Abstract

We show that an automorphism of a unital AF $C^*$-algebra with the approximate Rohlin property has the Rohlin property. This generalizes a result of Kishimoto. Using this we show that the shift automorphism on the bilateral $C^*$-algebra associated with an aperiodic irreducible shift of finite type has the Rohlin property.

Key words: Rohlin property, automorphism, AF algebra, shift of finite type

1 Introduction

The Rohlin Lemma is one of the foundations of ergodic theory. The simple idea of levels of a stack moving almost cyclically under a transformation has proved to be an important and powerful tool. In 1975, A. Connes proved a “noncommutative analogue of the very useful tower theorem of Rohlin” for automorphisms of von Neumann algebras ([5]). The notion of a Rohlin property for automorphisms of $C^*$-algebras is due to Herman and Ocneanu ([7]). It is useful in the study of automorphisms up to inner automorphism (see, for example, [3,4,6,9,8,10,11]). Evans and Kishimoto showed in [6] that two automorphisms of an AF $C^*$-algebra having the Rohlin property are outer conjugate if they induce the same action on $K_0$. At present, only a few classes of automorphisms of $C^*$-algebras are known to possess the Rohlin property.

Our work deals with the bilateral $C^*$-algebras associated with shifts of finite type, studied in [13,17,18]. The shift map on the shift space induces an automorphism of the $C^*$-algebra.

Email address: cholton@math.utexas.edu (Charles G. Holton)
Our main result is that these automorphisms have the Rohlin property. It follows from the result of Evans and Kishimoto in [6] that the crossed-product of the bilateral $C^*$-algebra with the $\mathbb{Z}$-action of the automorphism is determined up to isomorphism by its $K$-theory. Krieger showed in [13] that $K$-theory for shifts of finite type is an invariant for shift equivalence, and thus crossed-product algebras arising from shift equivalent shifts of finite type are isomorphic.

We define the Rohlin property and the approximate Rohlin property in Section 2. We also prove a few lemmas about projections and partial isometries in $C^*$-algebras for use in the later sections. In Section 3 we prove that for unital AF algebras the approximate Rohlin property implies the Rohlin property. This improves the result of Kishimoto in [8], where it is shown for for unital simple AF algebras whose $K_0$ group has finite rank and no infinitesimals. We need this more general result because the $K_0$ groups for the algebras we are considering usually have infinitesimals. We show that even less than the approximate Rohlin property is needed to deduce the Rohlin property.

The construction and basic properties of the bilateral $C^*$-algebra and the automorphism associated with a shift of finite type are given in Section 4. This is the algebra associated with one of Krieger’s $K$-theoretic invariants in [13], although the algebra itself is not discussed there. It is a special case of Ruelle’s construction in [17]. Wagoner studied this and two other algebras in [18].

We discuss shift equivalence and the relationship with the automorphism in Section 5. We show that $K_0$ for a bilateral $C^*$-algebra has no infinitesimals if and only if the shift of finite type is shift equivalent to a full shift. Finally, in Section 6 we prove that the automorphism of the bilateral $C^*$-algebra associated with an irreducible aperiodic shift of finite type has the Rohlin property. (This may be deduced for full shifts from the result of Kishimoto in [12].) It follows that the crossed product algebra is no stronger an invariant than the $K$-theoretic invariants introduced in [13]. It is in fact weaker because one can easily show that the full 2 shift and the full 4 shift have isomorphic crossed product algebras. We still do not know whether the pair consisting of the bilateral $C^*$-algebra and the automorphism associated with a shift of finite type is a stronger invariant than shift equivalence.

2 Definitions and basic lemmas

Let $A$ be a unital $C^*$-algebra and write 1 for the identity of $A$. We quote a definition from [8].

Definition 2.1 An automorphism $\alpha$ of a unital $C^*$-algebra $A$ has the Rohlin property if
for any $k \in \mathbb{N}$ there are positive integers $k_1, \ldots, k_m \geq k$ satisfying the following condition:

For any finite subset $F$ of $A$ and $\varepsilon > 0$ there are projections $e_{i,j}$, $i = 0, \ldots, m-1$, $j = 0, \ldots, k_i - 1$ in $A$ such that

1. $\sum_{i=0}^{m-1} \sum_{j=0}^{k_i-1} e_{i,j} = 1$,
2. $\|\alpha(e_{i,j}) - e_{i,j+1}\| < \varepsilon$,  
3. $\|[x,e_{i,j}]\| < \varepsilon$,

for $i = 0, \ldots, m-1$, $j = 0, \ldots, k_i - 1$, and $x \in F$, where $e_{i,k_i} = e_{i,0}$.

**Notation.** A stack of height $m$ for $\alpha$ is a family of orthogonal projections $f_0, f_1, \ldots, f_{m-1}$ such that $\alpha(f_i) = f_{i+1}$, $i = 0, 1, \ldots, m - 2$. By an $\varepsilon$-approximate stack we mean a family of orthogonal projections $f_0, f_1, \ldots, f_{m-1}$ such that $\|\alpha(f_i) - f_{i+1}\| < \varepsilon$, $i = 0, 1, \ldots, m - 2$. We call a stack [or an $\varepsilon$-approximate stack] $f_0, f_1, \ldots, f_{m-1}$ cyclic if $\alpha(f_{m-1}) = f_0$ [resp. if $\|\alpha(f_{m-1}) - f_0\| < \varepsilon$].

**Remark 2.2** From a stack $f_0, f_1, \ldots, f_{nm-1}$ of height $nm$ we can construct a stack $e_0, e_1, \ldots, e_{m-1}$ of height $m$ having the same sum by taking $e_j = \sum_{i=0}^{n-1} f_{im+j}$, and if $\alpha(f_{nm-1}) = f_0$ then $\alpha(e_{m-1}) = e_0$. See Figure 1.

For a compact space $X$ we write $C(X)$ for the $C^*$-algebra of complex-valued continuous functions on $X$ under the supremum norm. The unital $C^*$-subalgebra generated by $a \in A$ is denoted $C^*(a)$. We need a few basic approximation results for $C^*$-algebras. The proofs use standard techniques in spectral theory.

**Lemma 2.3** If $e$ and $f$ are projections in $A$ with $\|ef\| < 1/4$ then there is a projection $g$ such that $e \perp g$ and $\|f - g\| < 4\|ef\|$. 

\[
\begin{array}{cccccc}
 f_{m-1} & f_{2m-1} & \cdots & f_{nm-1} & e_{m-1} \\
 \uparrow \alpha & \uparrow \alpha & \cdots & \uparrow \alpha & \uparrow \alpha \\
 \vdots & \vdots & \ddots & \vdots & \vdots \\
 \uparrow \alpha & \uparrow \alpha & \cdots & \uparrow \alpha & \uparrow \alpha \\
 f_1 & f_{m+1} & \cdots & f_{(n-1)m+1} & e_1 \\
 \uparrow \alpha & \uparrow \alpha & \cdots & \uparrow \alpha & \uparrow \alpha \\
 f_0 & f_m & \cdots & f_{(n-1)m} & e_0 \\
\end{array}
\]
Proof. With $e, f$ as in the hypothesis, $(1 - e)f(1 - e)$ is self-adjoint and close to $f$,
\[
\| (1 - e)f(1 - e) - f \| = \| ef(e - 1) - fe \| \leq \| ef \| \| e - 1 \| + \| fe \| = 2 \| ef \| .
\]
Since $\text{sp}(f) \subset \{0, 1\}$, we have $\text{sp}((1 - e)f(1 - e)) \subset B_{2\|ef\|}(0) \cup B_{2\|ef\|}(1)$, where $B_{\delta}(x)$ denotes the ball of radius $\delta$ centered at $x$. The function $\varphi$ on $\text{sp}((1 - e)f(1 - e))$ which is 0 on $B_{2\|ef\|}(0)$ and 1 on $B_{2\|ef\|}(1)$ is a projection in $C'(\text{sp}((1 - e)f(1 - e)))$ with $\sup |\varphi(x) - x| < 2\|ef\|$, so the continuous functional calculus grants us a projection $g \in C^*((1 - e)f(1 - e))$ with $\| g - (1 - e)f(1 - e) \| < 2\|ef\|$. Now $eg = 0$ (since $e(1 - e) = 0$) and $\| f - g \| \leq \| f - (1 - e)f(1 - e) \| + \| (1 - e)f(1 - e) - g \| < 4\|ef\|$ as desired. □

Lemma 2.4 If $e, f$ are projections in $A$ with $\| e - f \| < 1/2$ then there is a unitary $u \in A$ with $\| 1 - u \| \leq 4\| e - f \|$ and $u^*eu = f$.

