \Theta \mathcal{E}_{tc} \tilde{\tau}_{\text{1-w}} \tilde{\Omega}_w = - \frac{i \tau_{\text{1-w}}}{4\pi} \int_{S^2} d^2 x \sqrt{g(x)} G(\tilde{\Omega}_w). \tag{3.19}
\]

\(^{18}\)In the sum we are restricting to lower weights to avoid repeated counting, since mixing with an operator of higher weight is already considered as a mixing of the higher weighted operator with the lower weighted operator. Also, we are assuming that there is at most one operator with a given Weyl weight for simplicity. If there are more than one operators of a given Weyl weight then we only need to choose an ordering of these operators and all the computations follow without any qualitative modification.

\(^{19}\)The equality in \((3.19)\) can be proven as follows. For a twisted chiral multiplet \(\Psi_1 = (Y, \zeta, G)\) of Weyl weight \(w = 1\), the relevant superspace integral just picks up the top component, i.e.,

\[
\int_{S^2} d^2 x \int d^2 \tilde{\Theta} \mathcal{E}_{tc} \Psi_1 = \int_{S^2} d^2 x \sqrt{g(x)} G. \]

That this is supersymmetric can also be checked by noting that the \(su(2|1)\) variation of \(G\), namely \(\delta G = \nabla_m (i \tilde{\tau} \gamma^m \zeta - i \gamma^m \zeta)\) (see \((C.1)\)), is a total derivative. Now assume \(\Psi_w = (Y, \zeta, G)\) is a twisted chiral multiplet of some arbitrary Weyl weight \(w\) and \(\tilde{\tau}_{\text{1-w}} = (\tau, 0, \frac{w-1}{r} \tau)\) is a supersymmetric background twisted chiral multiplet of Weyl weight \((1-w)\). Then \(\tilde{\tau}_{\text{1-w}} \Psi_w = (\tau Y, \tau \zeta, \tau (G + \frac{w-1}{r} Y))\) \(^ {12}\) is a twisted chiral multiplet of Weyl weight 1 and therefore

\[
\int_{S^2} d^2 x \int d^2 \tilde{\Theta} \mathcal{E}_{tc} \tilde{\tau}_{\text{1-w}} \Psi_w = \int_{S^2} d^2 x \sqrt{g(x)} \left( \tau \left(G + \frac{w-1}{r} Y\right)\right), \]

and it is supersymmetric.
where, as in the definition (3.9), \( G(\Psi) = G + \frac{w-1}{r} Y \). The supergravity counterterm that leads to the mixing of the operator \( O_w \) with another twisted chiral operator \( O_{w-n} \) of lower weight \( (n \in \mathbb{N}_{>0}) \) necessarily involves the background coupling multiplet \( \tilde{\tau}_{1-w} \), the twisted chiral multiplet \( \tilde{O}_{w-n} := (O_{w-n}, \zeta_{O_{w-n}}, G_{O_{w-n}}) \) of weight \( (w-n) \) and a background twisted chiral multiplet \( \tilde{M} = (M, \zeta_R, -\mathcal{R}/2) \) whose bottom component is a complex scalar of Weyl weight 1 coming from the supergravity multiplet and whose top component is proportional to the scalar curvature of the space-time (this multiplet appeared in [21] in the context of 2D supergravity and in [15] in constructing supergravity counterterms responsible for Kähler ambiguity in two-sphere partition function). On the sphere background, the scalar curvature is \( \mathcal{R} = \frac{2}{r^2} \). As we did for the background coupling multiplet \( \tilde{\tau}_{1-w} \), we now find the supersymmetric background values for the component fields of \( \tilde{M} \) (this time given the constant value of the top component):

\[
M = \frac{1}{r}, \quad \zeta_R = 0, \quad -\frac{\mathcal{R}}{2} = -\frac{1}{r^2}.
\]  

(3.20)

Apart from the multiplets just mentioned, we have the freedom to include an arbitrary holomorphic function \( \alpha \) of the exactly marginal couplings \( \tau_{\text{mar}} \), including this we can now write down the mixing counterterm:

\[
-i \frac{\tau_{1-w}}{4\pi} I_{w,n} := -i \frac{1}{4\pi} \int_{S^2} d^2x \int d^2\tilde{\theta} \mathcal{E}_{\text{tc}} \tilde{\tau}_{1-w} \alpha(\tilde{\tau}_{\text{mar}}) \tilde{M}^n \tilde{O}_{w-n},
\]  

(3.21)

where we have promoted the exactly marginal couplings to background twisted chiral multiplets of Weyl weight 0. Just to avoid cluttering the notation too much, let us introduce a symbol for the product multiplet:

\[
\tilde{O}_{w,n}^\alpha := \alpha(\tilde{\tau}_{\text{mar}}) \tilde{M}^n \tilde{O}_{w-n}.
\]  

(3.22)

Since this is a multiplet of Weyl weight \( w \), we can use (3.19) to evaluate the superspace integral in (3.21) which leads to:

\[
I_{w,n} = \int_{S^2} d^2x \sqrt{g(x)} G(\tilde{O}_{w,n}^\alpha).
\]  

(3.23)

The Ward identity (3.10) tells us that, inside an extremal correlator, the integrated operator \( I_{w,n} \) will localize to the insertion of the bottom component of \( \tilde{O}_{w,n}^\alpha \) at the North pole. The bottom component of a product multiplet is simply the product of the bottom components of the individual multiplets in the product [12]. Therefore, in presence of the counterterm (3.23), the correspondence between coupling derivatives and operators (3.16) is modified:

\[
\frac{1}{r} \partial_{\tau_{1-w}} \leftrightarrow i O_w(N) + i\alpha(\tau_{\text{mar}}) r^{-n} O_{w-n}(N).
\]  

(3.24)

In general, we must consider all possible counterterms, \( \tau_{1-w} I_{w,n} \) for all \( n \in \mathbb{N} \) with \( 0 < n \leq w \) and this leads to the general form of the mixing (3.17).
“Un-mixing” the operators

Let us define $O_w$ to be the mixed operator in (3.17):

$$O_w := O_w + \sum_{n \in \mathbb{N}} \alpha_n(\tau_{\text{mar}}) r^{-n} O_{w-n} \quad \Rightarrow \quad \frac{1}{r} \partial_{\tau_{1-w}} \leftrightarrow iO_w. \quad (3.25)$$

Note that the mixing coefficients are scheme dependent, so these operators are not physical. But due to the mixing counterterms, such as (3.23), taking derivatives of the deformed sphere partition function with respect to the coupling constants computes extremal correlation functions of these operators:

$$\frac{1}{Z_{S^2}^A} \frac{1}{r^2} \partial_{\tau_{1-w}} \partial_{\tau_{1-w}'} Z_{S^2}^A |_{\tau_{1-w}=\tau_{1-w}'=0} = \langle iO_w(N) i\overline{O}_{w'}(S) \rangle_{S^2}. \quad (3.26)$$

We are of course interested in the flat space correlation functions of the physical operators, such as $\langle O_w(0) O_{w'}(\infty) \rangle_{\mathbb{R}^2}$. Once we properly identify the flat space operators with their counterparts on the sphere, we can relate the correlators on $\mathbb{R}^2$ with the correlators on $S^2$ by the Weyl Ward identity (3.1).

On flat space, operators of different Weyl weights are orthogonal, this changes on the sphere. It is a standard procedure to compute the inner products in an orthogonal basis (the $O_w$’s) given the inner products in the mixed basis (the $\mathcal{O}_w$’s), called the Gram-Schmidt procedure. In order to state the result, it is convenient to define some matrices. Given a complete set of operators $\{\mathcal{O}_w\}$ indexed by their Weyl weights, define the following matrices:

$$M(\omega) := \begin{pmatrix} M_{0,0} & \cdots & M_{0,w} \\ \vdots & \ddots & \vdots \\ M_{w,0} & \cdots & M_{w,w} \end{pmatrix}, \quad M_{i,j} := \langle i\mathcal{O}_i(N) i\overline{O}_j(S) \rangle_{S^2}. \quad (3.27)$$

Now, we can express the flat space correlators of interest as follows (for $w \geq w'$):

$$\langle iO_w(0) i\overline{O}_{w'}(\infty) \rangle_{\mathbb{R}^2} = \delta_{w,w'} (2r)^{2w'} \frac{\det M(\omega)}{\det M(\omega-1)}. \quad (3.28)$$

We will use this formula in examples to compute chiral and twisted chiral ring relations in the following section.

---

20 A choice of scheme is a choice of the holomorphic functions $\alpha_n$ of the exactly marginal couplings.

21 For example, if $\tau$ is an exactly marginal coupling then the partition function $Z_{S^2}(\tau, \tau)$ depends on it and has a nonzero derivative: $\frac{1}{Z_{S^2}(\tau, \tau)} \partial_\tau Z_{S^2}(\tau, \tau) = \langle O_\tau \rangle_{S^2}$. Here $O_\tau$ is the bottom component of a BPS multiplet whose top component is an exactly marginal operator of Weyl weight 2. The bottom component $O_\tau$ has Weyl weight 1 and the fact that it has a nonzero one-point function indicates that it has mixed with the identity operator (of Weyl weight 0).
4 Some Examples

In this section we illustrate the general points made so far by applying them to a couple of well known $\mathcal{N} = (2, 2)$ theories, namely the Quintic GLSM and Landau-Ginzburg minimal models.

