Diagnostic exome sequencing (DES) is a powerful tool to analyze the pathogenic variants leading to development delay (DD) and intellectual disability (ID). Recently, heterozygous \textit{de novo} mutation of the histone acetyltransferase encoding gene \textit{KAT6B} has been recognized as causing a syndrome with congenital anomalies and intellectual disability, namely Say-Barber-Biesecker-Young-Simpson (SBBYS) syndrome. Here we report a case of SBBYS syndrome in a third generation Korean family affected with a missense mutation in \textit{KAT6B}, c.2292C>T p.(His767Tyr) identified by DES. This is the first confirmed familial inherited mutation of the \textit{KAT6B} reported worldwide. Our case emphasizes again the importance of basic physical examination and taking a family history. Furthermore, advances in genetic diagnostic tools are becoming key to identifying the etiology of DD and ID. This allows a physiatrist to predict the disease’s clinical evolution with relative certainty, and offer an appropriate rehabilitation plan for patients.

\textbf{Keywords} Say-Barber-Biesecker-Young-Simpson variant of Ohdo syndrome, Intellectual disability, \textit{KAT6B} protein

\section*{INTRODUCTION}

Developmental delay (DD) and intellectual disability (ID) are major neuropsychological disorders in children, affecting 1\%–3\% of the general population. Of DD/ID cases, 17.4\%–47.1\% can be explained by genetic factors [1]. Recently, diagnostic exome sequencing (DES) has been introduced to analyze the underlying cause of unexplained DD/ID with the discovery of a novel disease
gene. Heterozygous de novo mutation of the histone acetyltransferase encoding gene KAT6B has been recognized to cause a syndrome with congenital anomalies and intellectual disability, namely Say-Barber-Biesecker-Young-Simpson syndrome (SBBYSS) [2].

Here, we present a case of SBBYSS in three generations of a Korean family affected with a missense mutation in KAT6B, c.2292C>T p.(His767Tyr) identified by DES. This is the first inherited KAT6B missense mutation reported worldwide.

CASE REPORT

The 3-year-old girl visited the department of rehabilitation medicine for evaluation due to developmental delay. She was the first born child of unrelated nonconsanguineous parents. At birth, mother and father were 23 and 30 years old, respectively. She was born in the 40th week of gestation after an uncomplicated pregnancy. Her birth weight was 3,500 g (50th–75th percentile). At the age 2, bilateral blepharophimosis and strabismus were noticed during an ophthalmologic evaluation. She sat at 10 months and walked at 18 months. Speech development was also slightly delayed. She started to say few simple words at 2 years, and was able to make phrases with 2–3 words at 3 years. Her social and emotional development declined, and she was described as shy, having little interaction with other people. On physical examination at the age of 3, her height was 90 cm (25th–50th percentile), weight 12 kg (below 25th percentile) and her occipital-frontal circumference was 46 cm (below 3rd percentile). She had an immobile face, blepharophimosis, ptosis, a broad and flat nasal bridge, and a low set of large protruding ears (Fig. 1). Further investigations, routine laboratory tests (including thyroid function tests, brain magnetic resonance imaging, electroencephalogram and joint X-rays) did not reveal any abnormality. During the examination, we noticed that her father also had a

Fig. 1. Facial features of the proband (A), father (B, C), grandmother (D), uncle (E, F), and contracture deformity in metacarpophalangeal joints of father (G).
similar dysmorphic face. He had a contracture deformity in his metacarpophalangeal joints that prevented him from making a tight fist (Fig. 1). He had graduated from college and was working in a manufacturing job as a simple laborer. According to the Korean–Wechsler Adult Intelligence Scale-IV, his intellectual quotient was 66, indicating intellectual disability. The pedigree acquired from the patient revealed that the patient’s uncle was also diagnosed as moderately mentally retarded. Also, her deceased grandmother who was severely mentally retarded (Fig. 2). Given the family history, we arranged a chromosomal microarray for the patient that yielded a normal result. DES was performed on the subject, followed by Sanger sequencing of the family trio (proband and both parents), identified KAT6B missense mutation in c.2292C>T p.(His767Tyr) in the patient and her father. To better understand the relationship between the KAT6B variant and the familiar inheritance pattern, additional familial testing included the grandfather and uncle. The uncle was found to carry the same KAT6B variant (Fig. 3). Considering these results and family history, the patient’s grandmother was deemed an obligatory heterozygote. The variant was predicted to be deleterious in silico analysis using Sorting Intolerant from Tolerant (SIFT) with a score of 0.01 (resulting as damaging), Polymorphism Phenotyping v2 (PolyPhen-2) with a score of 0.87 (resulting as possibly damaging), and MutationTaster resulting as disease causing (prob: 0.999999996930964).

They were diagnosed as SBBYSS. Although a few cases with KAT6B have been reported worldwide, this is the first confirmed family inherited mutation of the KAT6B variant to date.

**DISCUSSION**

SBBYSS is a very rare syndrome associated with the KAT6B mutation. Clinical findings include a distinctive facial appearance with severe blepharophimosis, an immobile mask-like face, a bulbous nasal tip, and a small mouth with a thin upper lip, usually accompanied by

\(^b\) Percentages in the parenthesis indicate percentage with the addition of patients in whom the symptoms were not reported to be present or absent in previously reported cases.
In this report, DES was crucial for a correct diagnosis. DES has proven to be a powerful tool with a 25% diagnostic yield for the identification of pathogenic variants leading to Mendelian disorders in DD and ID [10]. DES can detect single-nucleotide substitutions, and insertions or deletions, of 8 to 10 nucleotides or smaller. It is suggested that DES, together with array-based comparative genomic hybridization array, is a first-tier diagnostic tool to evaluate unexplained DD and ID. Patients with DD and ID often undergo a lengthy, time-consuming process for a definitive diagnosis, commonly known as a ‘diagnostic odyssey’. Establishing an exact diagnosis in patients with DD and ID is important because it brings comfort to the patient’s family, enables prediction of the disease’s clinical course with relative certainty, allows formulation of an appropriate rehabilitation plan, and maintains general health. It also assists in accurately determining the risk of recurrence in subsequent pregnancies. Physiatrists are likely to be the first to encounter these patients. Therefore, to ensure a correct diagnosis, a careful physical examination that gathers detailed information on family history, and an appropriate genetic analysis, should be considered for patients with unexplained DD or ID.

To the best of our knowledge, this is the first molecular genetic analysis of a SBBYSS patient from the Korean population, and the first three generation inherited KAT6B missense mutation seen worldwide. This report broadens the phenotypic spectrum. Furthermore, the possibility of gonadal mosaicism must be considered to explain the rare familial recurrence of this condition. We also showed that DES can be useful tool to identify causative pathogenic variants in patients with DD and ID.

CONFLICT OF INTEREST

No potential conflict of interest relevant to this article was reported.

ACKNOWLEDGMENTS

We thank the family of the patient for their participation in the study. The genetic analysis in this study was funded by Korean Foundation for Rare Disease.