Proof. Set $z = 2ef - e - f + 1$. One readily checks that $ez = ef = zf$, and $z$ is invertible since $\| z - 1 \| = \| e(f - e) + (e - f)f \| \leq 2\| e - f \| < 1$. Consider the polar decomposition $z = ua$ where $u$ is a unitary and $a = (z^*z)^{1/2}$. We have $fz^*z = (zf)^*z = (ez)^*z = z^*ez = z^zf$, i.e., $z^z$ commutes with $f$, and since $a \in C^*(z^*z)$ we see that $a$ also commutes with $f$. Thus $u^*eu = az^1eza^{-1} = afa^{-1} = f$. Finally,
\[
\| 1 - u \| \leq \| 1 - z \| + \| z - u \| = \| 1 - z \| + \| 1 - a \| \leq \| 1 - z \| + \| 1 - z \| \leq 4\| e - f \| .
\]
□

Lemma 2.5 If $\{e_1, e_2, \ldots, e_n\}$ and $\{f_1, f_2, \ldots, f_n\}$ are families of orthogonal projections in $A$ with $\| e_i - f_i \| < \varepsilon < 1/2n$ for each $i$ then there is a unitary $u \in A$ such that $\| 1 - u \| < 8n\varepsilon$ and $u^*e_iu = f_i$ for each $i$.

Proof. Let $e_0 = 1 - \sum_{i=1}^{n} e_i$ and $f_0 = 1 - \sum_{i=1}^{n} f_i$. By the triangle inequality, $\| e_0 - f_0 \| \leq n\varepsilon$. By Lemma 2.4 we can for each $i$ choose a unitary $u_i$ with $\| 1 - u_i \| < 4\| e_i - f_i \|$ such that $u_i^*e_iu_i = f_i$. Set $u = \sum_{i=0}^{n} e_iu_i$. Then $u$ is a unitary with $u^*e_iu = f_i$ for each $i$ and
\[
\| 1 - u \| \leq \sum_{i=0}^{n} \| e_i - u_i e_i \| \leq \sum_{i=0}^{n} \| 1 - u_i \| \leq 8n\varepsilon .
\]
□

Lemma 2.6 If $e$ and $f$ are projections in $A$ and $p \in A$ is a partial isometry with $\| p^*p - e \| < \varepsilon < 1/2$ and $\| pp^* - f \| < \varepsilon$ then there is a partial isometry $q \in A$ with $q^*q = e$ and $qq^* = f$ and $\| p - q \| < 8\varepsilon$.

When $e, f \in A$ are equivalent projections we write $e \sim f$; i.e., $e \sim f$ if there exists $p \in A$ such that $p^*p = e$ and $pp^* = f$. We state two facts about equivalence classes and $K_0(A)$ and refer the reader to [1] for proofs.
Lemma 2.7 If $A$ has cancellation then for any $g \in K_0(A)_+$ with $g < [1]$ there is a projection $e \in A$ with $[e] = g$.

Definition 2.8 When $K_0(A)$ is torsion-free, the rank of $K_0(A)$ is the dimension of the rational vector space $K_0(A) \otimes \mathbb{Q}$.

Lemma 2.9 Suppose $A$ has cancellation. Write $[\cdot]$ for equivalence class in $K_0(A)$. If $e$ and $f$ are projections in $A$ such that $[e] \leq [f]$ then there is a partial isometry $p \in A$ with $pp^* \leq f$ and $p^*p = e$, and $pp^* = f$ if $[e] = [f]$.

Many proofs that a certain automorphism has the Rohlin property use an intermediate concept similar to the following, which comes from [8].

Definition 2.10 An automorphism $\alpha$ of a unital AF algebra $A$ has the approximate Rohlin property if for any $m, n \in \mathbb{N}$, any $\varepsilon > 0$, and any finite-dimensional $C^*$-subalgebra $B$ of $A$ there is an $\varepsilon$-approximate cyclic stack $e_0, e_1, \ldots, e_{m-1}$ in $A \cap B'$ such that

1. $[e_0] = [e_1] = \cdots = [e_{m-1}]$ and
2. $[e_0] \geq n \left[ 1 - \sum_{i=0}^{m-1} e_i \right],$

where $[\cdot]$ denotes the equivalence class in $K_0(A \cap B')$.

Remark 2.11 Setting $n = 1$ in Definition 2.10 changes nothing since for $n = \ell$ we can start with a $\varepsilon_\ell$-approximate stack of height $\ell m$ satisfying the definition for $n = 1$ and then the construction in Remark 2.2 yields an $\varepsilon$-approximate stack of height $m$ satisfying the definition for $n = \ell$. We can further simplify the definition by dropping the requirement that the approximate stack be cyclic, as we shall see later.

3 General results on the Rohlin property

Theorem 3.1 An automorphism of unital AF algebra having the approximate Rohlin property also has the Rohlin property.

Remark 3.2 The approximate Rohlin property was introduced in [2], in the context of the one-sided shift on the CAR algebra $\hat{\otimes} M_2$. Definition 2.10 generalizes the idea to arbitrary AF algebras. In [8] it is shown (Theorem 4.1) that the approximate Rohlin property implies the Rohlin property for unital simple AF algebras when $K_0$ is of finite rank and has no infinitesimal elements. In this setting the Rohlin property also implies the approximate Rohlin property, but we do not know whether the converse of Theorem 3.1 holds in general.
Proof of Theorem 3.1. Given $m, \varepsilon$ and $F$ we shall use the approximate Rohlin property to construct a partition of unity by projections $e_{0,0}, \ldots, e_{0,m-1}, e_{1,0}, \ldots, e_m$ satisfying Definition 2.1. The technique is similar to that in the proof of Lemma 4.4 in [8] in which the additional assumptions (that $\mathcal{K}_0(A)$ be of finite rank and have no infinitesimals) are used. There is also an error or omission in the proof there which we have corrected.

We shall assume that the elements of $F$ are of norm 1 as there is no loss of generality in doing so. The construction depends on parameters $n, \ell \in \mathbb{N}$ (which determine heights of intermediate stacks) and $\varepsilon > 0$. We require that $n \equiv 1 \mod m+1$, $\ell > 4$, and $\varepsilon < (Nm)^{-3}$, where $N = n\ell$.