4.1 Twisted Chiral Ring of the Quintic GLSM

This is a $U(1)$ gauge theory with $\mathcal{N} = (2, 2)$ supersymmetry and the bosonic global symmetry is $U(1)_L \times U(1)_V \times U(1)_A$, where $U(1)_L$ is the spacetime rotation and $U(1)_V, U(1)_A$ are the vector and axial R-symmetries respectively. It is a theory of six chiral multiplets $\Phi_i$ with $i \in \{1, \cdots, 6\}$ interacting via a superpotential:

$$W(\Phi_1, \cdots, \Phi_6) = \Phi_6 P(\Phi_1, \cdots, \Phi_5),$$

where $P$ is a homogeneous polynomial of degree five. We will denote the vector multiplet by $V$ and the associated twisted chiral "field strength" multiplet is defined as (in superfield notation):

$$\Sigma := \overline{D}_+ D_- V,$$

where $\overline{D}_+$ and $D_-$ are two of the four superspace derivatives that commute with the supercharges. $\Sigma$ has Weyl weight $^{22}$ and its top component is $D - iF_{12}$, where $D$ is the real scalar in $V$ and $F_{12}$ is the field strength of the gauge field in $V$. This field strength multiplet defines the twisted superpotential action $^{23}$

$$-\frac{t}{4\pi} \int_{\mathbb{R}^2} d^2x \int d\theta^+ d\overline{\theta}^- \Sigma - c.c. = -\frac{i}{2\pi} \int_{S^2} d^2x \left( \xi D - \frac{\theta}{2\pi} F_{12} \right),$$

where $\xi$ and $\theta$ are the real FI parameter and the topological theta angle respectively:

$$t = i\xi + \frac{\theta}{2\pi}. \quad (4.4)$$

Charges of the fields of this theory under the gauge and the global symmetries are as follows (we have also included the charges of the superspace coordinates for quick

---

$^{22}$The kinetic term for the vector multiplet is normalized as $\frac{1}{e^2} \int d^2x d^2\theta d^2\overline{\theta} \Sigma \overline{\Sigma}$ where $e$ is the gauge coupling of dimension 1.

$^{23}$Our normalization of this term has an extra factor of $\frac{1}{2\pi}$ compared to that of [6, 9].
This model gets its name from the fact that for the value of the real FI parameter in a certain range (namely $\xi \gg 0$), the IR CFT fixed point of this theory is described by a non-linear sigma model with target \[3\]:

$$\Sigma = \Phi_6 = 0,$$

\[
\left\{ \sum_{i=1}^{5} |\Phi_i|^2 = \Im t \right\} / U(1)_{\text{gauge}} \cap \{ P(\Phi_1, \cdots, \Phi_5) = 0 \},
\]

which is known as the Quintic Calabi-Yau (CY) threefold\[25\].

**Twisted chiral ring**

The twisted chiral ring $\mathcal{R}^{tc}$ of this theory is generated by the complex scalar operator $\sigma$, which is the bottom component of the field strength multiplet $\Sigma$. An orthogonal spanning set for $\mathcal{R}^{tc}$ is given by $\{ \sigma^m \}_{m=0}^{\infty}$. This set also satisfies the triviality constraint for the structure constants (2.20) since we have:

$$\sigma^m \sigma^n = \sigma^{m+n}. \quad (4.7)$$

Therefore, after fixing the norm of $\sigma^0 = 1$ to be 1, all we have left to compute to determine $\mathcal{R}^{tc}$ are the following extremal correlators:

$$||\sigma^m||^2 = \langle \sigma^m(0)\sigma^m(\infty) \rangle_{\mathbb{R}^2} \quad \forall m \geq 0. \quad (4.8)$$

In the following we will compute these correlation functions and we will find that $\mathcal{R}^{tc}$ is not freely generated, we will find the null operators as well.

---

\[24\]The charges of the fields follow from the following arguments. The chiral fields appear in the action in the term $\int d^2x \int d\theta^+ d\bar{\theta}^- \Phi_6 P(\Phi_1, \cdots, \Phi_5)$ and the twisted chiral field appears in $\int d^2x \int d\theta^+ \bar{\theta}^- \Sigma$ and these terms have to be neutral. The bosonic measure is neutral under all the symmetry groups. Noting that $\theta$ and $d\theta$ have opposite charges we see that the fermionic measure $d\theta^+ d\theta^-$ has charge $(0, 0, -2, 0)$ under $U(1)_L \times U(1)_{\text{gauge}} \times U(1)_V \times U(1)_A$, and $d\theta^+ d\bar{\theta}^-$ has charge $(0, 0, 0, -2)$ under the same group.

\[25\]At the conformal fixed point the target space metric (i.e., the metric that appears in the kinetic term of the non-linear sigma model) is necessarily the Ricci flat metric.

\[26\]It should be noted that the non linear sigma model description in the IR Calabi-Yau phase of this GLSM contains more twisted chiral operators which are fermionic. These are the operators that survive the A-twist \[2\]. However, the description of these operators in the GLSM is unclear. We thank Cyril Closset for pointing out this subtlety.
From sphere to flat space

Extremal correlators of twisted chiral operators on the sphere can be computed by putting the theory in background-A (see §3.1). The partition function of a generic $\mathcal{N} = (2, 2)$ gauge theory in background-A has been computed explicitly in [6, 9] and this result has been applied to the specific case of the Quintic GLSM (among several others) in [22].

In the computation of the partition function in background-A, we can ignore the superpotential and only the twisted superpotential is important. The twisted superpotential action (4.3) of the theory gets modified in the sphere background by the appearance of nontrivial integration measures:

$$-\frac{1}{4\pi} \int_{S^2} d^2x \int d^2\tilde{\theta} E_{tc} t \Sigma - \text{c.c.} = -\frac{t}{4\pi} \int_{S^2} d^2x \sqrt{g(x)} G(\Sigma) - \text{c.c.}, \quad (4.9)$$

This being the only twisted superpotential of the theory, the $su(2|1)_A$ preserving partition function $Z^A_{S^2}(t, \bar{t})$ for the Quintic is a function only of the complexified FI parameter. Due to the presence of mixing counterterms (see (3.23)), derivatives of the partition function $Z^A_{S^2}(t, \bar{t})$ compute correlation functions of mixed operators. We denote these mixed operators as $s_m := \sigma_m + \mathcal{O}(r^{-1})$ (c.f. (3.25)) so that $t$ and $\bar{t}$-derivatives of $Z^A_{S^2}$ can be equated readily with correlation functions of $s_m$ and $s_n$ (c.f. (3.26)):

$$\frac{1}{r^{m+n}} Z^A_{S^2} \partial_t^m \partial_{\bar{t}}^n Z^A_{S^2}(t, \bar{t}) = \langle s_m(N) s_n(S) \rangle_{S^2}. \quad (4.10)$$

According to (3.28), in terms of these correlators, the extremal correlators on the flat space are given by:

$$\langle \sigma^m(0) \bar{\sigma}^n(\infty) \rangle_{R^2} = \delta_{m,n} \frac{(2\pi)^{2n}}{Z^A_{S^2}} \det_{i,j \in \{0, \ldots, m\}} \partial_i^t \partial_{\bar{t}}^j Z^A_{S^2}. \quad (4.11)$$

From now on we will set the radius of the sphere to 1 for simplicity.

The partition function $Z^A_{S^2}(t, \bar{t})$ does not depend on the axial R-charges, so instead of writing $qV$ all the time we will simply write $q$. For $\xi \gg 0$, the partition function can be written as [22]:

$$Z^A_{S^2}(t, \bar{t}) = (w \bar{w})^q \int \frac{d\epsilon}{2\pi i} (w \bar{w})^{-\epsilon} \pi^4 \sin(5\pi\epsilon) \left| \sum_{k=0}^{\infty} (-w)^k \frac{\Gamma(1 + 5k - 5\epsilon)}{\Gamma(1 + k - \epsilon)^5} \right|^2, \quad (4.12)$$

where we have defined:

$$w := e^{it}. \quad (4.13)$$

27These localization results were further extended to extremal correlators on $S^2$ and used to find evidence for Seiberg-like dualities for $(2, 2)$ gauge theories [9, 6, 23].

28There is again a factor of $2\pi$ offset with respect to the convention of [22], where they use $e^{2\pi it}$. This offset compensates for our choice of normalization in (4.3).
In (4.12), the contour surrounds only the pole at $\epsilon = 0$ and in computing the absolute value of the infinite sum complex conjugation does not act on $\epsilon$. The infinite sum appearing in (4.12) converges at $\epsilon = 0$ for large enough $\xi$, as can be seen from ratio test:

$$
\lambda_k := (-w)^k \frac{\Gamma(1 + 5k)}{\Gamma(1 + k)^5}, \quad \frac{\lambda_{k+1}}{\lambda_k} \xrightarrow{k \to \infty} -e^{\frac{4\pi}{5}\xi} \xi \to 0. \quad (4.14)
$$

Let us denote the series at $\epsilon = 0$ as:

$$
X(t) := \sum_{k=0}^{\infty} (-e^{it})^k \frac{\Gamma(1 + 5k)}{\Gamma(1 + k)^5}. \quad (4.15)
$$

The residue of the integrand at the pole is:

$$
\text{Res}_{\epsilon=0} \left( \frac{w \epsilon^{-\epsilon}}{2\pi i} \frac{\pi^4 \sin(5\pi \epsilon)}{\sin^5(\pi \epsilon)} \right) \left| \sum_{k=0}^{\infty} (-w)^k \frac{\Gamma(1 + 5k - 5\epsilon)}{\Gamma(1 + k - \epsilon)^5} \right|^2 = -\frac{10}{3\pi} i\xi(-5\pi^2 + \xi^2)X(t)X(t). \quad (4.16)
$$

Therefore the partition function as a function of the FI parameter looks like:

$$
Z_{A_{S^2}}(t, \bar{t}) = \frac{20}{3} e^{-2q\xi(-5\pi^2 + \xi^2)}X(t)X(t). \quad (4.17)
$$

