Abstract: This paper presents necessary and sufficient conditions for the existence of a real root of maximal multiplicity in the spectrum of a linear time-invariant single-delay equation of retarded type. We also prove that this root is always strictly dominant, and hence determines the asymptotic behavior of the system. These results are based on improved a priori bounds on the imaginary part of roots on the complex right half-plane.

Keywords: Time-delay equations, stability analysis, spectral methods, root assignment.

1. INTRODUCTION

Systems with time delays are useful models in a wide range of scientific and technological domains such as biology, chemistry, economics, physics, or engineering, the presence of the delays usually coming from propagation phenomena, such as of material, energy, or information, with a finite propagation speed. Due to their numerous applications, these kinds of systems have been the subject of much attention by researchers in several fields, in particular since the 1950s and 1960s. We refer to Gu et al. (2003); Hale and Verduyn Lunel (1993); Michiels and Niculescu (2014) for details on time-delay systems and their applications.

In this paper, we consider linear time-invariant equations with a single delay of the form

\[
y^{(n)}(t) + a_{n-1}y^{(n-1)}(t) + \cdots + a_0 y(t) + a_{n-1}y^{(n-1)}(t-\tau) + \cdots + a_0 y(t-\tau) = 0,
\]

where \( n \) is a positive integer, the coefficients \( a_k \) are real numbers for \( k \in \{0,\ldots,n-1\} \), and the delay \( \tau \) is a positive real number. Equation (1) is said to be of retarded type since the derivative of highest order only appears in the non-delayed term \( y^{(n)}(t) \).

The stability analysis of equations of the form (1) and more general time-delay systems has attracted much research effort and is an active field (see, e.g., Chen et al. (1995); Gu et al. (2003); Hale and Verduyn Lunel (1993); Michiels and Niculescu (2014); Olgaç and Sipahi (2002); Sipahi et al. (2011); Li et al. (2017)). In the delay-free situation, i.e., when \( a_k = 0 \) for every \( k \in \{0,\ldots,n-1\} \), the stability of (1) can be studied through spectral methods by considering the corresponding characteristic polynomial, whose complex roots determine the asymptotic behavior of solutions of the system. Under the presence of delays, the asymptotic behavior of (1) is also determined by the complex roots of some characteristic function \( \Delta : \mathbb{C} \to \mathbb{C} \) (see, e.g., Hale and Verduyn Lunel (1993); Michiels and Niculescu (2014); Mori et al. (1982)), defined for \( s \in \mathbb{C} \) by

\[
\Delta(s) = s^n + \sum_{k=0}^{n-1} a_k s^k + e^{-s\tau} \sum_{k=0}^{n-1} a_k s^k.
\]

Functions of the form (2) are particular instances of quasipolynomials, defined as follows (see, e.g., Wielonsky (2001); Berenstein and Gay (1995)).

Definition 1. A quasipolynomial is an entire function \( Q \) which can be written under the form

\[
Q \left( s; \lambda_0, (a_j)_{j=0}^{d_0}, \ldots, \lambda_\ell, (a_{j\ell})_{j=0}^{d_\ell} \right) = \sum_{k=0}^\ell p_k(s)e^{-\lambda_ks},
\]

where \( \ell \) is a positive integer, \( \lambda_0, \ldots, \lambda_\ell \) are pairwise distinct real numbers, and, for \( k \in \{0,\ldots,\ell\} \), \( a_{dk} \neq 0 \) and \( p_k \) is the polynomial \( p_k(s) = \sum_{j=0}^{d_k} a_{j,k}s^j \) of degree \( d_k \). The integer \( D = \ell + \sum_{k=0}^\ell d_k \) is called the degree of \( Q \).

When \( \lambda_0 = 0 \) and \( \lambda_1, \ldots, \lambda_\ell \) are positive, the above general quasipolynomial is the characteristic equation of a linear time-invariant delayed equation with delays \( \lambda_1, \ldots, \lambda_\ell \). A classical result on quasipolynomials provided in (Pólya and Szegő, 1998, Problem 206.2) (which holds independently on the sign of \( \lambda_k \), known as the Pólya-Szegő bound, implies that, given a quasipolynomial \( Q \) of degree \( D \geq 0 \), the multiplicity of any root of \( Q \) does not exceed \( D \). For the quasipolynomial \( \Delta \) from (2), this means that any
of its roots has multiplicity at most $2n$. Recent works such as Boussaada and Niculescu (2016a,b) have provided characterizations of multiple roots of quasipolynomials using approaches based on Birkhoff and Vandermonde matrices.