Let $B$ be a finite dimensional $C^*$-subalgebra of $A$ such that $\text{dist}(\alpha^{-k}(x), B) < (Nm)^{-3}$ for all $x \in F, k = 0, 1, \ldots, Nm - 1$. Let $e_0, \ldots, e_{N-1}$ be an $\varepsilon$-approximate cyclic stack in $A \cap B'$ such that

$$[e] \leq [e_0] = [e_1] = \cdots = [e_{N-1}],$$

where $[\cdot]$ denotes equivalence class in $\mathcal{K}_0(A \cap B')$ and

$$e = 1 - \sum_{i=0}^{N-1} e_i.$$

By Lemma 2.9 there is a partial isometry $p_0$ in $A \cap B'$ such that $p_0^*p_0 = e$ and $p_0p_0^* < e_0$. We have

$$\|\alpha(p_0)^*\alpha(p_0) - e\| = \|\alpha(e) - e\| < Nm\varepsilon$$

and since

$$\alpha(p_0)\alpha(p_0)^* < \alpha(e_0),$$

$\alpha(p_0)\alpha(p_0)^*$ is within $\varepsilon$ of some subprojection of $e_1$. By Lemma 2.6 there is a partial isometry $p_1 \in A$ such that $p_1^*p_1 = e$ and $p_1p_1^* < e_1$ and $\|\alpha(p_0) - p_1\| \ll (Nm)^{-3}$, provided $\varepsilon$ is chosen sufficiently small. Continuing inductively, assuming $\varepsilon$ is small enough, we can find partial isometries $p_k, k = 0, 1, \ldots, Nm - 1$, such that $p_k^*p_k = e$ and $p_kp_k^* < e_k$ for each $k$ and

$$\|\alpha(p_k) - p_{k+1}\| < (Nm)^{-3} \text{ for } k = 0, 1, \ldots, Nm - 2.$$

If $x \in F$ and $k \in \{0, 1, \ldots, Nm - 1\}$ then

$$\|[p_k, x]|| \leq \|p_kx - \alpha^k(p_0)x\| + \|[\alpha^k(p_0), x]\| + \|x\alpha^k(p_0) - xp_k\|$$

$$\leq 2\|p_k - \alpha^k(p_0)\| + \|[p_0, \alpha^{-k}(x)]\|$$

$$\leq 2k(Nm)^{-3} + 2\text{dist}(\alpha^{-k}(x), B)$$

$$< 2(Nm)^{-2}.$$
Fig. 2. The situation in Theorem 3.1.

For $k = 0, 1, \ldots, mn - 1$ the partial isometry

$$q_k = \frac{1}{\sqrt{\ell}} \sum_{j=0}^{\ell-1} p_{jmn+k}$$

has domain $e$ and range $< \sum_{j=0}^{\ell-1} e_{jmn+k}$. By the triangle inequality,

$$\| \alpha(q_k) - q_{k+1} \| < \sqrt{\ell}(Nm)^{-2} < 3/\sqrt{\ell} \quad k = 0, 1, \ldots, m - 2,$$

$$\| \alpha(q_{mn-1}) - q_0 \| < \frac{1}{\sqrt{\ell}} \left[ (\ell - 1)(Nm)^{-2} + 2 \right] < 3/\sqrt{\ell}, \text{ and}$$

$$\| [q_k, x] \| < 2\sqrt{\ell}(Nm)^{-2}, \quad x \in F, \quad k = 0, 1, \ldots, m - 1.$$

Define $e_{0,k}$ for $k = 0, 1, \ldots, m - 1$ by setting

$$e_{0,k} = \sum_{j=0}^{n-1} e_{j+m+k} - \sum_{j=0}^{n-1} q_{j+m+k}q_{j+m+k}^*.$$

Another application of the triangle inequality, together with the bounds above, yields

$$\| \alpha(e_{0,k}) - e_{0,k+1} \| < N(Nm)^{-3} + 6n/\sqrt{\ell} < 7n/\sqrt{\ell} \quad k = 0, 1, \ldots, m - 1,$$

where $e_{0,m} = e_{0,0}$, and

$$\|[e_{0,k}, x]\| < 2N(Nm)^{-3} + 4n\sqrt{\ell}(Nm)^{-2} < 5/N, \quad x \in F, \quad k = 0, 1, \ldots, m - 1,$$

where we have used the fact that $\|[e_i, x]\| < 2(Nm)^{-3}$.

We claim that the $C^*$-subalgebra $D$ generated by $\{q_0, q_1, \ldots, q_{mn-1}\}$ is isomorphic to $M_{mn+1}$. Indeed, $D$ has $mn + 1$ orthogonal projections, $e, q_0q_0^*, q_1q_1^*, \ldots, q_{mn-1}q_{mn-1}^*$, and for each $i$, $q_i$ is a partial isometry from $e$ to $q_iq_i^*$. Thus for each pair $i, j$, $q_jq_i^*$ is a partial isometry from $q_jq_j^*$ to $q_iq_i^*$, and we see that the generators for $D$ are part of a full set of
matrix units (which they generate) for an $mn + 1$-dimensional $C^*$-algebra. Let $u$ be the unitary in $D$ defined by

$$(\text{Ad } u)(q_k) = q_{k+1}$$

for $k = 0, 1, \ldots, mn - 1$, where $q_{mn} = q_0$, and

$$(\text{Ad } u)(e) = e.$$ 

From the triangle inequality we obtain the generous estimate

$$\|\alpha|_D - (\text{Ad } u)|_D\| < 3(mn + 1)^2 / \sqrt{\ell}.$$ 

The eigenvalues of $u$ are $e^{2\pi i j / mn}$, $j = 0, 1, \ldots mn$, and there is a unitary $v \in D$ with eigenvalues $e^{2\pi i j / mn+1}$, $j = 0, 1, \ldots mn$, such that $\|u - v\| < \frac{2\pi}{mn}$. To see this, note that unitaries in $M_{mn+1}$ can be diagonalized by unitaries in $M_{mn+1}$ and there is a path of diagonal unitaries from $\text{diag}(1, 2\pi i / mn, \ldots, 2\pi i (mn - 1) / mn, 1)$ to $\text{diag}(1, \frac{2\pi i}{mn+1}, \ldots, \frac{2\pi i (mn-1)}{mn+1}, \frac{2\pi i mn}{mn+1})$ having length $\frac{2\pi}{mn+1}$. There is a projection $r$ in $D$ such that $\sum_{j=0}^{mn}(\text{Ad } v)^j(r)$ equals the identity in $D$ ($v$ acts as a permutation of least period $mn + 1$ on some orthonormal basis for $C^{mn+1}$; we can take $r$ to be the projection onto one of these basis vectors) and we set

$$e_{1,k} = \sum_{j=0}^{\frac{mn+1}{m+1} - 1} (\text{Ad } v)^j(m+1)(r), \quad k = 0, 1, \ldots, m,$$

which makes sense because $n \equiv 1 \pmod{m+1}$. For $k = 0, 1, \ldots, m$ we have $(\text{Ad } v)(e_{1,k}) = e_{1,k+1}$ and

$$\|\alpha(e_{1,k}) - e_{1,k+1}\| \leq \|\alpha(e_{1,k}) - (\text{Ad } u)(e_{1,k})\| + \|(\text{Ad } u)(e_{1,k}) - (\text{Ad } v)(e_{1,k})\|$$

$$\leq 3(mn + 1)^2 / \sqrt{\ell} + \frac{4\pi}{nm},$$

where $e_{1,m+1} = e_{1,0}$. For $x \in F$ we bound $\|e_{1,k,x}\|$ by $4(nm + 1)^2 \sqrt{\ell (Nm)^2} < 4 / \sqrt{\ell}$, using the triangle inequality with our previous estimates.