One interpretation of this partition function is that it computes the Kähler potential of the moduli space of CFTs that can be reached from the GLSM under RG flow by varying the FI parameter \[15\]:

$$
Z_{A_{S^2}}(t, \bar{t}) = e^{-K(t, \bar{t})}. \quad (4.18)
$$

From this perspective, the partition function is defined only up to a Kähler transformation of the Kähler potential:

$$
K(t, \bar{t}) \to K(t, \bar{t}) + F(t) + \bar{F}(\bar{t}), \quad (4.19)
$$

where $F$ and $\bar{F}$ are arbitrary holomorphic and anti-holomorphic functions (in particular, they can be taken as $F = \log X$, $\bar{F} = \log \bar{X}$), and a Kähler transformation can be interpreted as a change of the UV regularization scheme \[15\], which does not affect any physical observables\[29\]. We now go to a simpler scheme by doing a Kähler transformation:

$$
Z_{A_{S^2}}(t, \bar{t}) \to \bar{Z}_{A_{S^2}}(t, \bar{t}) := \frac{Z_{A_{S^2}}(t, \bar{t})}{X(t)\bar{X}(\bar{t})} = \frac{20}{3} e^{-2q\xi(-5\pi^2 + \xi^2)}. \quad (4.20)
$$

Using $\partial_t = -\frac{i}{2} \partial_k + \pi \partial_\theta$ and $\partial_{\bar{t}} = \frac{i}{2} \partial_k + \pi \partial_\bar{\theta}$ we can now compute flat space correlation functions using $\bar{Z}_{A_{S^2}}$ in (4.11). Next we find the ring relations.

\[29\] A careful proof of the fact that a Kähler transformation does not affect the extremal correlators on flat space, in the analogous situation of 4D $\mathcal{N} = 2$ SCFTs, can be found in the appendix of \[4\], the proof applies without any significant change to the 2D case as well.
Relations and the ring

The correlation functions (4.10) are the matrix components from (3.27):

\[
M_{m,n} = \langle \sigma_m(N) \bar{\sigma}_n(S) \rangle_{S^2} = \frac{\partial^m \partial^n \tilde{Z}^A_{S^2}}{\tilde{Z}^A_{S^2}} = (-1)^m (i/2)^{m+n} \frac{\partial^{m+n} \tilde{Z}^A_{S^2}}{\tilde{Z}^A_{S^2}},
\]

where we could replace all the \( t \) and \( \tilde{t} \)-derivatives with \( \xi \)-derivatives because the partition function does not depend on the theta angle. Now the flat space correlators are given by:

\[
\langle \sigma^m(0) \sigma^n(\infty) \rangle_{\mathbb{R}^2} = \delta_{m,n} 2^{2n} \frac{\det M(m)}{\det M(m-1)}.
\]

We can get a recursion relation for \( m > 3 \) and \( n \geq 0 \):

\[
M_{m,n} = \frac{20}{3\tilde{Z}^A_{S^2}} (-1)^m (i/2)^{m+n} \sum_{k=0}^{3} (-2q)^{m+n-k} e^{-2q\xi} \partial^k_{\xi} (-5\pi^2 \xi + \xi^3) = iq M_{m-1,n}.
\]

This shows that for \( m > 3 \) the last \( (m-2) \) rows of the matrix \( M(m) \) are multiples of each other and therefore \( M(m) \) has \( (m-3) \) zero eigenvalues, i.e., \( \det M(m) \sim 0^{m-3} \). For the correlation functions the implication is:

\[
\frac{0^{m-3}}{0^{m-4}} \sim \langle \sigma^m(0) \bar{\sigma}^m(\infty) \rangle_{\mathbb{R}^2} = 0, \quad \forall m > 3.
\]

Since the above correlation function is equivalent to an operator norm in a unitary theory, the operators \( \sigma^m \) for \( m > 3 \) themselves are identically zero. Thus we have fully determined the ring:

\[
\text{Twisted chiral ring for the Quintic, } \mathcal{R}^{tc} = \mathbb{C}[\sigma]/\langle \sigma^4 \rangle.
\]

This result was previously obtained in \cite{24,25} using the topologically A-twisted version of the GLSM which doesn’t require the supersymmetric localization and the counterterm analysis that we did. The upshot of going through the more elaborate method that we have presented is that this allows us to see the change in the ring structure as we move along the CFT moduli space; which we now discuss.

Toda and \( tt^\ast \)-geometry of the bundle of BPS primaries

The nontrivial coupling dependence of the extremal correlators\(^\text{30}\) can be given a geometric interpretation \cite{26}, where we view the twisted chiral primaries as forming a holomorphic bundle with nontrivial connection over the conformal manifold parametrized by the exactly marginal coupling constants, the FI parameter in the present case. More

\(^\text{30}\)the coupling dependence of the correlators (4.22) derives from the coupling dependence of the partition function (4.20) via (4.21).
generally, this picture applies to both chiral and twisted chiral rings in CFTs with arbitrary dimensional conformal manifolds. The CFT dynamics imposes the following curvature constraints (a.k.a. the $tt^*$ equations) on the geometry of these bundles:

\[ \left[ \nabla_\mu, \nabla_\nu \right] j_i = \left[ \nabla_\mu, \overline{\nabla}_\nu \right] j_i = 0 \quad (4.26a) \]

\[ \left[ \nabla_\mu, \overline{\nabla}_\nu \right] j_i = -\left[ C_\mu, \overline{C}_\nu \right] j_i + g_{\mu\nu} \delta^j_i \left( 1 + \frac{R}{4c} \right) . \quad (4.26b) \]

Let us explain the notations: $\mu, \nu$ refer to tangential directions on the conformal manifold and $i, j$ refer to all BPS primaries. A bar over an index corresponds to an anti-BPS primary. In the second line, $R$ is the $U(1)_R$ charge of the bundle and $c$ is the central charge of the CFT. The matrices $C_\mu$, or more generally $C_i$, with indices expressed as $C_{ij}^k$ are the structure constants of our ring as defined in (2.19), and finally, the metric $g_{\mu\nu}$, or more generally $g_{ij}$, is defined in terms of extremal correlators as in (2.17).

With a suitable choice for the basis of the BPS primaries over the conformal manifold, the $tt^*$ equation (4.26b) can be put into a more explicit form:

\[ \frac{\partial}{\partial \tau^\mu} \left( g^{kj} \frac{\partial}{\partial \tau^\nu} g_{ik} \right) = \left[ C_\mu, \overline{C}_\nu \right] j_i - g_{\mu\nu} \delta^j_i . \quad (4.27) \]

Specializing to the case of a one dimensional conformal manifold, such as the Quintic (where the coordinate parametrizing the conformal manifold is $t$), and choosing basis of operators with diagonal structure constants and orthogonal metric $g_{ij} = g_1 \delta_{ij}$, the above equation further simplifies to:

\[ \partial_t \partial_t \log g_k = \frac{g_{k+1}}{g_k} - \frac{g_k}{g_{k-1}} - g_1 , \quad k \in \{1, \cdots, \dim R - 1\}, \quad g_{\dim R} = 0 , \quad (4.28) \]

where $R$ is the BPS ring of interest, for example, $\dim R_{tc} = 4$ for the twisted chiral ring of the Quintic. The above equation is known as the Toda equation in the literature, which is usually written (after defining $q_k := \log g_k + Z_{g2}$) in the more familiar form:

\[ \partial_t \partial_t q_k = e^{q_{k+1}-q_k} - e^{q_k-q_{k-1}} , \quad k \in \{1, \cdots, \dim R - 1\}, \quad q_{\dim R} = -\infty , \quad (4.29) \]

The condition $q_{\dim R} = -\infty$ signifies that the above equations are the equations of motion of a finite non-periodic Toda chain consisting of $\dim R$ sites located at $q_0, \cdots, q_{\dim R - 1}$ where $q_k$ and is bound to $q_{k+1}$ by the potential $e^{q_{k+1}-q_k}$.

The $tt^*$ equations (4.26) are known to be integrable. In particular, the Toda equation (4.28) can be solved explicitly given $g_1$ which we can compute using localization.

---

31 The commutator of structure constants in (4.26b) looks like: $[C_\mu, \overline{C}_\nu] j_i = C_{kj} g_{kl} \overline{C}^l_{\nu m} g_{mj} j_i$.  
32 i.e., they are indices for the exactly marginal couplings.  
33 For details see [27] where the underlying theory was four dimensional but this portion of the computation applies to 2D as well.  
34 Such as the basis $\{\sigma^i\}_{i=0}^3$ for the twisted chiral ring of the Quintic.
Note that the Toda equation for the norms of the operators in an orthogonal basis with diagonal structure constant, in a one parameter theory, can be derived simply from the expression of these norms as a ratio of determinants (such as (4.22)). An explicit derivation was presented in [4] in the context of 4d \( \mathcal{N} = 2 \) SCFT with SU(2) gauge group, the proof remains unchanged for one parameter 2d BPS rings.

### 4.2 Chiral Rings of the LG Minimal Models

These are theories of chiral multiplets \( X_i \), and the theories are characterized by a superpotential \( W(X_i) \) and a Kähler potential \( K(X_i, \bar{X}_i) \). If the superpotential has a quasi-homogenous singularity

\[
W(\lambda^m X_i) = \lambda^2 W(X_i)
\]

the Landau-Ginzburg model flows in the IR to a \( (2, 2) \) SCFT. The universality class of the SCFT is insensitive to the choice of Kähler potential, which henceforth we take to be canonical: \( K(X, \bar{X}) = \frac{1}{2} \delta_{ij} X_i \bar{X}_j \).

The equations of motion of the Landau-Ginzburg model gives:

\[
\partial_i W \propto D^2 \bar{X}_i.
\]

Thus the bottom component of \( \partial_i W \) is not only \( \overline{Q}_B \)-closed, but also \( \overline{Q}_B \)-exact. Therefore the chiral operator (the bottom component of) \( \partial_i W \) is represented by 0 in correlation functions with other chiral operators (\( \partial_i W \) is not represented by 0 in an arbitrary correlator). Therefore the chiral ring of the SCFT is the quotient

\[
\mathcal{R}^c = C[X_1, \ldots, X_n]/\langle dW \rangle.
\]

The chiral ring is spanned by polynomials in the fields subject to the relations \( dW = 0 \). Unorbifolded Landau-Ginzburg models have a trivial twisted chiral ring. We will recover the result (4.32) from the sphere partition function in what follows.

