This paper is concerned with the synthesis, characterization, and electrochemical properties of all solid state dye-sensitized solar cells (SSDSSCs) with a dense TiO₂ layer. The dense TiO₂ layer, which was prepared from titanium hydroxide and titanium tetra isopropoxide precursor, has been characterized by X-ray diffraction, scanning electron microscopy. The experimental results showed that the TiO₂ layer formed using titanium hydroxide precursor with a thickness of about 100 nm was composed of crack free anatase-phase. The dense TiO₂ layer is found to improve the short circuit current density (Jsc), leading to enhancement in the conversion efficiency (η) of the SSDSSCs from 2.92 to 3.60%.

Key-words : Solid state dye-sensitized solar cells, Blocking layer, Interface, Titanium dioxide, PEDOT, CuI

1. Introduction

Recently dye-sensitized solar cells (DSSCs) have been intensively studied because of their low cost and high efficiency comparable to amorphous silicon solar cells.¹⁻³ However, normal DSSCs using liquid electrolytes have several technological problems such as dye desorption, solvent evaporation, leakage and so on. Much effort for solving them has been made to replace the liquid electrolyte with quasi-solid or solid materials.⁴⁻⁶ Organic hole conductors are suitable as hole conductors in SSDSSCs because these materials have high optical transmittance, high electrical conductivity and suitable valence band energy level which allows hole injection from excited ruthenium dye molecules. However, SSDSSCs exhibit largely low conversion efficiency in comparison with normal DSSCs using liquid electrolyte. The reasons are as follows; solid hole conductors penetrates porous TiO₂ layer resulting in direct contact with the transparent conductive glass electrode, and it may cause short-circuit. Therefore, it is necessary to form a dense blocking layer between porous TiO₂ layer and transparent conductive glass electrode to prevent them from direct contact. It is well known that compactness of the blocking layer dominates performance of SSDSSCs.²⁶ However, a precursor of the titanium alkoxide which has been usually used for the formation of blocking layer is useless to prepare dense blocking layers, since cleavage due to decomposition and evaporation of bulky alkoxide groups during heat-treatment may be left in the layer.²⁶

In this paper, we propose better method for preparation of the dense TiO₂ blocking layer on FTO through an alkoxide group free precursor. By the use of the present method, it is found that CuI based SSDSSCs with the dense TiO₂ blocking layer shows enhancement in the conversion efficiency (η) mainly due to the improvement of the short-circuit current (Jsc).

2. Experimental

2.1 Preparation of TiO₂ blocking layer

Titanium tetra-isopropoxide (0.47 g), ethanol (3.95 g), and hydrochloric acid (30%, 0.13 g) was mixed together and stirred for 1 h (solution A).

Titanium (IV) chloride solution (16.5%, 2.32 g) and water (13.5 g) were mixed and stirred for 1 h. Subsequently, ammonia solution was added to the resultant solution so as to adjust the pH at 8, leading to the formation of precipitates. The precipitates were separated through filtration, washed, and collected. Tetramethyl ammonium hydroxide solution (15%, 3.0 g) was added to the precipitates. The mixture was stirred for 24 h at 60°C, in order to form a transparent clear solution (solution B).

Blocking layers were prepared by spin-coating of the solutions A and B on a FTO glass substrate (Asahi glass). Subsequently, in order to prepare transparent titanium oxide films, each substrate was dried at 100°C for 10 min in air, and heated at 500°C for 30 min in air.