Now $\{e_{i,j} : i = 0, 1, j = 0, 1, \ldots, m + i - 1\}$ is a partition of unity by projections. Our estimates show that we achieve the desired tightness in our approximate Rohlin stacks if we take $n > \frac{8\pi}{me}$ and $\ell > \frac{36(mn+1)^4}{e^2}$. \qed

Inspection of the proof shows that one can deduce the Rohlin property from weaker hypotheses, by simply replacing the hypotheses involving $K_0$ in the approximate Rohlin property with a new requirement that a certain partial isometry exists. This implies an inequality in $K_0$ but is not implied by it for algebras without nice properties like cancellation.

**Theorem 3.3** Let $\alpha$ be an automorphism of a unital $C^*$-algebra $A$ with the property that
for any finite subset $F$ of $A$ and for any $m \in \mathbb{N}$, $\epsilon > 0$, there are projections $e_0, e_1, \ldots, e_{m-1}$ in $A$ and a partial isometry $p$ in $A$ such that

1. $\|e_i e_j\| < \epsilon$ for $i, j = 0, 1, \ldots, m - 1, i \neq j$,
2. $\|\alpha(e_i) - e_{i+1}\| < \epsilon$ for $i = 0, 1, \ldots, m - 1$, where $e_m = e_0$,
3. $p^*p = 1 - \sum_{i=0}^{m-1} e_i$ and $pp^* - e_0 < \epsilon$,
4. $\|[x,y]\| < \epsilon$ for any $x \in F, y \in \{e_0, p\}$.

Then $\alpha$ has the Rohlin property.

**Proof.** We have assumed what we had to deduce from $K$-theoretic data in the proof of Theorem 3.1, and we repeat that proof with minor changes. Use $\bigcup_{i=0}^{-Nm+1} \alpha^{-i}(F)$ in place of $F$. Perturb the $e_i$ so that they are orthogonal (Lemma 2.5). Let $p_0$ be a partial isometry close to $p$ for which $p_0^*p_0 = 1 - \sum_{i=0}^{Nm-1} e_i$ and $p_0p_0^* = e_0$ (Lemma 2.9). The rest of the proof is the same. □

We end the section with a condition which is sometimes easier to verify, to be used in the proof of Theorem 6.1. The hypothesis that the top of the stack be taken near the bottom is removed at the expense of requiring a partial isometry between the first two levels of the stack. This implies equality of the $[e_i]$ always, but is not implied by it in algebras without cancellation.

**Theorem 3.4** Let $\alpha$ be an automorphism of a unital $C^*$-algebra $A$ with the property that for any finite subset $F$ of $A$ and for any $m \in \mathbb{N}$, $\epsilon > 0$, there are an $\epsilon$-approximate stack $e_0, e_1, \ldots, e_{m-1}$ for $\alpha$ and partial isometries $p, q$ in $A$ such that

1. $p^*p = 1 - \sum_{i=0}^{m-1} e_i$ and $pp^* < e_0$,
2. $q^*q = e_0$ and $qq^* = e_1$,
3. $\|[x,y]\| < \epsilon$ for any $x \in F, y \in \{p, q\}$.

Then $\alpha$ has the Rohlin property.

**Remark 3.5** We could allow $e_i$ to be almost orthogonal instead of orthogonal and relax the equalities involving $p$ and $q$ to approximations as in Theorem 3.3 and the conclusion still holds.

**Proof.** We show that $\alpha$ satisfies the hypothesis of Theorem 3.3. Our proof uses many of the same ideas as in Lemmas 2.1 and 4.3 in [8]. The construction depends on parameters $\ell \in \mathbb{N}, \epsilon > 0$ to be specified later. Let $F$ be a finite set, $m \in \mathbb{N}$, and $\epsilon > 0$. Let $e_0, e_1, \ldots, e_{(\ell-1)(m+2)m-1}$ be an $\epsilon$-approximate stack for $\alpha$ and let $p, q$ be partial isometries in $A$ such that
\[ p^* p = 1 - \sum_{i=0}^{(\ell-1)(m+2)m-1} e_i \text{ and } pp^* < e_0, \]
\[ q^* q = e_0 \text{ and } qq^* = e_1, \]
\[ \| [x, y] \| < \varepsilon \text{ for all } x \in \bigcup_{i=0}^{(\ell-1)(m+2)} \alpha^{-i}(F), \ y \in \{p, q\}. \]

By Lemma 2.5 there is a unitary \( u \in A \) such that
\[ \| 1 - u \| < 8(\ell - 1)(m + 2)m\varepsilon \]
and
\[ u\alpha(e_i)u^* = e_{i+1}, \ i \in \{0, 1, \ldots, (\ell - 1)(m + 2)m - 2\}. \]

Write \( \beta \) for \( (\text{Ad } u) \circ \alpha \). Define a system of matrix units \( \{q_{i,j} : 0 \leq i, j \leq (\ell - 1)(m + 2)m - 1\} \) by setting
\[ q_{i,i} = e_i \]
and for \( i < j \)
\[ q_{i,j} = \beta^i(q)\beta^{i+1}(q) \cdots \beta^{j-1}(q), \quad q_{j,i} = q_{i,j}^*. \]

One readily checks that
\[ q_{i,j}q_{i',j'} = \delta_{j,j'}q_{i,j'}, \]
and
\[ \beta(q_{i,j}) = q_{i+1,j+1}, \ 0 \leq i, j \leq (\ell - 1)(m + 2)m - 2. \]

For \( j = 0, 1, \ldots, m - 1 \) put
\[
f_j = \sum_{i=0}^{(m+1)(\ell-1)-1} \left[ \frac{i+1}{\ell} q_{im+j,im+j} + \frac{\ell - 1 - i}{\ell} q_{((m+1)(\ell-1)+i)m+j,((m+1)(\ell-1)+i)m+j} \right. \\
+ \sqrt{(i+1)(\ell-1-i)} q_{im+j,((m+1)(\ell-1)+i)m+j} \\
+ \sqrt{(i+1)(\ell-1-i)} q_{((m+1)(\ell-1)+i)m+j,im+j} \\
+ \left. \sum_{i=\ell-1}^{(m+1)(\ell-1)-1} q_{im+j,im+j} \right].
\]

