Abstract

**Introduction:** *Staphylococcus aureus* constitutes the most pathogenic species within the staphylococcal genus. Humans remain the major reservoirs of this pathogen which colonizes mostly anterior nares of healthy individuals.

**Aim:** To investigate the effect of fennel essential oil (FEO) and *trans*-anethole (tA) on antibacterial activity of mupirocin (MUP) against *S. aureus* strains isolated from asymptomatic carriers.

**Material and methods:** The content of the FEO was analysed with use of the GC-MS method. The research done on 43 *S. aureus* isolates with different resistance patterns, obtained from nasal vestibule. Antibacterial activity of MUP in combination with FEO or tA was examined using the agar dilution method and E-test method. The data analysis was done with the Pearson’s χ² test.

**Results:** The chemical composition of FEO was consistent with the European Pharmacopoeia (EP) for the main constituent – *t* A (77.9%) according to the EP recommendations. Macrolide-lincosamide-streptogramin B resistance phenotype was prevalent among 39.5% of *S. aureus* isolates. FEO concentrations of 2.0% and 2.5% revealed antibacterial activity against 76.7% of isolates, whereas *t* A inhibited *S. aureus* growth at concentrations > 4.0%. The MIC values for MUP combined with FEO as well as for MUP combined with *t* A were < 0.064 µg/ml for 79.1% and 86.0% of *S. aureus* isolates, respectively.

**Conclusions:** Our experiment revealed FEO and *t* A influence on MUP effectiveness. The combination of MUP with FEO as well as MUP with *t* A are worth considering to implement in *S. aureus* eradication procedures. These findings will be useful in designing efficient antistaphylococcal agents which can limit the emergence of antibiotic resistance.

**Key words:** *Staphylococcus aureus*, mupirocin, fennel essential oil, *trans*-anethole.

Introduction

An extensive transmission of *Staphylococcus aureus* between humans is known to be significantly attributed to asymptomatic carriers. The percentage of persistent carriers of *S. aureus* in anterior nares is reckoned to be about 20%, whereas the transient nasal carriers and non-carriers account for 60% and 20%, respectively. The persistent carrier-state is being more frequently observed among young children than adults; however the incidence of *S. aureus* carriage among listed groups undergoes numerous changes in individuals aged between 10 and 20 [1]. Higher rates of nasal colonization are observed in hospital staff (around 44%), which doubtlessly poses a great risk of *S. aureus* transmission to hospitalized patients [2, 3].

The carriage of *S. aureus* among medical staff represents an outstanding problem because these can transfer multidrug staphylococcal strains to medical students, other medical staff, and, most importantly, to hospitalized patients. It is estimated that the nasal carriage of *S. aureus* among medical staff ranges between 16.8% and 56.1% [1]. Nasal colonization with *S. aureus* is a risk factor for endogenous staphylococcal infection, especially in patients undergoing surgical procedures with simultaneously reduced immunity. Thus, the eradication is needed in carriers to reduce the risk of infection.
Available guidelines recommend a topical application of mupirocin (MUP) on mucosal membranes of anterior nares to eradicate the S. aureus colonization (methicillin-sensitive S. aureus – MSSA and methicillin-resistant S. aureus – MRSA). Due to a high incidence of re-colonization in individuals treated with MUP, it is recommended to use the ointment for at least several weeks [4]. The worldwide increase in resistance to MUP among S. aureus explains the need to evaluate the susceptibility to MUP of each S. aureus isolate as well as the necessity to search for new treatment options such as application of essential oils which express good antimicrobial properties [5].

Foeniculum vulgare Mill. (fennel), biennial plant belonging to the Apiceae family has been easily adapted to many geographic regions [6]. Due to its unique taste, aroma and antimicrobial action, fennel is used in food and cosmetic industry [7]. Fennel is also used to treat gastrointestinal and respiratory tracts disorders. It is known to cause intestinal smooth muscles relaxation and to dissolve bronchial secretion, thus to facilitate easier expectoration. Moreover, the fennel seed extract promotes milk supply in breasts of feeding mothers, assuages period pains, increases sex drive and facilitates birth. Available studies reveal that fennel essential oil (FEO) displays antimicrobial, antioxidant, anti-inflammatory, anti-cancer, anti-spasmodic, anti-coagulant, anti-diabetic, cholagogue, diuretic, anti-hypertensive, hepatoprotective and acaricidal properties [8–10].