The \( (2, 2) \) unitary minimal models admit a Landau-Ginzburg description. The minimal model modular invariants pertain to an ADE classification. This is mirrored by the following ADE family of Landau-Ginzburg models:

\[
\begin{align*}
A_k : & \quad W = X^{k+1} \\
D_k : & \quad W = X^{k-1} + XY^2 \\
E_6 : & \quad W = X^3 + Y^4 \\
E_7 : & \quad W = X^3 + XY^3 \\
E_8 : & \quad W = X^3 + Y^5
\end{align*}
\]

The associated minimal models have the following properties:

- Central charge \( c = 3 - \frac{6}{h} \), where \( h \) is the Coxeter number of the corresponding Lie group \( G \).
• Dimension of the chiral ring, \( \dim(\mathcal{R}_G^c) = \text{rank}(G) \).

• The chiral operators \( \mathcal{O}_i \in \mathcal{R}_G^c \) have dimension \( \Delta_i = d_i - 2 \), where \( d_i \) is the order of the \( i \)-th Casimir of \( G \).

Since \( d_i \leq h \), all operators in the minimal models are relevant.

Extremal correlators of chiral and anti-chiral operators in a Landau-Ginzburg model on \( S^2 \) with a superpotential \( W(X_i) \) are given by [7] (we set the radius of the sphere to 1)

\[
\left\langle \mathcal{O}_i(N)\overline{\mathcal{O}}_j(S) \right\rangle_{S^2} = \int dX_1 dX \mathcal{O}_i(X) \overline{\mathcal{O}}_j(X) e^{-4\pi i (W(X)+\overline{W}(X))}.
\]

(4.34)

Recall from the general discussion of §3.1 that these are precisely the correlators that can be computed in background-B by localizing the path integral with respect to the supercharge \( Q_B \).

\( A_{k+1} \) minimal model

We start first by analyzing the Landau-Ginzburg representation of the \( A_{k+1} \) minimal model. The \( su(2|1)_B \)-invariant \( S^2 \) partition function for this Landau-Ginzburg minimal model is given by

\[
Z^{A_{k+1}}_{S^2} = \int dX d\overline{X} e^{-4\pi i W(X) - 4\pi i \overline{W}(\overline{X})}
\]

\[
= \int dX dY e^{-4\pi i (x+iy)^{k+1} - 4\pi i (x-iy)^{k+1}}
\]

\[
= \int_0^{2\pi} d\theta \int_0^{\infty} dr r e^{-8\pi i r^{k+2} \cos((k+2)\theta)} = \frac{\pi}{k+2} \frac{\Gamma\left(\frac{1}{k+2}\right)}{\Gamma\left(\frac{k+1}{k+2}\right)}.
\]

(4.35)

We would like to observe that this matches exactly with the \( su(2|1)_A \)-invariant \( S^2 \) partition function of the same Landau-Ginzburg model. In this theory, the \( U(1)_V \)-charge of \( X \) is fixed by the superpotential to be \( \frac{2}{k+2} \), and it follows from the formulae in [9, 6] that the \( su(2|1)_A \)-invariant partition function is indeed (4.35). The physical interpretation of this equality of partition functions is mirror symmetry for the \( k \)-th minimal model \( \text{MM}_k \), which exchanges

\[
\text{MM}_k \leftrightarrow \frac{\text{MM}_k}{Z_k}.
\]

(4.36)

The ring relation \( X^{k+1} = 0 \) can be derived from the \( S^2 \) partition function. Indeed, using the identity

\[
\int dX d\overline{X} d\frac{d}{dX} e^{-4\pi i (X^{k+2} + \overline{X}^{k+2} + i \overline{X})} = 0,
\]

(4.37)

from which it follows that

\[
\left\langle X^{k+1}(N)\overline{X}^{\ell}(S) \right\rangle = 0 \quad \forall \ell,
\]

(4.38)
implying that
\[ X^{k+1} = 0. \] (4.39)

This can be obtained from a differential equation. First we deform the supertotential by adding a source for the generator of the ring \( W = X^{k+2} + tX \). The two-sphere partition function then obeys
\[ \partial_t^{k+1} Z_{S^2}^{A^{k+1}}|_{t=0} = 0 \]
\[ \partial_{t}^{k+1} Z_{S^2}^{A^{k+1}}|_{t=0} = 0. \] (4.40)

The two-point functions of chiral operators are given by (we do the computation in using Riemann bilinear identity):
\[ M_{m,n}^{A_{k+1}} := \langle X^{m}(N)X^{n}(S) \rangle_{S^2} \]
\[ = \frac{1}{Z_{S^2}} \int_{\mathbb{C}} dX d\overline{X} X^{m} \overline{X}^{n} e^{-4\pi i W(X)-4\pi i \overline{W}(\overline{X})} \]
\[ = \begin{cases} \frac{\pi (-i)^{q}}{(k+2)^{2} S^2} (4\pi) - \frac{2(k+1)}{k+2} q \Gamma \left( \frac{k+1+q}{k+2} \right) \Gamma \left( \frac{k+1}{k+2} \right) & \text{if } q := \frac{n-m}{k+2} \in \mathbb{Z} \\ 0 & \text{otherwise} \end{cases} \] (4.41a)

(4.41b)

We see that any two operators with integer dimensions can mix. Recall that, \( \Gamma(-s) \) has poles at \( s \in \mathbb{N}_{\geq 0} \). Therefore (4.41b) implies:
\[ M_{m,n}^{A_{k+1}} = 0 \quad \text{for} \quad \frac{k-m+1}{k+2} = -s \Rightarrow m = k+1+s(k+2) \quad \text{where} \quad s \in \mathbb{N}_{\geq 0}. \] (4.42)

This in particular shows that, for \( q = s = 0 \), \( M_{k+1,k+1}^{A_{k+1}} = 0 \). Now, let us denote by \( M_{(n)}^{A_{k+1}} \) the matrix \( M_{i,j}^{A_{k+1}} \) with \( i,j = 0, \cdots, n \). Then \( M_{(k+1)}^{A_{k+1}} \) is a diagonal matrix with exactly one zero row (the \((k+2)\)'th row). This implies, using the Gram-Schmidt procedure (c.f. (3.28)):
\[ \left\langle X^{k+1}(0)X^{k+1}(\infty) \right\rangle_{\mathbb{C}^{2}} = 4^{k+2} \frac{\det M_{(k+1)}^{A_{k+1}}}{\det M_{(k)}^{A_{k+1}}} = 0 \] (4.43)

By the Reeh-Schlieder theorem, we arrive at the ring relation
\[ X^{k+1} = 0 \] (4.44)

This implies that the chiral ring is given by:
\[ \mathcal{R}_{k+1}^{A} = \mathbb{C}[X]/\langle X^{k+1} \rangle. \] (4.45)

\[ \text{In this particular case it is actually unnecessary to use the Gram-Schmidt procedure, because the operator } X^{k+1} \text{ has dimension } \frac{k+1}{k+2} < 1 \text{ and the operators } 1, X, \cdots, X^{k+1} \text{ do not mix with each other (mixing can occur only at integer gaps in dimensions).} \]
It can also be explicitly checked that \( \langle X^m(0)X^m(\infty) \rangle_{\mathbb{R}^2} = 0 \) for all \( m > k \) implying that
\[
X^m = 0 \quad m > k.
\]
This can be shown as follows. (4.41b) allows to write a recursion relation between \( M_{m,k+2}^{A_{k+1}} \) and \( M_{m,k+2,n}^{A_{k+1}} \). Note that if we shift \( m \to m + k + 2 \) then \( m - n + q(k + 2) = 0 \) can be maintained by simultaneously shifting \( q \to q - 1 \). Therefore,
\[
M_{m,k+2,n}^{A_{k+1}} = \frac{\pi (-i)^{q-1}}{(k + 2)Z_{\mathbb{R}^2}} (\mp)^{-q+1} \frac{\Gamma (\frac{m+1}{k+2} + q)}{\Gamma (\frac{k-m+1}{k+2} - 1)}
\]
(4.47)
This implies that for any \( m > k + 1 \) the \((m+1)\)'th row of \( M_{(m)}^{A_{k+1}} \) is a multiple of the \((m - k - 1)\)'th row of \( M_{(m)}^{A_{k+1}} \). Therefore, for \( m > k \), the number of 0 eigenvalues of \( M_{(m)}^{A_{k+1}} \) is \( m - k \) (note that \( M_{(k+1)}^{A_{k+1}} \) already has one zero eigenvalue). Hence:
\[
\langle X^m(0)X^m(\infty) \rangle_{\mathbb{R}^2} = 2 \pi \frac{\det M_{(m-1)}^{A_{k+1}}}{\det M_{(m)}^{A_{k+1}}} \sim \frac{0^{m-k}}{0^{m-k-1}} = 0, \quad \text{for} \quad m > k.
\]
(4.48)