Then \( f_0, f_1, \ldots, f_{m-1} \) is a stack of height \( m \) for \( \beta \). We have
\[
\beta(f_{m-1}) - f_0 = \frac{1}{\ell} \sum_{i=0}^{(m+1)(\ell-1)-1} \left[ e_{((m+1)(\ell-1)+i)m} - e_{im} \right] \\
+ \left( \sqrt{i(\ell-i)} - \sqrt{(i+1)(\ell-1-i)} \right) (q_{im,((m+1)(\ell-1)+i)m} + q_{((m+1)(\ell-1)+i)m,im}),
\]
and since, for \( i = 0, 1, \ldots, \ell - 1, \)
\[
\left| \sqrt{i(\ell - i)} - \sqrt{(i + 1)(\ell - 1 - i)} \right| \leq \sqrt{|i(\ell - i) - (i + 1)(\ell - 1 - i)|} = \sqrt{|1 + 2i - \ell|} < \sqrt{\ell}
\]
we see from orthogonality that
\[
\| \beta(f_{m-1}) - f_0 \| < \frac{1}{\ell} + \frac{1}{\sqrt{\ell}}.
\]
This shows that \( f_0, f_1, \ldots, f_{m-1} \) is a \( \frac{2}{\sqrt{\ell}} \)-approximate cyclic stack for \( \beta \), and thus by choosing \( \varepsilon \) small enough and \( \ell \) large enough we can ensure that \( f_0, f_1, \ldots, f_{m-1} \) is an \( \varepsilon \)-approximate cyclic stack for \( \alpha \). We have constructed an approximate cyclic stack from an approximate noncyclic stack, and the sum of this new stack is smaller than the sum of the old one by \( m(\ell - 1) \) projections equivalent to \( e_0 \), specifically,
\[
1 - \sum_{j=0}^{m-1} f_j = p^* p + \sum_{j=0}^{m-1} \sum_{i=0}^{\ell-2} \left\{ \frac{\ell - 1 - i}{\ell} q_{im+j,im+j} + \frac{i + 1}{\ell} q_{(m+1)(\ell-1)+i}m+j,(m+1)(\ell-1)+i)m+j + \sqrt{\frac{(i + 1)(\ell - 1 - i)}{\ell}} q_{im+j,(m+1)(\ell-1)+i)m+j} + \frac{(i + 1)(\ell - 1 - i)}{\ell} q_{((m+1)(\ell-1)+i)m,j+im+j} \right\}.
\]
The base of our new stack, \( f_0 \), has a subprojection equivalent to \( 1 - \sum_{j=0}^{m-1} f_j \), indeed
\[
r = \sum_{j=0}^{m-1} \sum_{i=0}^{\ell-2} \left( \sqrt{\frac{\ell - 1 - i}{\ell}} q_{(\ell+im+j-1)m,im+j} + \sqrt{\frac{i + 1}{\ell}} q_{(\ell+im+j-1)m,(m+1)(\ell-1)+i)m+j} \right) + \left( \sqrt{\frac{1}{\ell}} e_0 + \sqrt{\frac{\ell - 1}{\ell}} q_{(m+1)(\ell-1)m,0} \right) p
\]
is a partial isometry satisfying
\[
rr^* = 1 - \sum_{j=0}^{m-1} f_j \quad \text{and} \quad r^* r < f_0.
\]
The \( q_{i,j} \) almost commute with \( F \) if \( \varepsilon \) is chosen small relative to \( 1/\ell \), and since \( f_0, \ldots, f_{m-1} \) and \( r \) are linear combinations of the \( q_{i,j} \) these too almost commute with \( F \). By Theorem 3.4, \( \alpha \) has the Rohlin property. \( \square \)
Remark 3.6 In the proof of Theorem 3.4 we constructed an approximate cyclic stack \( f_0, f_1, \ldots, f_{m-1} \) from an approximate (noncyclic) stack \( e_0, e_1, \ldots, e_{Nm-1} \) using only the partial isometry \( q \) from \( e_0 \) to \( e_1 \). To construct the partial isometry \( r \) from \( 1 - \sum f_j \) to a subprojection of \( f_0 \) we needed the partial isometry \( p \) from \( 1 - \sum e_i \) to a subprojection of \( e_0 \). The \( f_j \) and \( r \) lie in \( C^*(p, q, \alpha(q), \ldots, \alpha^{Nm-1}(q)) \) and the proof shows that these can be made to almost commute with any finite set provided the \( e_i \) and \( q \) and \( p \) can be made to almost commute with any finite set. This justifies the last line of Remark 2.11, since if we can make the \( f_j \) and \( r \) almost commute with a system of matrix units for \( B \) then a small inner perturbation takes the \( f_j \) and \( r \) into the commutant of \( B \).

4 Shifts of finite type and the bilateral algebras

We refer the reader to the excellent book of Lind and Marcus [14] for background on shifts of finite type. Let \( T \) be a nonnegative integral \( r \times r \) matrix. Let \( G_T \) be the directed graph with \( r \) vertices labeled \( 1, 2, \ldots, r \) and having \( T(i,j) \) edges from vertex \( i \) to vertex \( j \). Write \( E_T \) for the edge set of \( G_T \), and for \( e \in E_T \) let \( i(e) \) and \( t(e) \) be the initial and terminal vertices of \( e \), respectively.

Definition 4.1 A path on \( G_T \) is a finite or infinite sequence \( x \) in \( E_T \) such that \( i(x_{i+1}) = t(x_i) \) for all relevant indices \( i \).

Notation. For a finite path \( x = x_0x_1 \ldots x_{\ell-1} \) we let \( i(x) = i(x_0) \) and \( t(x) = t(x_{\ell-1}) \) and we write \( |x| = \ell \) for the length of \( x \). By convention, each vertex \( i \) is regarded as a path of length 0 having \( i \) as its initial and terminal vertices. If \( a \) and \( b \) are integers with \( a \leq b \) and \( x \) is a path then we put
\[
x_{[a,b]} = x_ax_{a+1} \ldots x_b
\]
when the right-hand side makes sense.

We use the following fact often.

Lemma 4.2 For \( i, j \in \{1, 2, \ldots, r\} \), the number of paths of length \( \ell \) in \( G_T \) starting at \( i \) and ending at \( j \) is \( T^\ell(i,j) \).

Definition 4.3 The underlying space \( X_T \) of the shift of finite type determined by \( T \) is the set of all bi-infinite paths on \( G_T \).

Definition 4.4 Basic cylinders are sets of the form
\[
cyl(x,k) = \{ y \in X_T : y_{i+k} = x_i \text{ for } 0 \leq i < |x| \},
\]
where \( x = x_0x_1 \ldots x_{|x|-1} \) is a finite path in \( G_T \) and \( k \in \mathbb{Z} \).
Basic cylinders form a basis of clopen sets for a topology on $X_T$ in which $X_T$ is a Cantor set. Though we shall not specifically use a metric it is helpful to think of two points being close if their sequences agree on a large interval of indices about 0.

The paradigm of symbolic dynamics is that all the complexity of a system is encoded in sequence space.

**Definition 4.5** The shift homeomorphism $\sigma_T : X_T \to X_T$ is defined by

$$(\sigma_T((x_i)_{i\in\mathbb{Z}}))_i = x_{i+1}.$$ 

**Example 4.6** The full $n$-shift is the shift of finite type associated with the $1 \times 1$ matrix $(n)$, the underlying space of which is $\{1, 2, \ldots, n\}^\mathbb{Z}$.

We shall assume our matrix $T$ is primitive, i.e., some positive power of $T$ has strictly positive entries, and that $T \neq (1)$. Then $X_T$ is nonempty and $\sigma_T$ is topologically mixing (see, for example, Proposition 4.5.10 of [14]). By the Perron-Frobenius theorem, $T$ has a unique (up to scalar multiplication) strictly positive (right) eigenvector; the corresponding eigenvalue $\lambda_T$ is algebraically simple, greater than 1, and strictly larger in absolute value than any other eigenvalue of $T$. Let $v, w^*$ be positive Perron-Frobenius eigenvectors for $T$ and $T^*$, respectively, normalized so that $w^*v = 1$.

The measure of maximal entropy on $X_T$ is the Markov measure $\mu_T$ defined from transition probabilities

$$p(e) = \lambda_T^{-1}v_{t(e)}/v_{s(e)}, \quad e \in \mathcal{E}_T$$

and stationary distribution

$$\pi_i = w_i v_i, \quad 1 \leq i \leq r$$

by

$$\mu_T(cyl(x, k)) = \pi_{1(x)}p(x_0)p(x_1)\ldots p(x_{|x|-1}) = \lambda_T^{-|x|}w_{1(x)}v_{t(x)}.$$ 

(1)  

(2)

We have the following standard result.