FEO is composed mostly of trans-anethole (tA) and fenchone followed by camphene, estragole, limonene, α-pinene, β-pinene, β-myrcene, camfor, 3-carene, α- phellandrene and cis-anethole [9].

tA (p-metoxypenylbenzene) is an organic compound, a by-product of terpene synthesis. It constitutes the major ingredient of many essential oils – anise (Pimpinella anisum L.), star anise (Illicium verum Hook. f.) and fennel (F. vulgare Mill.). tA is widely used in food industry, but also in cosmetic and health-care industries [11, 12]. Existing evidence proves its antimicrobial, insecticidal, larvicidal and antioxidative properties [7, 13].

**Aim**

The aim of the study was to evaluate the influence of FEO and tA on antibacterial activity of MUP against S. aureus strains isolated from asymptomatic carriers.

**Material and methods**

**Strains and their susceptibility to antimicrobial agents**

Staphylococcus aureus strains were isolated from medical faculties’ students during the 2-years study, in the years 2014–2015 at Department of Microbiology, Immunology and Laboratory Medicine of Pomeranian Medical University in Szczecin, Poland. During the study period, 43 bacterial strains from anterior nares swabs have been collected and routinely all were identified with S. aureus screening assay. The specimens were cultivated on Columbia agar with 5% sheep blood (bioMérieux, Poland), identified by colony morphology, tube coagulase test (Biomed, Poland), Staph-Kit test (bioMérieux, Poland) and biochemical test GP Viték 2 Compact (bioMérieux, Poland). S. aureus ATCC® 29213™ strain was used to determine the optimal concentration of FEO and tA in combination with increasing (E-test method) concentrations of MUP (bioMérieux, Poland).

The susceptibility to ciprofloxacin, co-trimoxazole and MUP of S. aureus isolates was assessed via disc diffusion method and interpreted according to the European Committee on Antimicrobial Susceptibility Testing (EUCAST) recommendations. MRSA phenotype was determined using cefoxitin. The presence of macrolide-lincosamide-streptogramin B (MLS) resistance phenotype was determined using erythromycin and clindamycin in accordance with Clinical and Laboratory Standards Institute (CLSI) recommendations [14–17]. Antibiotic discs were provided by Diag-Med, Poland.

**FEO and tA origin**

FEO purchased from Pollena-Aroma (Poland) was used in this study. The essential oil was analysed by gas chromatography-mass spectrometry (GC-MS) at the Faculty of Chemical Technology and Engineering, West Pomeranian University of Technology in Szczecin. The main constituent of tested essential oil was tA (77.9%) followed by fenchone (12.8%), α-pinene (3.8%), estragole (2.3%), limonene (2.1%) [14].

tA with a purity of not less than 99.0% was obtained from Sigma-Aldrich, Germany.

**Susceptibility of S. aureus to FEO and tA**

The agar dilution method mirrored the one approved by CLSI [18] with the following modification: a final concentration of 1.0% (v/v) Tween® 80 (Sigma-Aldrich, Germany) was incorporated into Mueller-Hinton Agar (MHA) (Sigma-Aldrich, Germany) after autoclaving in order to enhance FEO and tA solubility. FEO and tA at various concentrations (0.1%, 0.25%, 0.5%, 0.75%, 1.0%, 1.5%, 2.0%, 2.5%, 3.0%, 3.5%, 4.0%) (v/v) were independently transferred into MHA with 1.0% (v/v) Tween® 80. Plates were dried at 37°C for 30 min prior to inoculation of each them with suspension containing approximately 10¹⁵ CFU/ml of particular S. aureus isolates, using a multichannel pipette. MHA with 1.0% (v/v) Tween® 80 without FEO or tA was used as a positive growth control for S. aureus. Minimal inhibitory concentration (MIC) of each tested ingredient was determined after 18 h incubation and recognized as the lowest concentration of oil which completely inhibited the visible growth of S. aureus on MHA plate. According
to CLSI recommendations, a single colony or a faint haze caused by the inoculum was disregarded [18].

**Determination of the optimal concentration of FEO and tA in combination with MUP**

Determination of the optimal FEO and tA concentration enhancing antibacterial activity of MUP was assessed using ATCC® 29213™ strain of *S. aureus*. The optimization was performed using the agar dilution method and E-test method. For screening of the optimal concentrations of FEO and tA enhancing antibacterial activity of MUP, various concentrations (0.1%, 0.25%, 0.5%, 0.75%, 1.0%, 1.5%, 2.0%, 2.5%, 3.0%, 3.5%, 4.0%) (v/v) of these chemicals were distributed into MHA with 1.0% (v/v) Tween® 80. Plates were dried for 30 min at 37°C prior to inoculation with sterile cotton swab containing approximately 10⁶ CFU/ml of microorganism. Then, the activity of the antibiotic was studied by applying a plastic test strip (E-test) which consisted a predefined, continuous and exponential gradient of MUP on the surface of MHA plates (with and without chemicals – control). The plates were incubated for 18 h at 37°C in aerobic conditions. After incubation, the MIC of MUP were calculated. Each test was performed with two replicates.