Finally, we can make contact with previously known results about the OPE structure of these chiral primaries obtained from CFT methods [28, 29]. First, let us normalize the chiral ring operators by defining \( \hat{X}^n := \frac{X^n}{\|X^n\|} \) where \( \|X^n\|^2 = \langle X^m(0)X^m(\infty) \rangle_{\mathbb{R}^2} \). Then using the relation \( X^mX^n = X^{m+n} \) we can compute the OPE coefficients for the normalized operators:
\[
\hat{X}^m\hat{X}^n = F_{m,n}^{A_{k+1}} \hat{X}^{m+n}, \quad F_{m,n}^{A_{k+1}} = \frac{\|X^{m+n}\|}{\|X^m\||X^n\|}.
\]
(4.49)
These OPE coefficients depend only on the dimensions of the operators and the central charge \( c \) [28, 29]. For the ADE models, the central charge \( c = 3 - \frac{6}{h} \) where \( h \) is the Coxeter number of the corresponding Lie group. For example, the Coxeter number of \( A_{k+1} \) is \( k + 2 \), so the central charge of the \( A_{k+1} \) model is:
\[
c_{A_{k+1}} = \frac{3k}{k + 2}.
\]
(4.50)
The central charge dependence of the OPE coefficients is implicit in (4.49) and can be seen through the dependence of the correlation functions on \( k \) (see (4.41b)). These OPE coefficients can be computed using (4.49), (4.41b), and (3.28), the result is:
\[
F_{m,n}^{A_{k+1}} = \left[ \frac{\Gamma (\frac{1}{k+2}) \Gamma (\frac{k-m+1}{k+2}) \Gamma (\frac{k-n+1}{k+2}) \Gamma (\frac{m+n+1}{k+2})}{\Gamma (\frac{k+1}{k+2}) \Gamma (\frac{m+1}{k+2}) \Gamma (\frac{n+1}{k+2}) \Gamma (\frac{k-m-n+1}{k+2})} \right]^{\frac{h}{3}}.
\]
(4.51)
These coefficients can also be read off from the results of [28, 29] and they match with our expression.
$D_{k+1}$ minimal model

The same analysis can be carried out for the $D_{k+1}$ minimal model in a completely analogous way. The superpotential for the LG theory describing this minimal model is:

$$W(X, Y) = X^k + XY^2, \quad (4.52)$$

with two generators $X$ and $Y$ corresponding to conformal primaries of dimensions $\frac{1}{k}$ and $\frac{k-1}{2k}$ respectively. With the canonical kinetic Lagrangian $\int d^4\theta (X \overline{X} + Y \overline{Y})$ the equations of motion tells us:

$$D^2X \propto kX^{k-1} + Y^2, \quad D^2Y \propto XY. \quad (4.53)$$

Therefore, the chiral ring can be described as:

$$\mathcal{R}^c_{D_{k+1}} = \mathbb{C}[X, Y]/\langle kX^{k-1} + Y^2, XY \rangle. \quad (4.54)$$

We will derive these ring relations by computing correlation functions of the generators and showing that the operators $kX^{k-1} + Y^2$ and $XY$ are zero in the chiral ring. Note that according to the relations, a minimal (dimension-wise) basis for the ring is given by:

$$1, X, \ldots, X^{k-1}, \quad \text{and} \quad Y. \quad (4.55)$$

Here $X^{k-1}$ has the highest dimension, $\frac{k-1}{k} < 1$. Based on our supergravity analysis we can expect that operators can only mix at integer gaps in dimensions; in fact we will establish this by explicit computation. This implies that there is no mixing among the operators in the minimal basis, simplifying our computations.

When put on a two-sphere, a general extremal correlation function in this LG model is given by:

$$M^{D_{k+1}}_{m,n,p,q} := \langle X^m(N)Y^n(N)\overline{X}^p(S)\overline{Y}^q(S) \rangle_{S^2}$$

$$= \frac{1}{Z_{S^2}^{D_{k+1}}} \int_{S^2} dX d\overline{X} dY d\overline{Y} X^m Y^n \overline{X}^p \overline{Y}^q e^{-4\pi i (kX^{k-1} + Y^2 + \overline{X}^{k-1} + \overline{Y}^2)} \quad (4.56)$$

We can carry out the $Y, \overline{Y}$ integrals first:

$$\int_{\mathbb{C}} d\overline{Y} Y^n \overline{Y}^q e^{-4\pi i (XY^2 + \overline{X}Y^2)} = X^{-n+1} \overline{X}^{-\frac{n+1}{2}} \int_{\mathbb{C}} d\overline{Y} Y^n \overline{Y}^q e^{-4\pi i (Y^2 + \overline{Y}^2)}$$

$$= X^{-n+1} \overline{X}^{-\frac{n+1}{2}} Z_{S^2}^{A_{1}} M^{A_{1}}_{n,q}. \quad \text{[c.f. (4.41a)]} \quad (4.57)$$

Then we can perform the integrals over $X, \overline{X}$, which leads to an expression for the $D$-type extremal correlators in terms of the $A$-type extremal correlators:

$$M^{D_{k+1}}_{m,n,p,q} = \frac{Z_{S^2}^{A_{1}} Z_{S^2}^{A_{k-1}}}{Z_{S^2}^{D_{k+1}}} M_{n,q}^{A_{1}} M_{m-\frac{n+1}{2}, p-\frac{n+1}{2}}^{A_{k-1}}. \quad (4.58)$$

$^{36}$As we found explicitly for the $A_{k+1}$ model following (4.41b).
Let us define some symbols:
\[
\tilde{m} := m - \frac{n + 1}{2}, \quad \tilde{p} := p - \frac{q + 1}{2}, \quad v := \frac{q - n}{2}, \quad \chi := \frac{\tilde{p} - \tilde{m}}{k},
\]
then we can write (4.58) more explicitly as (c.f. (4.41b)):
\[
M_{m,n,p,q}^{D_{k+1}} = \begin{cases} 
1 & \quad \text{if } v, \chi \in \mathbb{Z} \\
\left(\frac{-i}{2}\right)^{v} (4\pi)^{1-n-v-\chi} (\pi)^{2k} (\pi)^{1-n-\chi} \Gamma\left(\frac{1+n+v}{2}\right) \Gamma\left(\frac{1+\tilde{m}+v}{2}\right) \Gamma\left(\frac{1+\tilde{p}+\chi}{2}\right) \Gamma\left(\frac{1+\tilde{m}+\chi}{2}\right) & \quad \text{otherwise}
\end{cases}
\]
(4.60)

Noting the difference in dimension:
\[
\Delta(X^mY^n) - \Delta(X^pY^q) = v + \chi, \quad (4.61)
\]
we observe that mixing between different operators can occur on the sphere only if their dimensions differ by an integer amount. Since all the operators in the minimal basis (4.55) have dimensions less than 1, there is no mixing among them. Therefore, their correlation functions on the sphere of unit radius, namely the ones given by (4.60), are simply proportional to the corresponding flat space correlators.

In order to check the ring relations, we define the following two operators:
\[
O_1 := kX^{k-1} + Y^2, \quad \text{and} \quad O_2 := XY. \quad (4.62)
\]

Using the explicit form of the correlation functions (4.60), we can easily check that these two operators have zero norms:
\[
\|O_1\|^2 = \langle O_1(0)\overline{O}_1(\infty)\rangle_{S^2} = 4^k \left\langle O_1(N)\overline{O}_1(S)\right\rangle_{S^2} = 4^k \left(2M_{k-1,0,0,0}^{D_{k+1}} + kM_{k-1,0,0,2}^{D_{k+1}} + kM_{0,2,k-1,0}^{D_{k+1}} + M_{0,2,0,2}^{D_{k+1}}\right) = 0, \quad (4.63)
\]
and similarly,
\[
\|O_2\|^2 = \langle O_2(0)\overline{O}_2(\infty)\rangle_{S^2} = 2^k \left\langle O_2(N)\overline{O}_2(S)\right\rangle_{S^2} = 2^k M_{1,1,1,1}^{D_{k+1}} = 0. \quad (4.64)
\]
By the Reeh-Schlieder theorem, we arrive at the ring relations:
\[
kX^{k-1} + Y^2 = XY = 0, \quad (4.65)
\]
giving us the chiral ring (4.54).

Once we normalize the chiral primaries, \(\tilde{X}^mY^n := \frac{X^mY^n}{\|X^mY^n\|}\), we can compute the OPE coefficients for the product of two arbitrary chiral primaries in terms of the extremal correlators (as we did for the \(A\) series in (4.49) and (4.51)).

Let us make a few remarks about the computation. We define the OPE coefficients of the normalized operators by the following equation:
\[
\tilde{X}^mY^n \tilde{X}^pY^q = \mathcal{F}^{D_{k+1}}_{(m,n),(p,q)} \tilde{X}^{m+n}Y^{p+q}, \quad \mathcal{F}^{D_{k+1}}_{(m,n),(p,q)} = \frac{\|X^{m+n}Y^{p+q}\|}{\|X^mY^n\| \|X^pY^q\|}. \quad (4.66)
\]
As we mentioned after (4.49), these coefficients depend only the dimensions of the operators and the central charge, in particular, they should be computable without making a choice a modular invariant. Therefore we should expect the OPE coefficients defined in (4.49) and the ones in (4.66) to be the same:

$$F_{m,n}^{A_k+1} = F_{(p,q),(r,s)}^{D_{k'+1}}$$,

(4.67)

whenever the central charges of the two theories and the dimensions of the involved operators coincide, i.e.

$$c_{A_{k+1}} = c_{D_{k'+1}} \Rightarrow k' = \frac{k + 2}{2},$$  

(4.68a)

$$\Delta_{A_{k+1}}(X^m) = \Delta_{D_{k'+1}}(X^p Y^q) \Rightarrow m = \frac{1}{2}(4p + kq),$$  

(4.68b)

$$\Delta_{A_{k+1}}(X^n) = \Delta_{D_{k'+1}}(X^r Y^s), \quad n = \frac{1}{2}(4r + ks).$$  

(4.68c)

Explicit computation shows that the equality (4.67) indeed holds given that the above conditions are satisfied.