Similarly to the delay-free case, the quasipolynomial $\Delta$ is useful for the stability analysis of (1). Indeed, all solutions of (1) converge exponentially fast to 0 if and only if $\Re s < 0$ for every $s \in \mathbb{C}$ such that $\Delta(s) = 0$, and the asymptotic behavior of solutions of (1) is determined by the real number $\gamma_0 = \sup\{\Re s \mid s \in \mathbb{C}, \Delta(s) = 0\}$, called the spectral abscissa of $\Delta$. However, contrarily to the delay-free case, (2) has infinitely many roots. Designing a general criterion in terms of the coefficients $a_k, \alpha_k$ for $k \in \{0, \ldots, n-1\}$ and the delay $\tau$ ensuring that all roots of $\Delta$ have negative real part is a difficult problem (see Hayes (1950) for some early results in the case $n = 1$), which is in contrast with the delay-free case in which Routh–Hurwitz criterion provides a stability test in terms of the coefficients of the characteristic polynomial.

The spectral abscissa of $\Delta$ is related to the notion of dominant root, defined as follows.

**Definition 2.** Let $Q : \mathbb{C} \to \mathbb{C}$ and $s_0 \in \mathbb{C}$ be such that $Q(s_0) = 0$. We say that $s_0$ is a dominant (respectively, strictly dominant) root of $Q$ if, for every $s \in \mathbb{C} \setminus \{s_0\}$ such that $Q(s) = 0$, one has $\Re s \leq \Re s_0$ (respectively, $\Re s < \Re s_0$).

Dominant roots may not exist for a given function of a complex variable, but they always exist for functions of the form (2), as a consequence, for instance, of the fact that $\Delta$ has finitely many roots on any vertical strip in the complex plane (see, e.g., (Hale and Verduyn Lunel, 1993, Chapter 1, Lemma 4.1)). Notice also that exponential stability of $\Delta$ is equivalent to the dominant root of $\Delta$ having negative real part.

It turns out that, for quasipolynomials, the notions of real roots of high multiplicity and dominance are often related (see, e.g., Boussaada and Niculescu (2016b); Boussaada et al. (2020, 2018)), in the sense that real roots of high multiplicity tend to be dominant, a property usually referred to as multiplicity-induced dominance (MID for short). MID has been shown to hold, for instance, in the case $n = 2$ and $\alpha_1 = 0$ in Boussaada et al. (2018), proving dominance thanks to a suitable factorization of $\Delta$ when it admits a root of multiplicity 3; and in the case $n = 2$ and $\alpha_1 \neq 0$ in Boussaada et al. (2020), using Cauchy’s argument principle to prove dominance of the multiple root.

Another motivation for considering roots of high multiplicity is the fact that, for delay-free systems with an affine constraint on their coefficients, the spectral abscissa is minimized on a polynomial with a single root of maximal multiplicity (see Blondel et al. (2012); Chen (1979)). Similar properties of spectral abscissa minimization on multiple roots have also been observed for some time-delay systems in Michiels et al. (2002); Ramirez et al. (2016); Vanbiervliet et al. (2008). Hence, the interest in investigating multiple roots does not rely on the multiplicity itself, but rather on its connection with the dominance of this root, and the corresponding applications in stability analysis and control design.

The main goal of this paper is to investigate whether MID holds for the quasipolynomial $\Delta$ from (2) when assigning a root with maximal multiplicity. More precisely, the questions we address in this paper are the following.

**(Q1)** Is it possible to choose $a_0, \ldots, a_{n-1}, a_0, \ldots, a_n \in \mathbb{R}$ in such a way that a given real number $s_0$ is a root of maximal multiplicity $2n$ of $\Delta$?