**Antibacterial activity of MUP in combination with FEO or tA**

Antibacterial activity of MUP in combination with FEO or tA was examined using the agar dilution method and E-test method in comparison with optimal concentrations revealed by optimization assay. For the screening of antibacterial activity of MUP combined with chemicals, the optimal concentration (v/v) of the chemicals was distributed in MHA with 1.0% (v/v) Tween® 80. Plates were dried for 30 min at 37°C prior to inoculation with 10⁶ CFU/ml of bacterial suspension. The activity of the antibiotic was studied by applying a plastic test strip (E-test) with a continuous and exponential gradient of MUP on the surface of MHA plates (with and without chemicals – control). The plates were incubated for 18 h at 37°C in aerobic conditions. The MIC values were calculated.

**Ethical statement**

The study was approved (KB-0012/04/01/14) by the Ethics Committee of the Pomeranian Medical University of Szczecin, Poland.

**Statistical analysis**

Comparison of the study data was done using the Pearson’s χ² test. Statistical analyses were performed using the Statistica programme version 12.5. A *p*-value < 0.05 was considered statistically significant.

**Results**

**Screening of bacterial susceptibility to antibiotics**

All *S. aureus* strains isolated from the asymptomatic carriers, when tested by disc diffusion method, were susceptible to MUP and to cefoxitin (confirmed MSSA phenotype), whereas one of them showed resistance to ciprofloxacin and another one to co-trimoxazole. The resistance to erythromycin and clindamycin was observed in 39.5% of the isolates. The presence of inducible MLSB and constitutive MLSB resistance phenotypes was indicated in 34.9% and 4.7% of the strains, respectively. None of the isolates had MSB resistance phenotype. *S. aureus* ATCC® 29213™ was susceptible to all antibiotics.

**Determination of MICs of FEO and tA**

Our investigation showed that FEO in concentrations of 2.0% and 2.5%, represented an inhibiting activity against 76.7% (*p* < 0.0001) of *S. aureus* isolates. tA had much weaker inhibitory activity against staphylococci. An equal number of tested isolates (74.4%) were susceptible to tA at a concentration higher than 4.0% (*p* < 0.0001) (Table 1). The minimal concentrations of FEO and tA inhibiting growth of *S. aureus* ATCC® 29213™ cells were 2.0% and > 4.0%, respectively. It was also observed that the addition of 1% Tween® 80 has no impact on growth inhibition of reference strain and isolates.

**Optimization of FEO and tA concentrations against *S. aureus* ATCC® 29213™**

The optimal concentrations of FEO or tA, enhancing the activity of MUP against reference *S. aureus* strain were 0.75% for FEO and 1.5% for tA. It was observed that the addition of FEO and tA to MHA with 1% Tween® 80 decreased the MIC of MUP from 0.25 μg/ml to ≤ 0.064 μg/ml (Figure 1). The minimal concentration of MUP combined with 0.75% FEO and 1.5% tA (which has been recognized to inhibit the growth of reference strain), was lower than 0.064 μg/ml (Figure 2). It was also noted that the addition of 1% Tween® 80 had no impact on the MIC value of MUP alone.

**Influence of FEO or tA on antibacterial activity of MUP**

A significant increase in antistaphylococcal activity of MUP combined with FEO or tA was confirmed by the agar dilution method and E-test method. The influence of FEO or tA used in combination with MUP was comparable. MICs of MUP combined with FEO and MUP combined with tA were < 0.064 μg/ml for 79.1% (*p* < 0.0001) and 86.0% (*p* < 0.0001) of *S. aureus* isolates, respectively. However, MICs of MUP without FEO or tA were 0.19–0.125 μg/ml for 69.8% of *S. aureus* strains. The addition of FEO or tA to MHA reduced MIC values from 0.17 ±0.07 μg/ml to 0.064 μg/ml (*p* < 0.0001), but
The effect of fennel essential oil and trans-anethole on antibacterial activity of mupirocin against *Staphylococcus aureus* isolated from asymptomatic carriers

The largest number of isolates (34 and 37 strains of *S. aureus*, respectively for FEO and tA) were inhibited by a concentration lower than 0.064 μg/ml (*p < 0.0001). No correlation was found between resistance phenotypes and susceptibility towards MUP with FEO or tA combinations (Table 1).