**Exceptional minimal models**

Our discussion so far for the $A$ and the $D$-series of minimal models readily extends to the $E_6$, $E_7$ and $E_8$ models. Like the $D$-series, the chiral rings of these models have two generators. The $E_6$ and the $E_8$ minimal model superpotentials, namely $X^3 + Y^4$ and $X^3 + Y^5$ (4.33), are decoupled sums of two polynomials in these two generators and therefore the chiral rings of these two models are simply Cartesian products of two $A$-type chiral rings:

$$\mathcal{R}_{c,E_6}^c = \mathcal{R}_{c,A_2}^c \times \mathcal{R}_{c,A_3}^c, \quad \mathcal{R}_{c,E_8}^c = \mathcal{R}_{c,A_2}^c \times \mathcal{R}_{c,A_4}^c.$$  

(4.69)

The $E_7$ model involves nontrivial coupling between the two generators analogous to the $D$-series. Recall that the $E_7$ superpotential is $X^3 + XY^3$ and therefore the chiral ring is:

$$\mathcal{R}_{c,E_7}^c = \mathbb{C}[X,Y]/(3X^2 + Y^3, XY^2).$$  

(4.70)

There are two chiral primaries $X$ and $Y$ of dimensions $\frac{1}{2}$ and $\frac{3}{2}$ respectively. A basis for the chiral ring is given by $\{1, Y, X, Y^2, XY, Y^3, X^2 Y\}$ in increasing order of dimension. The highest dimensional chiral primary $X^2 Y$ has dimension $\frac{5}{2} < 1$ and therefore there is no mixing among these basis operators when we put the corresponding LG theory on a sphere. Thus once again we have proportionality between extremal correlators on a sphere of unit radius and extremal correlators on $\mathbb{R}^2$. Just as we did in (4.58), we

---

[37] The Coxeter numbers of $A_{k+1}$ and $D_{k+1}$ are $(k + 2)$ and $2k$ respectively. Two ADE models have the same central charge as long as the corresponding Lie groups have the same Coxeter number.
can write down the extremal correlators in this model in terms of \( A \)-series extremal correlators:

\[
M_{m,n,p,q}^{E_7} := \langle X^m(N)Y^n(N)\bar{X}^p(S)\bar{Y}^q(S) \rangle_{S^2} = \frac{Z_{S^2}^{A_2} Z_{S^2}^{A_2}}{Z_{S^2}^{E_7}} M_{m,n}^{A_2} M_{p,q}^{A_2} m^{-1/2} p^{-1/2} n^{-1/2} \quad (4.71)
\]

Using the explicit form of the \( A \)-type extremal correlators (4.41b), we can verify that in the \( E_7 \) model the operators \( O_1 := 3X^2 + Y^3 \), \( O_2 := XY^2 \) have zero norms:

\[
\|O_1\|^2 = 2^{4/3} \left( 9M_{2,0,2,0}^{E_7} + 3M_{2,0,0,3}^{E_7} + 3M_{0,3,2,0}^{E_7} + M_{0,3,0,3}^{E_7} \right) = 0,
\]

\[
\|O_2\|^2 = 2^{14/3} M_{1,2,1,2}^{E_7} = 0.
\]

This establishes the ring relations in (4.70) by identifying \( O_1 \) and \( O_2 \) with the null operator.

5 Epilogue

In this paper we have approached the computation of 2D BPS ring structure constants from the conceptually straightforward way of computing the relevant correlation functions. The main tool at our disposal was supersymmetric localization allowing exact computation of these correlation functions on the sphere. The main obstacle in using these results to compute the ring structure is the presence of conformal anomalies on the sphere leading to operator mixing. We have explored the roots of this mixing in the supergravitational descriptions of the sphere, and we have outlined a way of computing the flat space correlators from the sphere partition function in the presence of such mixing. We have demonstrated our method in some familiar theories of interest and reproduced known results about the structure constants that were previously obtained via CFT methods and we have also verified all the ring relations. This work builds on previous works in 4D and extends the applicability and usefulness of the already exceptionally useful results from localization while providing a simple elementary perspective on the BPS algebraic structures of 2D \( \mathcal{N} = (2,2) \) theories.

Acknowledgment

We thank Jaume Gomis for motivating and providing core insights behind this project, as well as for many essential discussions on the subject.

A The \( \mathcal{N} = (2,2) \) superconformal Algebra

We use complex coordinates on \( \mathbb{R}^2 \):

\[
z = x + iy, \quad \bar{z} = x - iy.
\]
The $\mathcal{N} = (2, 2)$ superconformal algebra $^{38}su(2|2)$ contains eight supercharges:

$$Q_+, Q_-, \bar{Q}_+, \bar{Q}_-,$$ and, $$S_+, S_-, \bar{S}_+, \bar{S}_-,$$ (A.2)

and the following bosonic generators:

Rotation in $\mathbb{R}^2$, $u(1)_L$ :
$$2(\bar{L}_0 - L_0) =: 2J_L$$
Dilatation :
$$L_0 + \bar{L}_0 =: \Delta$$
Translations :
$$L_{-1}, \bar{L}_{-1}$$
Special conformal transformations :
$$L_1, \bar{L}_1$$
Vector R-symmetry, $u(1)_V$ :
$$J_V$$
Axial R-symmetry, $u(1)_A$ :
$$J_A$$

where $L_s := -z^s \partial_z$ and $\bar{L}_s := -\bar{z}^s \partial_{\bar{z}}$ generate the conformal algebra $\text{conf}(\mathbb{R}^2) = so(3, 1)$:

$$[L_r, L_s] = (r - s)L_{r+s}, \quad [\bar{L}_r, \bar{L}_s] = (r - s)\bar{L}_{r+s}, \quad r, s \in \{-1, 0, 1\}$$ (A.4)

The nonzero anti-commutation relations of the supercharges (A.2) are:

$$\{Q_+, Q_+\} = 2L_0 + \frac{1}{2}(J_V + J_A),$$
$$\{Q_-, Q_-\} = 2\bar{L}_0 + \frac{1}{2}(J_V - J_A),$$
$$\{\bar{Q}_+, S_+\} = 2\bar{L}_0 - \frac{1}{2}(J_V + J_A),$$
$$\{\bar{Q}_-, S_-\} = 2\bar{L}_0 - \frac{1}{2}(J_V - J_A).$$ (A.5c)

The commutators of the supercharges with the $u(1)$’s and the dilatation are conveniently expressed by specifying the charges of the supercharges under the respective generators:

$$| \begin{array}{c|cccc} & Q_+ & \bar{Q}_+ & S_+ & \bar{S}_+ \\ \hline 2J_L & \mp & \mp & \pm & \pm \\ J_V & - & + & - & + \\ J_A & \mp & \mp & \pm & \pm \\ 2\Delta & + & + & + & - \end{array}$$ (A.6)

The rest of the nonzero commutators of $su(2|2)$ are:

$$[L_1, Q_+] = S_+, \quad [L_1, \bar{Q}_+] = \bar{S}_+,$$  
$$[L_{-1}, S_+] = -Q_+, \quad [L_{-1}, \bar{S}_+] = -\bar{Q}_+, \quad [\bar{L}_1, Q_-] = S_-, \quad [\bar{L}_1, \bar{Q}_-] = \bar{S}_-, \quad [\bar{L}_{-1}, S_-] = -\bar{Q}_-, \quad [\bar{L}_{-1}, \bar{S}_-] = -Q_-. \quad (A.7)$$

$^{38}$We are only concerned with algebra that is globally defined on $\mathbb{R}^2$, i.e., the globally defined subalgebra of the super Virasoro algebra.
B Supersymmetry on the sphere

A theory with $\mathcal{N} = (2, 2)$ superconformal symmetry, namely the symmetry algebra $su(2|2)$, can be put on the two-sphere by a Weyl transformation, classically preserving the full superconformal symmetry. Though UV regularization will break the $su(2|2)$ symmetry to an $su(2|1)$ subalgebra. On the other hand, a nonconformal theory, such as a gauge theory, can preserve even classically only an $su(2|1)$ subalgebra of the full $su(2|2)$ superconformal algebra.

$su(2|1)$ subalgebras of $su(2|2)$ consist of the isometries of the two-sphere, supercharges that generate these isometries and a $u(1)$ subalgebra of the $u(1)_V \times u(1)_A$ R-symmetry algebra of $su(2|2)$. There are two non-equivalent $su(2|1)$ subalgebras of $su(2|2)$, one of them contains the vector R-symmetry $u(1)_V$ and the other one contains the axial R-symmetry $u(1)_A$. They are referred to as $su(2|1)_A$ and $su(2|1)_B$ respectively.

The two supersymmetric sphere backgrounds can be derived as two different supergravity backgrounds preserving four supercharges. We will refer to the $su(2|1)_A$ and $su(2|1)_B$ preserving sphere backgrounds as “background-A” and “background-B” respectively. The conformal Killing spinor equations are:

\[
\nabla_m \epsilon(x) = \eta(x), \quad \nabla_m \bar{\epsilon}(x) = \bar{\eta}(x),
\]

(B.1)

where $\epsilon, \bar{\epsilon}, \eta$ and $\bar{\eta}$, parametrize the $\overline{Q}, Q, \overline{S},$ and $S$ transformations. The two sphere backgrounds are defined by imposing constraints on the $S$-supersymmetries as we discuss in the following.

Background-A

The Killing spinor equation of the supersymmetric $S^2$ background preserving the vector R-symmetry is found by imposing on $\eta$ and $\bar{\eta}$ the following constraints [15, 9, 12, 20]:

\[
\eta = \frac{i}{2r} \epsilon, \quad \bar{\eta} = \frac{i}{2r} \bar{\epsilon}.
\]

(B.2)

So that the Killing spinor equations end up being:

\[
\nabla_m \epsilon(x) = \frac{i}{2r} \gamma_m \epsilon(x), \quad \nabla_m \bar{\epsilon}(x) = \frac{i}{2r} \gamma_m \bar{\epsilon}(x),
\]

(B.3)

where $r$ is the radius of the sphere, and the covariant derivative $\nabla_m$ does not contain any background field other than the spin connection. The Killing spinor equations

\[39\text{If the theory is to flow to a nontrivial CFT in the IR the theory must preserve both of the } U(1) \text{ R-symmetries.}
\]

\[40\text{Not related by any inner automorphism of } su(2|2).
\]

\[41\text{Note the slightly unfortunate notation that } u(1)_A \text{ is contained in } su(2|1)_B \text{ and not in } su(2|1)_A.
\]
have a (complex) four dimensional space of solutions that can be written as
\[ \epsilon_{A}^{B} \tilde{\chi}_{0} \chi_{0}(x) = \frac{1}{\sqrt{1 + \frac{x^2}{4r^2}}} \left( 1 + i \frac{r}{2} x^m \Gamma_m \right) \chi_0, \quad (B.4a) \]
\[ \tilde{\epsilon}_{A}^{B} \chi_{0} \tilde{\chi}_{0}(x) = \frac{1}{\sqrt{1 + \frac{x^2}{4r^2}}} \left( 1 + i \frac{r}{2} x^m \Gamma_m \right) \tilde{\chi}_0. \quad (B.4b) \]

Here \( \chi_0 \) and \( \tilde{\chi}_0 \) are two constant Dirac spinors parametrizing the space of solutions.

