**Learning Point of the Article:**
Anterior release through the standard anterior cervica approach with posterior fixation is a valid option to be considered for the management of neglected odontoid fractures.

**Abstract**

**Introduction:** While odontoid fractures frequently lead to non-union in elderly population, they are relatively rare in the younger age group. We present our management of a rare case of neglected odontoid fracture in an ankylosed spine of a young female.

**Case Report:** A 28-year-old female presented to our emergency department with neck deformity after a history of fall 1 year back. She presented with clinical symptoms and signs of cervical myelopathy. Diagnostic imaging confirmed ankylosis of the cervical spine with a non-union of the odontoid fracture with atlantoaxial instability and kyphosis. She was treated with anterior release of the odontoid through a standard Smith-Robinson approach, anatomical reduction, and posterior occipitocervical stabilization and fusion.

**Conclusion:** Non-union with a malpositioned odontoid fracture in an ankylosed spine can be addressed by an anterior release and reduction with posterior fusion with good functional outcome.

**Keywords:** Non-union, odontoid, ankylosis, cervical spine, myelopathy, anterior release.

**Introduction**
Ankylosing spondylitis (AS) is a progressive, systemic, inflammatory spondyloarthropathy typically affecting the subaxial spine. Cervical spine involvement has been reported in 75% of AS patients [1]. Patients with long-standing AS are 3.5 times more likely to sustain a cervical spine fracture compared to the general population, with a mortality rate of 35%. The majority of these fractures involve the subaxial cervical spine. Upper cervical spine injuries are relatively rare among these patients [2, 3]. Although the numbers of missed fractures are decreasing due to better availability of computed tomographic (CT) scan and magnetic resonance imaging (MRI) [4], injuries of the cervicothoracic junction and the occipitocervical region are still frequently missed due to the absence of neurological symptoms, complex anatomy, suboptimal radiographic images, and low index of suspicion to obtain CT/MRI scans in indicated cases [5, 6, 7].

Neglected odontoid fractures can seldom affect the neurology of the patient. Surgical management of these patients with the symptoms of cervical myelopathy is challenging. We present a novel technique for the reduction and stabilization of neglected odontoid fracture with kyphosis in a case of ankylosed spine.

**Case Report**
A 28-year-old female presented to the emergency department with neck pain, difficulty in balance while walking, and restricted neck range of motion for the past 6 months. She was a diagnosed case of AS not under regular follow-up. She had sustained injury to her neck, 1 year back due to a fall which was managed conservatively. On examination, she had near-complete restriction of neck movements and weakness of her...
The patient was then positioned prone using the Mayfield’s clamp. The adequate reduction was ensured under fluoroscopic guidance. The standard posterior approach was performed to expose the atlantoaxial and occipitocervical region. C1-C2 joint was curetted, wedge-shaped bone graft was placed and fusion performed along with posterior fusion from occiput to C5 using occipital plate and lateral mass screws at C1, C3, C4, and C5. C1-C2 joint was reduced using DCER (distraction, compression, extension, and reduction) technique; hence, decompression was deferred as joint was reduced anatomically [8]. Sublaminar wires were used at the C2 lamina. The construct was stabilized with pre-bent rods. Posterior fusion was performed using cancellous graft chips obtained from the right posterior iliac crest (Fig. 2c).

Surgical technique

With the patient in the supine position, the Smith-Robinson approach to the cervical spine was performed through a horizontal skin incision at the C5-C6 level. Following this, the anteriorly subluxated arch of C1 was palpated, and the non-union site was marked with a K-wire under fluoroscopy guidance. An osteotome was then gently advanced into the non-union site under fluoroscopy guidance, and osteoclasis was performed (Fig. 2a and b). Care was taken to avoid inadvertent injury to the cord. Once osteoclasis was performed, rest of the adhesions were released from the anterior aspect of the spine. The cervical spine was repositioned in gentle lordosis under fluoroscopic guidance, and satisfactory restoration of alignment of C1-C2 was confirmed.