**(Q2)** Under the above choice, is $s_0$ (strictly) dominant?

Our main result, Theorem 7, provides affirmative answers to both questions. Question (Q1) can be addressed in a straightforward manner, whereas the answer to (Q2) relies on a sharp a priori bound on the imaginary part of roots of $\Delta$ with nonnegative real part, established in Lemma 5.

The paper is organized as follows. Notations used in the paper are standard. Section 2 provides a detailed study of (1) and (2) in the case $n = 2$, its main result being necessary and sufficient conditions for the existence of a root of maximal multiplicity and the proof of strict dominance of this root. Notice that this case has already been considered in Boussaada et al. (2020), but using a different strategy for addressing (Q2), based on an application of Cauchy’s argument principle to a suitable contour. As it will be clear below, our approach allows for a simpler and easier dominance proof. Our main result is presented in Section 3, which extends the analysis of Section 2 to any positive integer $n$. For the brevity of the paper, the full proof is not provided here, but it can be obtained by the same arguments as those provided in Section 2 and will be presented in details in an extended version of this paper. Finally, Section 4 presents an example illustrating our main result.

**2. MOTIVATING EXAMPLE: SECOND-ORDER CASE**

Consider (2) with $n = 2$, i.e.,

$$\Delta(s) = s^2 + a_1 s + a_0 + e^{-\tau s} (a_1 s + a_0)$$

and recall that the degree of $\Delta$ is at most 4. The main result we will prove concerning this quasipolynomial is the following.

**Theorem 3.** Consider the quasipolynomial $\Delta$ given by (3) and let $s_0 \in \mathbb{R}$.

(a) The number $s_0$ is a root of multiplicity 4 of $\Delta$ if and only if the coefficients $a_0, a_1, a_0, a_1$, the root $s_0$ and the delay $\tau$ satisfy the relations

$$a_1 = -\frac{4}{\tau} - 2s_0, \quad a_0 = \frac{6}{\tau^2} + \frac{4}{\tau} s_0 + s_0^2, \quad (4a)$$

$$a_1 = -\frac{2e^{\gamma_0 \tau}}{\tau}, \quad a_0 = \frac{2}{\tau} e^{\gamma_0 \tau} \left( s_0 - \frac{3}{\tau} \right). \quad (4b)$$

(b) If (4) is satisfied, then $s_0$ is a strictly dominant root of $\Delta$.

**Remark 4.** The expressions of $a_1, a_0, a_1, a_0$ in (4) are singular with respect to $\tau$ as $\tau \to 0$. If one is interested in studying the behavior of the roots of $\Delta$ as $\tau \to 0$ when (4) is satisfied, one may consider instead the quasipolynomial

$$s \mapsto \tau^2 \Delta(s),$$

which has the same roots as $\Delta$ but whose coefficients are regular with respect to $\tau$.

Notice that, up to a translation and a scaling of the spectrum represented by the change of variables $z = \tau (s - \alpha_1)$.
which implies that

\[ a_1 = -4, \quad a_0 = 6, \quad \alpha_1 = -2, \quad \alpha_0 = -6, \]

yielding the quasipolynomial

\[ \hat{\Delta}(z) = z^2 - 4z + 6 - e^{-\tau}(2z + 6). \tag{5} \]

An important ingredient for the proof of (3) is the following result, which provides an a priori bound on the imaginary part of the roots of \( \hat{\Delta} \) on the closed right half-plane.

**Lemma 5.** Let \( z_0 \) be a root of \( \hat{\Delta} \) with \( \Re z_0 \geq 0 \). Then \( |\Im z_0| < 2\pi \).

**Proof.** Let \( \sigma = \Re z_0, \omega = \Im z_0 \), and

\[ A_0 = \begin{pmatrix} 0 & 1 \\ -6 & 4 \end{pmatrix}, \quad A_1 = \begin{pmatrix} 0 & 0 \\ 6 & 2 \end{pmatrix}. \tag{6} \]