### Background-B

Analogously, the axial R-symmetry preserving background is defined by imposing in the conformal Killing spinor equation\(^{[B.1]} \)\(^{[B.5]} \):
\[ \eta = \frac{i}{2r} \tilde{\epsilon}, \quad \tilde{\eta} = \frac{i}{2r} \epsilon, \quad (B.5) \]
so that we have the following Killing spinor equations:
\[ \nabla_m \epsilon(x) = \frac{i}{2r} \gamma_m \tilde{\epsilon}(x) \quad \nabla_m \tilde{\epsilon}(x) = \frac{i}{2r} \gamma_m \epsilon(x). \quad (B.6) \]
These can be solved by defining:
\[ \epsilon := \epsilon_+ + \tilde{\epsilon}_-, \quad \tilde{\epsilon} := \epsilon_- + \tilde{\epsilon}_+ \quad (B.7) \]
which satisfy the already solved equations\(^{[B.3]} \):
\[ \nabla_m \epsilon = \frac{i}{2r} \gamma_m \epsilon \quad \nabla_m \tilde{\epsilon} = \frac{i}{2r} \gamma_m \tilde{\epsilon}. \quad (B.8) \]
Thus we find that the solutions to\(^{[B.6]} \) are given by:
\[ \epsilon_{B}^{A} \chi_0 \tilde{\chi}_0(x) = \frac{1}{\sqrt{1 + \frac{x^2}{4r^2}}} \left( \chi_{0+} + \tilde{\chi}_{0-} + i \frac{r}{2} x^m \Gamma_m (\chi_{0-} + \tilde{\chi}_{0+}) \right), \quad (B.9a) \]
\[ \tilde{\epsilon}_{B}^{A} \tilde{\chi}_0 \chi_0(x) = \frac{1}{\sqrt{1 + \frac{x^2}{4r^2}}} \left( \chi_{0-} + \tilde{\chi}_{0+} + i \frac{r}{2} x^m \Gamma_m (\chi_{0+} + \tilde{\chi}_{0-}) \right), \quad (B.9b) \]
parametrized by two constant Dirac spinors \( \chi_0 \) and \( \tilde{\chi}_0 \).

### C  Ward identity

Let us present the proof of the Ward identity from\(^{[3.1]} \) for twisted chiral multiplets in background-A.

\(^{[B.3]} \) We are using \( \gamma \) and \( \Gamma \) to refer to the curved space and flat space gamma matrices respectively. In stereographic coordinate the metric on the sphere of radius \( r \) is \( \left( 1 + \frac{x^2}{4r^2} \right)^{-2} \text{diag}(1, 1). \)
Supersymmetric deformations of the action

For a twisted chiral primary $Y$ of Weyl weight $w$, the $su(2|1)_A$ variations of the twisted chiral multiplet $\Psi = (Y, \zeta, G)$, generated by the Killing spinors $\epsilon$ and $\tilde{\epsilon}$, are \footnote{15}:

\begin{align}
\delta Y &= \tilde{\epsilon}_+ \zeta_+ - \epsilon_- \zeta_+, \quad \text{(C.1a)} \\
\delta \zeta_+ &= -i \partial Y \tilde{\epsilon}_+ + \left( G + \frac{w}{r} Y \right) \tilde{\epsilon}_+, \quad \text{(C.1b)} \\
\delta \zeta_- &= i \partial Y \epsilon_+ - \left( G + \frac{w}{r} Y \right) \epsilon_-, \quad \text{(C.1c)} \\
\delta G &= -i \tilde{\epsilon}_- \nabla \zeta_+ + i \epsilon_+ \nabla \zeta_- + \frac{w}{r} (\zeta_+ \epsilon_- - \zeta_- \tilde{\epsilon}_+) \quad \text{.} \quad \text{(C.1d)}
\end{align}

The twisted F-term action for $\Psi$ on the sphere invariant under these variations is given by \footnote{7, 12}:

\begin{align}
I^{tc-F}_w(\Psi) := \int_{S^2} d^2x \sqrt{g(x)} G(\Psi), \quad &G(\Psi) = G + \frac{w-1}{r} Y. \quad \text{(C.2)}
\end{align}

The subscript on $I$ refers to the Weyl weight of $Y$, the Weyl weight of the integral $I^{tc-F}_w$ is $w - 1$, therefore a deformation of an action $S$ by this term can be introduced by simply introducing a coupling $\tau$ of Weyl weight $(1 - w)$:

\begin{align}
S \rightarrow S - \frac{i \tau}{4\pi} I^{tc-F}_w(\Psi). \quad \text{(C.3)}
\end{align}

We want to show that the integrated operator $I^{tc-F}_w(\Psi)$ localizes to a point inside an extremal correlator. To proceed, let us pick a particular supercharge $Q_A \in su(2|1)_A$ by restricting $\tilde{\chi}_0$ in (B.4) to be chiral:

\begin{align}
\tilde{\chi}_{0+} = 0. \quad \text{(C.4)}
\end{align}

Then the Killing spinor (B.4b), which we write simply as $\tilde{\epsilon}$, becomes:

\begin{align}
\tilde{\epsilon}_+ = \frac{1}{\sqrt{1 + \frac{x^2}{4r^2}}} \frac{i}{2r} x^m \Gamma_m \tilde{\chi}_{0-}, \quad \tilde{\epsilon}_- = \frac{1}{\sqrt{1 + \frac{x^2}{4r^2}}} \tilde{\chi}_{0-}. \quad \text{(C.5)}
\end{align}

Solving (C.1b) for $G$ and substituting it in the expression for $G$ in (C.2), we find:

\begin{align}
G(\Psi) = \delta \left( \frac{\tilde{\epsilon}_+^\dagger \zeta_+}{||\tilde{\epsilon}_+||^2} \right) + \frac{i}{||\tilde{\epsilon}_+||^2} \tilde{\epsilon}_+^\dagger \overline{\nabla} (Y \tilde{\epsilon}_-). \quad \text{(C.6)}
\end{align}

were $||\tilde{\epsilon}_+||^2 := \tilde{\epsilon}_+^\dagger \tilde{\epsilon}_+$. Using complex coordinates $z = x^1 + i x^2$ and $\overline{z} = x^1 - i x^2$ (so that $\tilde{\epsilon}_+$ satisfies the simple equations $\nabla_z \tilde{\epsilon}_+ = 0$ and $\nabla_{\overline{z}} \tilde{z}_+^\dagger \frac{\tilde{\epsilon}_+^\dagger}{||\tilde{\epsilon}_+||^2} = 0$) we can turn the second term into a total derivative:

\begin{align}
G(\Psi) = \delta \left( \frac{\tilde{\epsilon}_+^\dagger \zeta_+}{||\tilde{\epsilon}_+||^2} \right) + 2i \nabla_z \left( \frac{1 + \frac{x^2}{4r^2}}{||\tilde{\epsilon}_+||^2} \tilde{\epsilon}_+^\dagger \Gamma_1 \tilde{\epsilon}_- Y \right). \quad \text{(C.7)}
\end{align}
The key point here is that the norm of $\tilde{\epsilon}_+$ vanishes at $z = \bar{z} = 0$ (see (C.5)) and therefore the space-time integral of the derivative localizes at the origin, which we call the North pole $N$. When inserted in a correlator with $Q_A$-closed operators, such as an extremal correlator, the $Q_A$-exact term in (C.7) can be ignored. In [15] the integral of the derivative was computed to be $-4\pi r Y(N)$. Therefore we reach the conclusion that inside an extremal correlator:

$$\left\langle \int_{S^2} d^2x \sqrt{g(x)} G(\Psi) \cdots \right\rangle_{S^2} = -4\pi r \langle Y(N) \cdots \rangle_{S^2} .$$

This is the equation (3.10). The equation (3.11) can be proven by starting from the $su(2|1)_A$-variation of a twisted anti-chiral multiplet. The analogous equations for the chiral and the anti-chiral multiplets in background-B are proven similarly.

D Contour integrals

On the two-sphere, the extremal correlation functions of chiral operators in a LG model of type $A_{k+1}$ involve the following integrals (c.f. [4.2]):

$$\int_{\mathbb{C}} dX d\bar{X} X^m \bar{X}^n e^{-4\pi i X^{k+2} - 4\pi i \bar{X}^{k+2}} = (4\pi)^{-\frac{2(m+1)}{k+2}} (-i)^q \int_{\mathbb{C}} dX d\bar{X} X^m \bar{X}^n e^{X^{k+2} - \bar{X}^{k+2}} ,$$

where $q = \frac{n-m}{k+2}$. After defining:

$$\omega_m := X^m e^{X^{k+2}} dX, \quad \tilde{\omega}_m := \bar{X}^m e^{-\bar{X}^{k+2}} d\bar{X} ,$$

we can write:

$$\int_{\mathbb{C}} dX d\bar{X} X^m \bar{X}^n e^{X^{k+2} - \bar{X}^{k+2}} = \frac{i}{2} \int_{\mathbb{C}} \omega_m \wedge \tilde{\omega}_n .$$

We will evaluate this integral by writing it as a sum of integrals of $\omega_m$ and $\tilde{\omega}_n$ over one-cycles that we will define momentarily. This procedure will use a generalization of the Riemann bilinear identity as explained in Appendix C of [30].