**Lemma 4.7** $\mu_T$ is an ergodic measure on $(X_T, \sigma_T)$ which gives every cylinder positive measure.

We are interested in the symmetric, or bilateral, $C^*$ algebras associated to shifts of finite type. The earliest references of which we are aware for the these $C^*$-algebras are from 1988, a construction by Wagoner in [18] specifically for shifts of finite type, and Ruelle’s more general construction in [17]. These algebras are implicit in Krieger’s earlier $K$-theoretic invariants for shifts of finite type, introduced in [13] (1982).
We write $M_n$ for the $C^*$-algebra of complex $n \times n$ matrices. For integers $a \leq b$ let $H_T^{[a,b]}$ be the $C^*$-algebra generated by matrix units $E_{x,y,a,b}$, where $x$ and $y$ are paths in $G_T$ of length $b - a + 1$ with $i(x) = i(y)$ and $t(x) = t(y)$. Matrix units means

$$E_{x,y,a,b}E_{x',y',a,b} = \delta_{y,x'}E(x,y',a,b)$$

and

$$E_{x,y,a,b}^* = E_{y,x,a,b}.$$

**Lemma 4.8** For each interval $I = [a,b]$ we have

$$H_T^I \cong \bigoplus_{i,j} M_{T|I|+1(i,j)};$$

one summand for each pair of vertices, the size of the $ij$th being the number of paths of length $|I| + 1$ in $G_T$ beginning at vertex $i$ and ending at vertex $j$.

**Proof.** For each pair of vertices $i, j$, enumerate the $T|I|+1(i,j)$ paths of length $|I| + 1$ in $G_T$ with initial vertex $i$ and terminal vertex $j$. If $x, y$ are the $k$th and $\ell$th such paths from $i$ to $j$ then we identify $E_{x,y,a,b}$ with the $T|I|+1(i,j) \times T|I|+1(i,j)$ matrix having a 1 in the $k,\ell$th position and zeros everywhere else, and we embed this in $\bigoplus_{i,j} M_{T|I|+1(i,j)}$ by taking the direct sum of it with matrices of zeros for the other summands. It is easy to see that this induces an isomorphism. $\square$

Let $I = [a,b]$ and $J = [c,d]$ be intervals with $I \subset J$. Let $\psi_{T,I,J} : H_T^I \to H_T^J$ be the embedding defined for matrix units by

$$\psi_{T,I,J}(E_{x,y,a,b}) = \sum\{E_{z,u,c,d} : z_{[a-c,a+b-c]} = x \text{ and } u_{[a-c,a+b-c]} = y\}. \quad (3)$$

**Lemma 4.9** The matrix of partial multiplicities for $\psi_{T,I,J}$ is the transpose of $(T^*)^{(a-c)} \otimes T^{(d-b)}$.

**Proof.** Simply count the number of paths $z$ and $u$ which extend $x$ and $y$, respectively, using Lemma 4.2. $\square$

**Lemma 4.10** If $I \subset J \subset K$ then

$$\psi_{T,I,K} = \psi_{T,I,K} \circ \psi_{T,I,J}.$$

**Proof.** This follows from the fact that if $z$ is a path extending $u$ and $u$ is a path extending $x$ then $z$ is a path extending $x$. $\square$

**Definition 4.11** $A_T$ is the closure of $\lim_{\to}(\varphi_{T,I,J} : H_T^I \to H_T^J)$. 

14
The proof of the following lemma is straightforward and we leave it to the reader.

**Lemma 4.12** $A_T$ is simple and has a unique trace. The trace $\tau_T$ is given on each $H^I_T$ by

$$\tau_T \left( \sum_{x,y} c_{x,y} E_{x,y,a,b} \right) = \sum_x c_{x,x} \mu_T(\text{cyl}(x,0)),$$

where the sums are over all paths of length $|I| + 1$. The trace determines the order on $K_0(A_T)$ up to infinitesimals.

The shift $\sigma_T$ on $X_T$ promotes to an automorphism $\alpha_T$ of $A_T$ defined by

$$\alpha_T(E_{u,v,a,b}) = E_{u,u-1,v,b-1}.$$  (4)

Uniqueness of the trace implies that it is invariant under $\alpha_T$, i.e.,

$$\tau_T \circ \alpha_T = \tau_T.$$

The $C^*$-algebra $C(X_T)$ of continuous complex valued functions on $X_T$ is a subalgebra of $A_T$ in a natural way. Specifically, $\varphi_T : C(X_T) \to A_T$ is defined for characteristic functions of basic cylinders by

$$\varphi_T(\chi_{\text{cyl}(u,k)}) = E_{u,u,k,k+|u|-1}$$

and extended to all of $C(X_T)$ in the usual way. The next two lemmas follow from the definition of $\alpha_T$ in Eq. (4).

**Lemma 4.13** The $C^*$-embedding $\varphi_T$ takes the induced map $f \mapsto f \circ \sigma_T^{-1}$ on $C(X_T)$ to $\alpha_T$, i.e.,

$$\varphi_T(f \circ \sigma_T^{-1}) = \alpha_T(\varphi_T(f)).$$

**Lemma 4.14** The restriction $\alpha_T|H^I_T$ is an isomorphism from $H^I_T$ to $H^{I-1}_T$.

The following is a very useful fact about these algebras.

**Lemma 4.15** If $I$ and $J$ are disjoint intervals then elements of $H^I_T$ commute with elements of $H^J_T$ in $A_T$.

**Proof.** We may assume that $I = [a,b]$ and $J = [c,d]$ with $b < c$. Let $K = [a,d]$. It follows from the definitions that

$$\psi_{t,i,K}(E_{x,y,a,b})\psi_{t,i,K}(E_{x',y',c,d}) = \sum_t E_{xtx',yty',a,d}$$

where the sum is over all paths $t$ from $t(x)$ to $i(x')$ of length $c - b - 1$ and where $xtx'$ means the concatenation of the paths $x, t, x'$, and similarly for $yty'$. Nothing here depends
on the order of multiplication and $\psi_{T,I,K}(E_{x',y',c,d})\psi_{T,J,K}(E_{x,y,a,b})$ is easily seen to be the very same sum.  

\section{5 Shift equivalence}

Shift equivalence and strong shift equivalence for shifts of finite type were introduced by Williams in [19].

\textbf{Definition 5.1} Nonnegative integral square matrices $U, V$ are said to be shift equivalent if there exist nonnegative integral matrices $R, S$ and a positive integer $\ell$ such that

\begin{align*}
RS &= U^\ell \\
SR &= V^\ell \\
SU &= VS \\
UR &= RV.
\end{align*}

Shift equivalence is an equivalence relation. The integer $\ell$ is called the lag of the shift equivalence.

\textbf{Definition 5.2} An elementary strong shift equivalence between nonnegative integral square matrices $U$ and $V$ is a pair of nonnegative integral matrices $R, S$ such that $RS = U$ and $SR = V$. Strong shift equivalence is the equivalence relation generated by elementary strong shift equivalence.

Shifts of finite type $(X_U, \sigma_U)$ and $(X_V, \sigma_V)$ are conjugate if there is a homeomorphism $\rho : X_U \to X_V$ such that $\rho \circ \sigma_U = \sigma_V \circ \rho$ and eventually conjugate if $(X_U, \sigma_U^\ell)$ and $(X_V, \sigma_V^\ell)$ are conjugate for all sufficiently large $\ell$. Williams showed ([19]) that $U$ and $V$ are strong shift equivalent if and only if $(X_U, \sigma_U)$ and $(X_V, \sigma_V)$ are conjugate, and that $U$ and $V$ are shift equivalent if and only if $(X_U, \sigma_U)$ and $(X_V, \sigma_V)$ are eventually conjugate.

The Shift Equivalence Conjecture is the proposition that shift equivalence is the same as strong shift equivalence. The first counterexample was a pair of reducible shifts of finite type found in 1992 by Kim and Roush ([15]). The question for the irreducible case remained open until 1997, when Kim and Roush exhibited in [16] a pair of primitive $7 \times 7$ matrices which are shift equivalent but not strong shift equivalent. The invariant used to prove the matrices are not shift equivalent was the sign-gyration-compatibility-condition class $sgc_2$, which turns out to be the same as Wagoner’s $K_2$-invariant, $\Phi_2$.