Notice that \( \hat{\Delta}(z) = \det(z \mathbf{I} - A_0 - A_1 e^{-z}) \) for every \( z \in \mathbb{C} \). Hence the root \( z_0 \) of \( \hat{\Delta} \) is an eigenvalue of the matrix \( A_0 + A_1 e^{-z_0} \), and thus \( |z_0| \leq \rho(A_0 + A_1 e^{-z_0}) \). Since, by Gelfand’s formula, one has \( \rho(M) = \inf_{\|M^n\|^{1/n}} \) for every square matrix \( M \) and every submultiplicative norm \( \|\cdot\| \), one obtains in particular that

\[ \omega^4 \leq \|(A_0 + A_1 e^{-z_0})^2\|^2, \tag{7} \]

where \( \|\cdot\|_2 \) denotes the Frobenius norm. Then

\[
\omega^4 \leq 36|e^{-\omega_0} - 1|^2 + 4|e^{-\omega_0} + 2|^2 + 144|e^{-\omega_0} - 1|^2|e^{-\omega_0} + 2|^2 + (|2e^{-\omega_0} + 4|^2 + 6e^{-\omega_0} - 6)^2,
\]

from where we obtain that

\[ 0 \leq -992e^{-2\sigma} \cos^2 \omega + (464e^{-2\sigma} - 192)e^{-\sigma} \cos \omega + 728 + 1164e^{-2\sigma} + 160e^{-4\sigma} - \omega^4. \tag{8} \]

The right-hand side of the above inequality can be seen as a real polynomial of degree 2 in the variable \( e^{-\sigma} \cos \omega \) with negative leading coefficient, and hence the above inequality is satisfied only if the discriminant of the corresponding second-degree polynomial is non-negative, i.e.,

\[ (464e^{-2\sigma} - 192)^2 + 3968(728 + 1164e^{-2\sigma} + 160e^{-4\sigma} - \omega^4) \geq 0, \]

which implies that

\[ \omega^4 \leq 728 + 1164e^{-2\sigma} + 160e^{-4\sigma} + \frac{(464e^{-2\sigma} - 192)^2}{3968}, \]

and, since \( \sigma \geq 0 \), we obtain the bound

\[ |\omega| \leq \sqrt{\frac{64190}{31}} < 6.75. \]

Assume, to obtain a contradiction, that \( 2\pi \leq |\omega| < 6.75 \). Then \( \cos \omega \in (0, 0.893, 1) \) and, using further that \( |464e^{-2\sigma} - 192| \leq 272 \) and \( e^{-\sigma} \leq 1 \), it follows from (8) that \( |\omega| \leq \sqrt{1532.94} < 2\pi \), yielding the required contradiction. Hence \( |\omega| < 2\pi \).

**Remark 6.** The inequality

\[ |z_0| \leq \rho(A_0 + A_1 e^{-z_0}) \tag{9} \]

on roots \( z_0 \) of \( \hat{\Delta} \) used in the proof of Lemma 5 is a classical inequality for time-delay systems of retarded type (see, e.g., (Michiels and Niculescu, 2014, Proposition 1.10)). However, manipulating and extracting information directly from this inequality is usually a difficult task since it involves the computation of the spectral radius of \( A_0 + A_1 e^{-z_0} \) as a function of \( z_0 \). Several works use instead the fact that the spectral radius is a lower bound on any submultiplicative matrix norm \( \|\cdot\| \) and consider, instead of (9), the coarser inequality

\[ |z_0| \leq \|A_0 + A_1 e^{-z_0}\|, \tag{10} \]

choosing typically easier-to-compute norms, such as the 1 norm, the Frobenius norm, or the \( \infty \) norm. However, (10) is usually much coarser than (9). As an illustration, Table 1 provide numerical values for the best bounds on \( |\Im z_0| \) that one may have using (9) and (10) for \( z_0 \in \mathbb{C} \) with \( \Re z_0 \geq 0 \).

| Inequality | Numerical bound on \( |\Im z_0| \) |
|------------|-----------------|
| (9)        | 5.9763          |
| (10) with the 1 norm | 10.4520  |
| (10) with the Frobenius norm | 10.6304  |
| (10) with the \( \infty \) norm | 11.4729  |