2.2 Fabrication of SSDSSC

Porous TiO₂ films were prepared by coating the TiO₂ paste onto the blocking layer/FTO glass substrate using the squeeze printing technique, subsequently, the electrodes were heated at 500°C for 30 min in air. The thickness of porous TiO₂ film was about 7 μm. The electrode was immersed in 0.5 mM ethanol solution of N3 dye for 24 h at room temperature. The C.I. acetonitrile solution (0.15 M) was lightly coated over the dyed electrode. After coating, the electrode was heated up to 80°C to evaporate the solvent. This process was repeated several times. The amount of CuI solution was about 0.06 ml/cm². The counter electrode was prepared by coating the solution of polyethylene glycol (PEG) containing NCS group onto the ITO modified by poly(3,4-ethylene-dioxy-thiophene-poly(styrene-sulfonate) (PEDOT-PSS). The PEDOT modified ITO was prepared by spin-coating of PEDOT-PSS aqueous dispersion (Clevios PH) on ITO and dried at 130°C for 30 min in air. The PEG contain-
ing NCS groups was prepared by dissolving PEG20000 and guanidium thiocyanate (1:1) in acetonitrile and heated up to 130°C to evaporate the solvent. The CuI/dye/porous-TiO2/ blocking layer/FTO electrode was fixed together with the counter electrode. The resulting cells had an active area of 0.24 cm².

2.3 Characterization

The local structure of the samples were examined by the use of fourier transformation infra-red spectrometer (FT-IR) (Perkin Elmer, SPECTRUM GX 2000R). The photo-electrochemical properties of the SSDSSCs were measured by recording the current-voltage (I-V) characteristics under illumination of AM 1.5 (1 Sun; 100 mW/cm²) using a solar simulator (Yamashita Denso, YSS-80). The electrochemical impedance spectroscopy (EIS) of the SSDSSCs was conducted using a potentiostat (Solartron analytical, model 1287) equipped with an impedance analyzer (Solartron analytical, model 1260) under illumination of AM 1.5 using the solar simulator. The EIS measured in the frequency range of 0.1–10⁶ Hz and the AC amplitude was 50 mV and set at open circuit voltage. The phase of TiO2 blocking layer was identified by X-ray diffraction (XRD) with monochromatic Cu Kα radiation at 30 kV, 20 mA (Philips, PW1790). The thickness and morphology of the blocking layers were examined by the use of a field-emission scanning electron microscope (Hitachi, S-4100). Thermo-gravimetric analysis (TG) and differential thermal analysis (DTA) were conducted using a TG/DTA thermal analyzer (Seiko Instruments TG/DTA300, 10°C/min) to characterize the solution A and B after dried at 70°C.

3. Result and discussion

3.1 FT-IR characterization

Figure 1 shows the FT-IR spectrum of the samples from solution B and titanium hydroxide after they were dried at 40°C. This broad peak is presumed to be caused by the bending vibration of H₂O as well as Ti-OH. Comparing the peak intensity with each other, the broad peak for the sample from solution B after dried at 40°C is weakened, indicating that the hydroxyl groups reduced for the sample from solution B.

3.2 Analysis of the dense TiO2 layer

Figure 2 shows the typical XRD patterns of the FTO and dense TiO2 layer-deposited FTO glasses. In Fig. 2(a), the diffraction peaks can be identified as a tetragonal rutile phase SnO₂. In Fig. 2(b), a newly appeared peaks corresponding to the (101) of anatase-phase TiO2 are observed.

3.3 Thermal analysis

Figure 3 shows the TG/DTA curves of the samples from solutions A and B dried at 70°C. In the TG curves, the total weight loss of those from solutions A and B in the temperature region up to 500°C are about 50 and 40%, respectively. Additionally, since the sample from solution B was pyrolyzed at lower temperature under 250°C, it may give rise to less thermal

Fig. 1. FT-IR spectrum of the solution B and titanium hydroxide after dried at 40°C in vacuum.

Fig. 2. XRD patterns of (a) the bare FTO and (b) the FTO covered with dense TiO2 blocking layer, FTO (square) and TiO2 (circle).

Fig. 3. Surface (A–C) and cross-section (a–c) SEM images for the bare FTO, blocking layer-deposited FTO substrates from the solutions A and B.
Therefore, it is speculated that the crack-free dense TiO₂ layer was formed from solution B probably due to the small total weight loss during heating and less thermal contraction.