The patient was then positioned prone using the Mayfield’s clamp. The adequate reduction was ensured under fluoroscopic guidance. The standard posterior approach was performed to expose the atlantoaxial and occipitocervical region. C1-C2 joint was curetted, wedge-shaped bone graft was placed and fusion performed along with posterior fusion from occiput to C5 using occipital plate and lateral mass screws at C1, C3, C4, and C5. C1-C2 joint was reduced using DCER (distraction, compression, extension, and reduction) technique; hence, decompression was deferred as joint was reduced anatomically [8]. Sublaminar wires were used at the C2 lamina. The construct was stabilized with pre-bent rods. Posterior fusion was performed using cancellous graft chips obtained from the right posterior iliac crest (Fig. 2c).

The post-operative period was uneventful, and the patient was advised to use the soft cervical collar for 3 months. By the end of 3 months, she recovered significantly from her myelopathic symptoms. CT scan performed at the end of 1 year demonstrated a well-reduced atlantoaxial joint adequate space available for cord and a maintained cervical sagittal alignment with sound fusion at C1-C2 joint (Fig. 3a and b).

Discussion

Ankylosed cervical spine results in a long lever arm, with a 5-fold higher risk of spine fractures in comparison to the healthy population [9]. Delay in diagnosis is due to the often trivial nature of injury resulting in a fracture and junctional anatomical locations such as the occiptocervical and cervicothoracic junctions [7]. Odontoid fractures are relatively rare in ankylosed spine, and the consensus regarding the treatment options is yet to be achieved [2]. Giannoudis et al. [10] reported a significant association between non-union and NSAIDs,
In addition to the soft-tissue contractures, bony changes develop over time and play a role in the irreducibility of the fracture. The articular surfaces of C1–C2 may become gradually more vertical and arthritic. The union may prevent the reduction of C1 over C2. Our patient had AS; she not only presented with the arthritis of the C1-C2 joint, but the rest of her subaxial cervical spine was ankylosed. Often, these injuries cannot be treated with conventional surgical techniques and require improvised approaches. Multiple treatment options have been reported in literature. Reports of anterior odontoidectomy followed by posterior fusion have shown satisfactory outcomes [13, 14], especially with the advent of microsurgical techniques. However, the transoral odontoid resection has a steeper learning curve and carries a small but significant risk of dural tear leading to meningitis. In transoral odontoidectomy, it is difficult to correct the kyphosis and reduce the C1-C2 joint, which may result in a swan neck deformity [15]. Wang et al. reported excellent results with the transoral release of the odontoid followed by posterior fusion, even in severe atlantoaxial dislocations [15]. The anterior release can be done transorally or through the retropharyngeal approach. The crucial advantage of this technique is the anatomical reduction and prevention of progressive neck deformity. Furthermore, the complications associated with dural tears are avoided. Microendoscopic anterior release and video-assisted transcervical release have also been reported in recent literature [15, 16].

Goel et al. described posterior atlantoaxial joint release and distraction for irreducible atlantoaxial dislocations. However, it works well only in the less severe irreducible dislocations [17]. This procedure of posterior distraction falls short in addressing the anterior tether in chronically dislocated joints. Rishi et al. described the single-stage anterior release of atlantoaxial joint along with contracted muscles and followed by posterior stabilization for neglected odontoid fracture with atlantoaxial dislocation [18].

In the present case, we performed the release of odontoid through the standard anterior retropharyngeal approach followed by posterior stabilization and fusion with an occipital plate and lateral mass screws. At the end of 6 months follow-up, radiographs demonstrated sound fusion with satisfactory cervical alignment. The patient had complete neurological recovery.

**Conclusion**

Anterior release and posterior fusion can provide sufficient decompression, adequate deformity correction, and sound fusion in cases with neglected odontoid fractures in the ankylosed spine while avoiding the pitfalls associated with the odontoidectomy. Our technique of anterior release of the odontoid (using standard anterior approach) with posterior fusion has shown good clinical outcome and anatomical restoration of sagittal alignment.

**Clinical Message**

Irreducible atlantoaxial dislocation is addressed by anterior and posterior approach. The described technique avoids the complications of transoral surgeries. One should be vigilant in releasing the adhesions anteriorly to reduce the joint in anatomical position.