It follows from the analysis of Table 1 that it is not possible to obtain the conclusion of Lemma 5 only from (10) with the above choices of norms. This is what motivates the strategy used in the proof of Lemma 5, which relies on Gelfand’s formula for the spectral radius to obtain from (9) the inequalities

\[ |z_0|^n \leq \|(A_0 + A_1 e^{-z_0})^n\|, \tag{11} \]

for any submultiplicative norm \( \|\cdot\| \) and any \( n \in \mathbb{N} \). For \( n = 1 \), (11) reduces to (10) but, for larger \( n \), (11), while still coarser than (9), is usually sharper than (10) (even though this may not always be the case; see, e.g., (Kato, 1995, Chapter 1, Remark 4.2)). We represent in Figure 1 the boundary of the sets of \( z_0 \in \mathbb{C} \) satisfying inequality (9) involving the spectral radius (solid line) and inequality (11) with \( n = 2 \) for the 1, Frobenius, and \( \infty \) norms (dashed, dotted, and dash-dotted lines), using the matrices \( A_0 \) and \( A_1 \) from (6). The sets themselves are on the left-hand side of the represented boundaries. We also represent, in Table 2, numerical bounds on \( |\Im z_0| \) obtained using (11) with \( n = 2 \) and same choices of norms as before.

| Inequality | Numerical bound on \( |\Im z_0| \) |
|------------|-----------------|
| (11) with the 1 norm | 6.4630  |
| (11) with the Frobenius norm | 6.8053  |
| (11) with the \( \infty \) norm | 7.8163  |

Comparing Table 1 with Table 2, one verifies that the bounds obtained from (11) with \( n = 2 \) are sharper than the ones from (10), and (11) with \( n = 2 \) and the Frobenius norm is sufficient to prove Lemma 5, justifying the strategy of our proof.

In addition to the above strategies based on (9) and inequalities between the spectral radius and matrix norms, there are also other techniques to obtain a priori bounds on roots of quasipolynomials of the form (2), such as those used in Mori and Kokame (1989) and their improved versions in Wang (1992) and Tissir and Hrma (1996).
As a consequence of the bound by T. Mori and H. Kokame, one obtains that, if \( z_0 \in \mathbb{C} \) is a root of \( \Delta \) with nonnegative real part, then
\[
|\text{Im} \, z_0| \leq \mu(-iA_0) + \|A_1\|,
\]
where \( \|\cdot\| \) denotes a matrix norm induced by a vector norm and \( \mu \) is defined for a square matrix \( M \) by \( \mu(M) = \lim_{\epsilon \to 0} \frac{1}{\epsilon} \| (\text{Id} + \epsilon M) \| - 1 \). The improved bound by E. Tissir and A. Hmamed implies that
\[
|\text{Im} \, z_0| \leq \mu(-iA_0) + \max_{0 \leq \theta \leq 2\pi} \mu(A_1 e^{i\theta}).
\]
Numerical values of these bounds with \( A_0 \) and \( A_1 \) given by (6) and using the 1, 2, and \( \infty \) norms are presented in Table 3 (note that one can no longer use the Frobenius norm since it is not induced by any vector norm). We remark that none of these bounds can be used to obtain the conclusion of Lemma 5.

Table 3. Bounds on \( |\text{Im} \, z_0| \) obtained from (12) and (13) with three different choices of norms

| Inequality | Bound on \( |\text{Im} \, z_0| \) |
|------------|-------------------------------|
| (12) with the 1 norm | 12 |
| (12) with the 2 norm | 9.8246 |
| (12) with the \( \infty \) norm | 14 |
| (13) with the 1 norm | 12 |
| (13) with the 2 norm | 7.6623 |
| (13) with the \( \infty \) norm | 14 |

The above a priori bounds are far from forming an exhaustive list. Obtaining sharper bounds is an active research topic with important practical implications (see, e.g., Cardeliquio et al. (2020) for recent developments on this topic).