### 3.3 Photovoltaic performance

The I–V curves of the DSSCs with and without the blocking layer are shown in Fig. 5 and the photovoltaic characteristics of these DSSCs were summarized in Table 1. Comparing with the DSSCs without the blocking layer, the performance of the SSDSSCs with the dense blocking layer, in terms of solar energy conversion efficiency (η) and short-circuit current density (Jsc), was improved by 23.3% and 30.4%, respectively. One of the main factors improving the Jsc of the SSDSSCs may be the charge recombination at the FTO and CuI interfaces. It is reported in a previous study that the Jsc is associated with the charge recombination at photocathode electrodes. Figure 6 is the comparison of the dark photocurrent characteristics of DSSCs with and without blocking layer. The onset of the dark current shifted to higher forward bias for the DSSCs with blocking layer. The increase of the onset potential and the reduction of the dark current demonstrated that the blocking layer successfully reduced the recombination. With the application of the dense blocking layer, the number of the recombination sites (bare FTO surface) are reduced, leading to reduction of the charge recombination in the SSDSSCs.

### 3.4 Electrochemical impedance spectroscopy

Figure 7 shows the electrochemical impedance spectra measured in the frequency range of 0.1–10⁶ Hz for the cell with no treatment and that treated with solution B at open circuit conditions. According to our previous study, the counter electrode containing NCS groups as well as the NCS groups of the dye molecules were thought to interact with CuI. The specific interaction of CuI with the NCS groups of both electrodes could promote the injection of the hole into the electrodes. Based on our previous studies, the equivalent circuit of these cells composed of three RC parallel circuit is shown in Fig. 8. \( R_1C_1 \), \( R_2C_2 \), and \( R_3C_3 \) corresponding to charge transfer resistances and electrochemical capacitances are thought to be due to the dye on TiO₂/CuI, CuI/guanidium thiocyanate, guanidium thiocyanate/PEDOT:PSS interface, respectively. \( R_0 \) indicates the series internal resistance of SSDSSCs such as the resistance of transparent conducting glasses. These values of \( R, C \), and \( \alpha \) [phase of Constant Phase Elements: \( Z_{CPE} = 1/(1+(j\omega)^\alpha) \)] were calculated by fitting the components of the equivalent circuit with Z-view software and are exhibited in Table 2. \( R_1 \) corresponding to the resistance of TiO₂-dye/CuI for the cell with no treatment showed almost the same value as that of the cell treated with solution B.

---

**Table 1. Photocurrent-voltage characteristics values of SSDSSCs**

|               | Voc (mV) | Jsc (mA/cm²) | F.F. | η (%) |
|---------------|----------|--------------|------|-------|
| No treatment  | 547      | 10.2         | 0.525| 2.92  |
| Solution A    | 532      | 11.7         | 0.512| 3.17  |
| Solution B    | 549      | 13.3         | 0.494| 3.60  |

---

**Fig. 4.** TG/DTA curves of the solution A and B after dried at 70°C.

**Fig. 5.** Photocurrent-voltage characteristics of SSDSSCs.

**Fig. 6.** Dark photocurrent-voltage characteristics of SSDSSCs.

**Fig. 7.** Nyquist diagrams of impedance spectra obtained under illumination for the cells with no treatment (triangle) and the cell with blocking layer treated with solution B (square).
As for $R_2$, the cell treated with solution B showed a smaller value than the cell with no treatment. It is speculated that the hole transport was promoted at the CuI/guanidinium thiocyanate interface. We presume that the improvement of hole transport was caused by the reduction of the recombination at the FTO/CuI interface.

4. Conclusion

A TiO$_2$ layer from titanium hydroxide precursor solution has been developed as the dense blocking layer at the FTO/porous-TiO$_2$ interface. The crack-free TiO$_2$ blocking layer was formed from solution B which had small total weight loss during heating and less thermal contraction during pyrolyzing at lower temperature. The electrode treated with solution B was presumed to enhance $J_{sc}$, leading to the improvement of the conversion efficiency from 2.92 to 3.60%. One of the main factors improving the $J_{sc}$ of the SSDSCs may be reduction of the charge recombination at the FTO and CuI interfaces. The electrochemical impedance measurements revealed that the dense blocking layer reduced charge recombination of SSDSCs at the interface between FTO and CuI.