There are still many open questions. For one, it is not known whether the conjecture holds for matrices shift equivalent to full shifts. We do not even know if the automorphisms $\alpha_U$ and $\alpha_V$ associated with shift equivalent matrices $U$ and $V$ are conjugate, though they are of course eventually conjugate. We do have the following.
Proposition 5.3 If $U$ and $V$ are shift equivalent primitive matrices then there is an isomorphism $\Psi : A_U \rightarrow A_V$ such that $(\alpha_U)_* = (\Psi^{-1} \circ \alpha_V \circ \Psi)_*$.

Sketch of Proof. This can be proved using the standard bipartite graph construction (see [14], §7.2) to obtain a conjugacy between $(X_U, \sigma_U^\ell)$ and $(X_V, \sigma_V^\ell)$ for some $\ell$. A conjugacy produced in this way induces a isomorphism of $C^*$-algebras with the desired property. □

We now show that our automorphisms are usually not approximately inner. One consequence of this is that we cannot deduce the Rohlin property for $\alpha_T$ from the result of [8].

Notation. For an $s \times s$ integral matrix $S$ we write $\mathcal{R}_S$ for the eventual range of $S$,

$$\mathcal{R}_S = \bigcap_{n \geq 0} (\mathbb{Q}^s)^* S^n.$$ 

By rank considerations, we have $\mathcal{R}_S = (\mathbb{Q}^s)^* S^s$. The eventual rank of $S$ is the dimension of the rational vector space $\mathcal{R}_S \otimes \mathbb{Q}$.

Proposition 5.4 The following are equivalent:

1. $K_0(A_T)$ has no infinitesimals
2. $T$ has eventual rank 1
3. $T$ is shift equivalent to the $1 \times 1$ matrix $(n)$ for some $n \geq 2$
4. $\alpha_T$ is approximately inner.

Proof. 1 $\iff$ 2. As ordered groups, $K_0(A_T) \cong \lim_{\rightarrow} (\mathbb{Z}^r \otimes \mathbb{Z}^r, T^* \otimes T)$, thus

$$\text{rank } K_0(A_T) = \text{rank } \mathcal{R}_{T^* \otimes T} = (\text{rank } \mathcal{R}_T)^2.$$ 

We shall use the fact that $\lim_{\rightarrow} (\mathbb{Z}^r \otimes \mathbb{Z}^r, T^* \otimes T)$ is isomorphic to the (additive) subgroup of $M_r(\mathbb{Q})$ consisting of those matrices $U$ in $T^r M_r(\mathbb{Q}) T^r$ such that $T^n U T^n \in M_r(\mathbb{Z})$ for some $n \in \mathbb{N}$. The positive cone is the set of $U$ such that $T^n U T^n \in M_r(\mathbb{Z}_+)$ for some $n \in \mathbb{N}$. Let us identify $(K_0(A_T), \leq)$ with this ordered group. By Perron-Frobenius theory, $U \in K_0(A_T)_+$ if and only if $wUv > 0$, thus the infinitesimals are precisely those $U$ for which $wUv = 0$. It is possible to replace $v$ with a multiple so that its entries lie in and span $\mathbb{Q}[\lambda_T]$. The same is true of $w$. It follows that we can find $r^2 - \deg \lambda_T$ linearly independent matrices $U_i \in M_r(\mathbb{Z})$ such that $wU_i v = 0$ for each $i$. The infinitesimal subgroup of $K_0(A_T)$ is generated by the matrices $T^r U_i T^r$, and its rank is easily seen to be $(\text{rank } \mathcal{R}_T)^2 - \deg \lambda_T$.

This last quantity is zero if and only if rank $\mathcal{R}_T = 1$.

2 $\iff$ 3 is well known.
1 ⇒ 4. If $K_0(A_T)$ has no infinitesimals then $\alpha_*$ must be the identity on $K_0(A_T)$, since $\alpha_*(g)$ can only differ from $g$ by an infinitesimal.

4 ⇒ 2. The existence of infinitesimals implies that $T$ has an eigenvalue $\lambda$ with $0 < |\lambda| < \lambda_T$. We can find in the above representation of $K_0(A_T)$ a matrix $U$ with large entries such that $UT \approx \lambda U$ and $TU \approx \lambda_T U$, and then $\alpha_*(U) \approx \lambda^{-1} \lambda_T(U) \not\approx U$. $\square$

6 The Rohlin property for $\alpha_T$

**Theorem 6.1** If the matrix $T$ is primitive then $\alpha_T$ has the Rohlin property.

Fix a primitive matrix $T$. To simplify notation we drop the subscript $T$ from the various objects defined in the previous sections. Before proving the theorem we need some preliminary results.

**Lemma 6.2** For any $x, y \in A$

$$\|[[\alpha^n(x), y]]\| \to 0 \text{ as } |n| \to \infty.$$

**Proof.** Given $x$ and $y$ we can find an interval $I$ and elements $x', y' \in H^I_T$ such that $\|x - x'\|$ and $\|y - y'\|$ are as small as desired. If $n > |I|$ then $I \cap (I + n) = \emptyset$ and since $\alpha^n(x') \in H^{I+n}_T$ we see from Lemma 4.15 that $\alpha^n(x')$ commutes with $y'$. Thus

$$\|\alpha^n(x)y - y\alpha^n(x)\| \leq \|\alpha^n(x)y - \alpha^n(x')y\| + \|\alpha^n(x')y - \alpha^n(x'y')\|$$

$$+ \|\alpha^n(x'y') - y'\alpha^n(x')\| + \|y'\alpha^n(x') - y\alpha^n(x')\|$$

$$+ \|y\alpha^n(x') - y\alpha^n(x)\|$$

$$\leq \|x - x'\| \|y\| + \|x'\| \|y - y'\| + 0 + \|y' - y\| \|x'\| + \|y\| \|x' - x\|$$

$$\leq 2\|y\| \|x - x'\| + 2(\|x\| + \|x - x'\|) \|y - y'\|$$

for all $n > |I|$. By making $\|x - x'\|$ and $\|y - y'\|$ sufficiently small we can make this last quantity as small as desired for all sufficiently large $n$. $\square$

**Remark 6.3** Lemma 6.2 provides an immediate simplification of our situation. In proving the Rohlin property for $\alpha$ we may ignore the almost commuting requirements, since for any finite collection of projections and partial isometries satisfying all the other properties their images under $\alpha^n$, for sufficiently large $n$, have the additional property of almost commuting with the finite set $F$.

Our next lemma says that $\alpha_*$ has arbitrarily small non-infinitesimal fixed points.
Lemma 6.4 For every $n > 0$ there exists $g \in K_0(A)_+$ such that $\alpha_*(g) = g$ and $ng < [1]$.

Proof. For any interval $I = [a, b]$, $K_0(H^I)$ is isomorphic to a subspace of $M_r(\mathbb{Z})$ via the map that takes the class of a minimal projection $E_{u,a,b} \in H^I$ to the matrix having $(i(u), t(u))$th entry equal to one and all other entries equal to zero. With this identification the class of the unit in $K_0(H^I)$ is $[1]_I = T^{|I|+1}$.

Choose $m$ such that $nI < T^m$. Let $g \in K_0(A)$ be the element represented by the identity matrix $I$ in $K_0(H^{[0,m]})$. We claim that this $g$ is fixed by $\alpha_*$. Indeed, $g$ is represented by $TI$ in $K_0(H^{[0,m-1]})$ and thus by $IT$ in $K_0(H^{[0,m]})$. $\blacksquare$

Next we show that the fixed points of $\alpha_*$ are order-dense.