**Proof of Theorem 3.** Let us denote by \( \tilde{\Delta} \) the quasipolynomial obtained by multiplying \( \Delta \) by \( \tau^2 \) and performing the change of variables \( z = \tau(s - s_0) \), i.e.,
\[
\tilde{\Delta}(z) = \tau^2 \Delta(s_0 + \frac{z}{\tau}) = z^2 + b_1 z + b_0 + e^{-\tau}(\beta_1 z + \beta_0),
\]
where
\[
b_1 = (a_1 + 2 s_0) \tau, \quad b_0 = (s_0^2 + a_1 s_0 + a_0) \tau^2, \quad \beta_1 = a_1 \tau e^{-s_0 \tau}, \quad \beta_0 = (a_0 + a_1 s_0) \tau^2 e^{-s_0 \tau}.
\]
Note that \( s_0 \) is a root of multiplicity 4 of \( \Delta \) if and only if 0 is a root of multiplicity 4 of \( \tilde{\Delta} \). Recalling that the degree of the quasipolynomial \( \tilde{\Delta} \) is 4, 0 is a root of multiplicity 4 if and only if \( \tilde{\Delta}^{(k)}(0) = 0 \) for \( k \in \{0, 1, 2, 3\} \). We compute
\[
\tilde{\Delta}'(z) = 2z + b_1 + e^{-\tau}(-\beta_1 z - \beta_0 + \beta_1),
\]
\[
\tilde{\Delta}''(z) = 2 + e^{-\tau}(\beta_1 z + \beta_0 - 2 \beta_1),
\]
\[
\tilde{\Delta}'''(z) = e^{-\tau}(-\beta_1 z - \beta_0 + 3 \beta_1),
\]
and one then obtains that 0 is a root of multiplicity 4 of \( \tilde{\Delta} \) if and only if
\[
b_0 + \beta_0 = 0, \quad b_1 - \beta_0 + \beta_1 = 0, \quad \beta_0 - 2 \beta_1 = -2, \quad -\beta_0 + 3 \beta_1 = 0.
\]
The unique solution of the above system is given by \( b_1 = -4, b_0 = 6, \beta_1 = -2, \) and \( \beta_0 = -6 \). Using (15), one immediately verifies that these conditions are equivalent to (4), concluding the proof of (a). Moreover, under these conditions, one has \( \tilde{\Delta} = \Delta \), where \( \Delta \) is defined in (5).

To prove (b), note that \( \tilde{\Delta} \) can be written as
\[
\tilde{\Delta}(z) = z^4 \int_0^1 t(t-1)^2 e^{-\tau t} dt,
\]
as one immediately verifies integrating by parts. Let \( s \) be a root of \( \Delta \) with \( s \neq s_0 \). Then \( z = \tau(s - s_0) \) is a root of \( \tilde{\Delta} \) with \( z \neq 0 \), and thus
\[
\int_0^1 t(t-1)^2 e^{-\sigma t} \cos(\omega t) \, dt = 0,
\]
\[
\int_0^1 t(t-1)^2 e^{-\sigma t} \sin(\omega t) \, dt = 0,
\]
where \( \sigma = \text{Re} \, z \) and \( \omega = \text{Im} \, z \). Since \( \tilde{\Delta} \) is a quasipolynomial with real coefficients, one may assume with no loss of generality that \( \omega \geq 0 \).
We have $\omega > 0$, since, if $\omega = 0$, then (17) is in contradiction with the fact that $t \mapsto t(t-1)^2e^{-\sigma t}$ is strictly positive in $(0,1)$. We also have $\omega > \pi$, since, if $\omega \leq \pi$, then $t \mapsto t(t-1)^2e^{-\sigma t}\sin(\omega t)$ is strictly positive in $(0,1)$. Assume, to obtain a contradiction, that $\sigma > 0$. Then, by Lemma 5, we obtain that $\pi < \omega < 2\pi$. By performing a suitable linear combination of (17) and (18), we have

$$\int_0^1 t(t-1)^2e^{-\sigma t}\sin\left(\omega \left(\frac{t}{2}\right)\right) dt = 0.$$  

Decomposing this integral in the intervals $(0, \frac{1}{2})$ and $(\frac{1}{2}, 1)$ and performing the changes of variables $t = \frac{1}{2} - \tau$ and $\tau = t - \frac{1}{2}$ in these intervals, respectively, we obtain

$$\int_0^{\frac{1}{2}} (\frac{1}{4} - \tau^2) \sin(\omega t) \sinh(\sigma t) dt = 0,$$

where sinh and cosh denote hyperbolic sine and cosine, respectively. Since $\pi < \omega < 2\pi$ and $\sigma > 0$, the function $t \mapsto (\frac{1}{4} - \tau^2) \sin(\omega t) \sinh(\sigma t)$ is strictly positive in $(0, \frac{1}{2})$, contradicting the above equality and thus concluding the proof of (b).