We denote by $\theta^\uparrow$ a ray originating from the origin of the complex plane and going off to infinity at an angle $\theta$ with the $x$-axis. And by $\mathcal{C}_{\theta_1, \theta_2}$ we will refer to a curve that originates at infinity, comes near the origin and then goes off to infinity again in a way such that it is wedged between the rays $\theta_1^\uparrow$ and $\theta_2^\uparrow$ and approaches these two rays.

43 The factor of $i/2$ is there because by $dX d\bar{X}$ we mean $dxdy = dx \wedge dy$ where $X = x + iy$ and $\bar{X} = x - iy$, whereas $dX \wedge d\bar{X} = (dx + idy) \wedge (dx - idy) = -2idy \wedge dy$.

44 The general idea behind evaluating certain integrals by decomposing them over some cycles comes from Picard–Lefschetz theory, which has been used in the past to compute integrals similar to ours [31, 32, 13]. Also note that the integration (D.1) seems to be computable using integral identity involving Bessel function of the first kind, but we were unable to confirm that all convergence conditions relevant for the integral identity are satisfied in the present case. Still, we note that a straightforward application of the Bessel function identity produces exactly the same result as the one given by the Riemann bilinear identity.
asymptotically. Such curves will be thought of as noncompact cycles in the complex plane. Our convention is such that $\theta_2^\uparrow$ follows $\theta_1^\uparrow$ in the anticlockwise direction in $C_{\theta_1, \theta_2}$. To denote the same contour with opposite orientation we will use the superscript “$-$”, e.g., $C_{\theta_1, \theta_2}$.

Figure: Some exemplary contours.

We define the following angles and cycles:

\[
\begin{align*}
\vartheta_a & := \pi \left( 2a - 1 \right) k + 2, \\
\varphi_a & := \frac{2\pi a}{k + 2}, \\
C_a & := C_{\vartheta_a, \vartheta_{a+1}}, \\
\tilde{C}_a & := C_{\varphi_a, \varphi_{a+1}}, \quad \text{for} \quad a \in \mathbb{Z},
\end{align*}
\]

(D.4)

In the figure below we draw a couple of these cycles and point out their intersection numbers. If two cycles $C_a$ and $\tilde{C}_b$ intersect at a point then we denote the intersection number of that point simply by $C \circ \tilde{C}$ when the point being referred to is understood.

Intersection numbers

- $C \circ \tilde{C} = 1$
- $C \circ \tilde{C} = -1$

Figure: The cycles $C$ and $\tilde{C}$.

Now we have:

\[
\begin{align*}
\oint_{C_a} \omega_m &= \frac{2\pi i a m + 1}{k + 2} \oint_{C_0} \omega_m, \\
\oint_{\tilde{C}_{-a-1}} \tilde{\omega}_n &= e^{-\frac{2\pi i a n + 1}{k + 2}} \oint_{\tilde{C}_{-1}} \tilde{\omega}_n,
\end{align*}
\]

(D.5)
which follows after redefining integration variables as $X \rightarrow X e^{\frac{2\pi ia}{k+2}}$ and $\bar{X} \rightarrow \bar{X} e^{-\frac{2\pi ia}{k+2}}$ respectively. Note that if we set $X = re^{i\vartheta_a}$ and $\bar{X} = re^{i\varphi_a}$ with $r > 0$ then we get the following asymptotic behaviours for the one forms:

$$r \rightarrow \infty : \quad \omega_m \sim r^{m} e^{i(m+1)\vartheta_a} e^{-r^{k+2}} \, dr, \quad \bar{\omega}_n \sim r^{n} e^{i(n+1)\varphi_a} e^{-r^{k+2}} \, dr,$$

making the integrals well defined. We now proceed to evaluate $\oint_{C_0} \omega_m$. We define a new variable:

$$Y := X^{k+2},$$

in terms of which we can write:

$$X = Y^{\frac{1}{k+2}}, \quad dX = \frac{1}{k+2} Y^{\frac{-k-1}{k+2}} dY.$$  \hfill (D.8)

and the angles defining the contour $C_0$ change as:

$$\vartheta_0 = -\frac{\pi}{k+2} \rightarrow -\pi, \quad \vartheta_1 = \frac{\pi}{k+2} \rightarrow \pi.$$  \hfill (D.9)

Since they represent the same direction in the complex plane we will write $\pi^\pm := \pi \pm \epsilon$ for the angles, where $\epsilon > 0$ is infinitesimal, to keep track of the orientation of the resulting contour. Therefore,

$$\oint_{C_0} \omega_m = \frac{1}{k+2} \oint_{C_+} Y^{\frac{-k+m+1}{k+2}} e^Y dY = \frac{1}{k+2} \frac{2\pi i}{\Gamma \left( \frac{k-m+1}{k+2} \right)}.$$  \hfill (D.10)

To get the last equality we used the integral form of the reciprocal Gamma function:

$$\frac{1}{\Gamma(z)} = \frac{1}{2\pi i} \oint_{C_{1+,-}} dt \, t^{-z} e^t.$$  \hfill (D.11)

Similarly by defining $\bar{Y} = -\bar{X}^{k+2}$ we find:

$$\oint_{\bar{C}_{-1}} \bar{\omega}_n = -\frac{e^{\frac{\pi i}{k+2} (n+1)}}{k+2} \oint_{C_{x+,x-}} Y^{-\frac{k-n+1}{k+2}} e^\bar{Y} d\bar{Y} = -2i \frac{e^{\frac{\pi i}{k+2} (n+1)}}{k+2} \sin \left( \frac{\pi (n+1)}{k+2} \right) \Gamma \left( \frac{n+1}{k+2} \right).$$  \hfill (D.12)

The last equality is a combination of (D.11) and Euler’s reflection formula:

$$\Gamma(1-z)\Gamma(z) = \frac{\pi}{\sin(\pi z)}.$$  \hfill (D.13)

The cycles defined in (D.4) are distinct for $a = 0, \cdots, k + 1$ and they satisfy:

$$\sum_{a=0}^{k+1} C_a = \sum_{a=0}^{k+1} \bar{C}_a = 0.$$  \hfill (D.14)

The cycles $\bar{C}_a$ are dual to the cycles $C_a$ with the intersection form:

$$I_{ab} := C_a \circ C_b = \delta_{a,b} - \delta_{a,b+1},$$  \hfill (D.15)
with inverse (restricting to $a, b = 1, \cdots, k + 1$ for independence):

\[
I_{ab}^{-1} = \begin{cases} 
1 & \text{when } a \geq b \\
0 & \text{otherwise} 
\end{cases}.
\] (D.16)

Complex conjugation acts on the contours as follows:

\[
\tilde{C}_a^* = C_{\varphi_a^*, \varphi_{a+1}^*} = C_{\varphi_{a+1}^*, \varphi_a} = C_{\varphi_{a-1}^*, \varphi_a} = \tilde{C}_{a-1}^*
\] (D.17)

Now, the generalization of Riemann bilinear identity [30] gives us:

\[
\int_{\mathbb{C}} \omega_m \wedge \tilde{\omega}_n = -\sum_{a, b = 1}^{k+1} I_{ab}^{-1} \oint_{C_a} \omega_m \oint_{\tilde{C}_b} \tilde{\omega}_n = -\sum_{a = 1}^{k+1} \sum_{b = 1}^{a} e^{\frac{2\pi i}{k+2} (m+1-a) - b(n+1)} \oint_{C_a} \omega_m \oint_{\tilde{C}_{b-1}} \tilde{\omega}_n,
\] (D.18)

The integrals are independent of $a$ and $b$, so we can evaluate the sum separately:

\[
\sum_{a = 1}^{k+1} \sum_{b = 1}^{a} e^{\frac{2\pi i}{k+2} (m+1-a) - b(n+1)} = e^{-\frac{2\pi i}{k+2} (n+1)} \left[ \sum_{a = 1}^{k+1} e^{\frac{2\pi i a}{k+2} (m+1)} - \sum_{a = 1}^{k+1} e^{\frac{2\pi i a}{k+2} (m-n)} \right]
\] (D.19)

Note that for $m + 1 \equiv 0 \pmod{(k + 2)}$ (D.10) vanishes since the Gamma function in the denominator acquires a pole, and therefore the expression (D.18) will vanish as well.

Assuming $m + 1 \not\equiv 0 \pmod{(k + 2)}$ we see that the first sum inside the parentheses in (D.19) is a sum over roots of unity excluding 1, therefore the first sum is $-1$. The second sum is also a sum over roots of unity excluding 1 unless $(m-n) \equiv 0 \pmod{(k+2)}$.

Therefore, whenever $(m-n) \not\equiv 0 \pmod{(k+2)}$ the second sum is $-1$ and the expression (D.19), and consequently (D.18), vanish. From now on we assume that there exists a $q \in \mathbb{Z}$ such that $m - n + q(k+2) = 0$. Then (D.19) reduces to:

\[
\sum_{a = 1}^{k+1} \sum_{b = 1}^{a} e^{\frac{2\pi i}{k+2} (m+1-a) - b(n+1)} = -e^{-\frac{\pi i}{k+2} (n+1)} \frac{2i \sin \left( \frac{\pi (n+1)}{k+2} \right)}{2i \sin \left( \frac{\pi (n+1)}{k+2} \right)} (k + 2)
\] (D.20)

Substituting (D.20), (D.10) and (D.12) in (D.18) we find:

\[
-\frac{i}{2} \int_{\mathbb{C}} \omega_m \wedge \tilde{\omega}_n = \frac{\pi}{k+2} \frac{\Gamma \left( \frac{m+1}{k+2} + q \right)}{\Gamma \left( \frac{k-m+1}{k+2} \right)}
\] (D.21)

Substituting this into (D.3) and using (D.1) we get the extremal correlators on $S^2$ (4.41b).