Lemma 6.5 For any $m \in \mathbb{N}$ there exists $g \in K_0(A)$ such that $\alpha_*(g) = g$ and $mg < [1] < (m+1)g$.

Proof. By Lemma 6.4 we can find $h \in K_0(A)_+$ fixed by $\sigma_*$ such that $m(m+1)h < [1]$. Let $N$ be the greatest positive integer for which $Nh < [1]$. While $(N+1)h$ may differ from $[1]$ by an infinitesimal we certainly have $(N+2)h > [1]$. Set $g = [N/m]h$. We obviously have $m[N/m] \leq N$. Write $N = \ell m + k$ with $0 \leq k \leq m-1$. Since $N \geq m(m+1)$ we must have $\ell \geq m+1$. Now

$$(m+1)[N/m] = (m+1)\ell = \ell m + (m+1) \geq \ell m + k + 2 = N + 2,$$

and thus $g$ has the desired properties. $\blacksquare$

Lemma 6.6 For any $m \in \mathbb{N}$ there exists a clopen subset $C$ of $X$ such that

1. $C, \sigma(C), \ldots, \sigma^{m-1}(C)$ are pairwise disjoint,
2. $1 - m[\varphi(\chi_C)] < [\varphi(\chi_C)]$, and
3. $\alpha_*([\varphi(\chi_C)]) = [\varphi(\chi_C)]$.

Proof. Fix $m$ and let $g$ be as in Lemma 6.5. By Lemma 4.12 we can find $\varepsilon > 0$ such that if $U$ is any clopen set in $X$ with $\mu U < \varepsilon$ then $[\varphi(\chi_U)] < [1] - mg$. Let $x$ be a finite path in $G$ long enough so that

$$\mu \left( \bigcup_{k=1}^{m-1} \text{cyl}(x, -k) \right) < \varepsilon/2.$$

We can find $N \in \mathbb{N}$ large enough so that

$$\mu \left( \bigcup_{k=0}^{Nm-1} \text{cyl}(x, k) \right) > 1 - \varepsilon/2.$$
Let \( C' \) be the set of points \( y \in \bigcup_{k=0}^{Nm-1} \text{cyl}(x,k) \) for which the least \( k \geq 0 \) such that \( y \in \text{cyl}(x,k) \) satisfies \( k \equiv m-1 \mod m \). The sets \( \sigma^k(C') \), \( 0 \leq k \leq m-1 \) are pairwise disjoint and
\[
\left( \bigcup_{k=0}^{Nm-1} \text{cyl}(x,k) \right) \setminus \left( \bigcup_{k=1}^{m-1} \text{cyl}(x,-k) \right) \subset \bigcup_{k=0}^{m-1} \sigma^k(C')
\]
whence
\[
\mu \left( X \setminus \left( \bigcup_{k=0}^{m-1} \sigma^k(C') \right) \right) < \varepsilon.
\]
This implies that \([\varphi(\chi_{C'})] > g\).

By Lemma 2.7, \([\varphi(\chi_{C'})] - g\) is the class of some projection \( e \in A_T \) and by Lemma 2.9, \( e \) is equivalent to some projection \( f < \varphi(\chi_{C'}) \). Every projection in \( A \) is equivalent to one of the form \( \varphi(\chi_E) \) for some clopen set \( E \) (this is just the statement that every projection in a finite direct sum of full matrix algebras is equivalent to a diagonal matrix), so we can find a set \( E \) such that \([\varphi(\chi_E)] = [f]\), and because \( f < \varphi(\chi_{C'}) \) we can take \( E \) to be a subset of \( C' \). Set \( C = C' \setminus E \). Then \([\varphi(\chi_C)] = g\) and properties (1)–(3) are satisfied. \( \square \)

**Proof of Theorem 6.1.** Given \( m \in \mathbb{N}, \varepsilon > 0 \), and a finite subset \( F \) of \( A \) we let \( C \) be as in Lemma 6.6 and set \( e_i = \varphi(\chi_C) \). By Remark 6.3, we need not consider \( F \) at all. Our construction guarantees the \( [e_i] \) are all the same, and that \([1 - \sum_i e_i] < [e_0]\), so the partial isometries needed to apply Theorem 3.4 exist. \( \square \)

**Proposition 6.7** If \( T_1 \) and \( T_2 \) are shift equivalent primitive integral matrices then \( A_{T_1} \times_{\alpha_{T_2}} \mathbb{Z} \cong A_{T_2} \times_{\alpha_{T_2}} \mathbb{Z} \).

**Proof.** Let us write \( \alpha_i \) for \( \alpha_{T_i} \) and \( A_i \) for \( A_{T_i}, \ i = 1, 2 \). Shift equivalence implies that there is an isomorphism \( \rho : A_1 \cong A_2 \) such that
\[
\rho_* \circ (\alpha_1)_* = (\alpha_2)_* \circ \rho_*
\]
and
\[
\rho_* (K_0(A_1)_+) = K_0(A_2)_+.
\]
By Theorem 4.1 of [6], there is an automorphism \( \beta \) of \( A_2 \) and a unitary \( u \in A_2 \) such that
\[
\alpha_1 = \rho^{-1} \circ \text{Ad} u \circ \beta \circ \alpha_2 \circ \beta^{-1} \circ \rho.
\]
For \( i = 1, 2 \), the crossed product \( A_i \times_{\alpha_i} \mathbb{Z} \) is generated by \( A_i \) and a unitary \( v_i \) such that
\[
v_ia = \alpha_i(a)v_i.
\]
Define \( \Phi : A_1 \times_{\alpha_1} \mathbb{Z} \to A_2 \times_{\alpha_2} \mathbb{Z} \) by setting
\[
\Phi(v_1) = \beta^{-1}(u)v_2.
\]
\( \Phi(a) = \beta^{-1}(\rho(a)), \ a \in A_1. \)

The map \( \Phi \) is a well-defined \(*\)-homomorphism because

\[
\Phi(v_1 a) = \beta^{-1}(u)v_2\beta^{-1}(\rho(a)) \\
= \beta^{-1}(u)(\alpha_2 \circ \beta^{-1} \circ \rho)(a)v_2 \\
= \beta^{-1}(u(\beta \circ \alpha_2 \circ \beta^{-1} \circ \rho)(a)u^*u)v_2 \\
= (\beta^{-1} \circ \rho \circ \alpha_1)(a)\beta^{-1}(u)v_2 \\
= \Phi(\alpha_1(a)v_1).
\]

To see that it is invertible observe that \( \beta^{-1} \circ \rho \) is an isomorphism and

\[
\Phi(\rho^{-1}(u^*)v_1) = \beta^{-1}(\rho(\rho^{-1}(u^*)))\beta^{-1}(u)v_2 = \beta^{-1}(u^*u)v_2 = v_2.
\]

\( \square \)

**Remark 6.8** We do not know whether isomorphism of the crossed product algebras implies shift equivalence, or whether \( (A_{T_1}, \alpha_{T_1}) \cong (A_{T_2}, \alpha_{T_2}) \) is equivalent to shift equivalence, strong shift equivalence, or neither.

**Acknowledgements**

This work was part of my doctoral thesis. I thank my advisor, Jack Wagoner, for mentorship and guidance. I am grateful to Nate Brown, who introduced me to the Rohlin property for automorphisms of \( C^* \)-algebras. I also thank Kenley Jung and Ian Putnam for helpful discussions.