3. MAIN RESULT

The main result of the paper is the following theorem providing conditions for the maximal multiplicity of a root of $\Delta$ and establishing the dominance of this root. Recall that the maximal multiplicity of any root of $\Delta$ is $2n$.

**Theorem 7.** Consider the quasipolynomial $\Delta$ given by (2) and let $s_0 \in \mathbb{R}$.

(a) The number $s_0$ is a root of multiplicity $2n$ of $\Delta$ if and only if, for every $k \in \{0, \ldots, n-1\}$,

$$a_k = \begin{cases} \binom{n}{k} (-s_0)^{n-k} \\ + (-1)^{n-k} n! \sum_{j=k}^{n-1} \binom{j}{k} \binom{2n-j-1}{n-1} \frac{s_0^{j-k}}{j! \tau^{n-j}}. \end{cases}$$

$$a_k = (-1)^{n-k} e^{s_0 t} \sum_{j=k}^{n-1} \frac{(-1)^{j-k}(2n-j+1)!}{k!(j-k)!(n-j+1)!} s_0^{j-k} \pi^{n-j}. \quad (19)$$

(b) If (19) is satisfied, then $s_0$ is a strictly dominant root of $\Delta$.

By considering the first equation in (19) with $k = n-1$, one also obtains a simple expression for $s_0$ in terms of $\tau$ and $a_{n-1}$.

**Corollary 8.** Let $s_0 \in \mathbb{R}$, $\Delta$ be the quasipolynomial given by (2), and assume that the coefficients of $\Delta$ are given by (19). Then

$$s_0 = -\frac{a_{n-1}}{n} - \frac{n}{\tau}.$$  

The complete proof of Theorem 7 is provided in an extended version of this paper (see Mazanti et al. (2020)) and follows the same lines of the proof of Theorem 3. After a suitable change of variables in order to reduce to the case $s_0 = 0$ and $\tau = 1$, explicit computations of $\Delta^{(k)}(z)$ for $k \in \{0, \ldots, 2n-1\}$ allow computing the coefficients $a_0, \ldots, a_{n-1}, a_0, \ldots, a_{n-1}$ ensuring maximal multiplicity. Dominance of $s_0$ can be established by adapting the arguments from Section 2. Further insight on the sensitivity of the design can be found in Michiels et al. (2017).

4. ILLUSTRATIVE EXAMPLE

Consider the case $n = 3$ and $\tau = 2.5$. We choose $s_0 = -0.5$ as a root of multiplicity 6 for $\Delta$. Then, by Theorem 7, the coefficients $a_0, a_1, a_2, a_0, a_1, a_2$ are given by

$$a_0 = -1.735, \quad a_1 = 2.91, \quad a_2 = -2.1,$$

$$a_0 \approx 1.736219, \quad a_1 \approx 1.443984, \quad a_2 \approx 0.343858.$$  

Figure 2(a) shows the roots of $\Delta$ within the region $\{s \in \mathbb{C} : -5 \leq \Re s \leq 1, -30 \leq \Im s \leq 30\}$, computed numerically using Python’s `xroots` package, which implements numerical methods described in Kravanja and Van Barel (2000). We observe in Figure 2(a) the presence of the multiple root $s_0 = -0.5$ as well as other roots dominated by $s_0$. Figure 2(b) illustrates the stability of (1) with the above choice of coefficients by representing four particular solutions, obtained with the initial conditions $y_{0,i}$ for $i \in \{1, 2, 3, 4\}$ given by

$$y_{0,1}(t) = 1, \quad y_{0,2}(t) = -t,$$

$$y_{0,3}(t) = -\frac{t^2}{4}, \quad y_{0,4}(t) = -\frac{1}{6\omega_0^2} \sin(\omega t),$$

with $\omega = 2\pi$.