### Discussion

The anethole-dominated FEO represents one of the two reference FEO chemotypes accepted by Pharmacopoeia for medical application [19]. The content of tA in FEO ranges from 38.8% (Albania, Yugoslavia) to 84.1% (Turkey, Albania) and is dependent on its geographical origin. The content of tA in our tested FEO was close to French and Argentinean fennel oil; those contain 75.5% and 79.9% of tA, respectively [20]. The European Pharmacopoeia (EP) requires minimum 60% of tA in bitter FEO composition. The remaining needed components are as follows: 15% of fenchone, 1–10% of α-pinene; not more than 6% of estragole and 1–5% of limonene. The chemical composition of the tested FEO was consistent with EP requirements regarding tA, α-pinene, estragole and...
Figure 2. Minimum inhibitory concentration of mupirocin against S. aureus ATCC® 29213™: A – Mueller-Hinton Agar (MHA) supplemented with 1% (v/v) Tween® 80 without fennel essential oil (FEO) or trans-anethole (tA), B – MHA supplemented with 1% (v/v) Tween® 80 and 0.75% FEO, C – MHA supplemented with 1% (v/v) Tween® 80 and 1.5% tA

limonene. The content of fenchone was slightly lower when compared with reference data.

According to the available data, the increase in resistance among S. aureus to macrolide, lincosamide and streptogramin B antibiotics is being observed [21]. The presence of MLSB resistance mechanism among staphylococci excludes treatment with the above-mentioned antibiotics, while it is known that erythromycin and clindamycin are commonly used in empirical treatment of Gram-positive bacteria infections. Clindamycin is an alternative therapeutic option for the treatment of staphylococcal skin and soft tissue infections, but also an alternative for patients with penicillin allergies [22]. The degree of resistance to macrolides among MRSA is still increasing, as well in MSSA, and this constitutes a significant challenge for clinicians dealing with skin infections [23, 24]. According to the study of Yilmaz et al., the inducible MLSB resistance phenotype was detected in 14.8% of MSSA isolates [25]. Similar results were obtained by Prabhu et al., who reported that constitutive and inducible MLSB resistance phenotype among MSSA occurred in 18% of isolates from different clinical samples [22]. Our results indicate that medical staff is a significant factor in the spread of pathogens resistant to macrolide, lincosamide and streptogramin B antibiotics. Therefore, there is a need for continuous monitoring of this type of bacterial resistance and implementation of new methods to prevent the spread of resistance.

In our previous study we obtained promising results and indicated that FEO was the most effective in combination with MUP [14]. Using the disc diffusion method, the increasing zone of growth inhibition of S. aureus was found. We further decided to design an exact research using the agar dilution method and E-test method against higher number of isolates from nasal vestibule with different patterns of resistance. We studied not only the combination of FEO with MUP, but also the combination of FEO main component – tA with MUP which, according to available data, improves cutaneous wound healing. This provides data on its oral LD50 values between 1.8–5.0 g for mice, rats and guinea pigs [26, 27]. It can be concluded that antimicrobial activity of FEO compared with tA is determined by more than one particular component, and depends on the synergistic activities of different oil constituents. This is even despite tA high content. The MIC values of FEO were much lower than MICs of tA, ranging from 1.5 to 2.5% and from 3.0 to > 4.0%, respectively. Summarizing, better results were obtained when combined FEO with MUP. The similar results were presented by Kazemi et al. in the study on antistaphylococcal activity of FEO containing mainly tA, thymol, α-pinene, 1,8 cineole and fenchone [28]. They found that analysed FEO was more effective against human pathogenic S. aureus with MIC – 0.5 μg/ml than the main constituent – tA itself (MIC – 4.0 μg/ml). Only pure thymol presented comparable activity to phenolic compounds of this oil. Lachowicz et al. showed the lesser antimicrobial activity of artificially prepared main constituent mixture (linalool-estragole) compared with anise oil [29]. These results indicated that other less predominant components in anise oil most likely contribute to its antimicrobial activity.

Many scientific centres are investigating effective combinations of chemical agents as well as compounds of natural origin on decrease the resistance of microorganisms. Itaqui et al. investigated the interactions between azithromycin and terbinafine in combination with MUP in order to reduce the therapeutic doses of systemic and local treatment against Pythium insidiosum responsible for ocular, cutaneous/subcutaneous, vascular and disseminated pythiosis [30]. Sato et al. found a synergistic effect of MUP and isoformavanone (Bidwillon B) obtained from Erythrina variegata against MRSA [31]. The results showed that Bidwillon B appears to be not only a strong antistaphylococcal agent itself, but also combined with MUP, and thus can be helpful in the elimination of nasal
and skin MRSA carriage. According to the findings of Kifer et al., some combinations of MUP and monoterpenes such as menthol, thymol, 1,8-cineole could be applied in the therapy of infections caused by S. aureus, including chronic rhinosinusitis [32]. In this case, the treatment is based on bacterial biofilm growth prevention. Because of the common use of MUP for staphylococci eradication in patients and medical staff, there is a risk of a significant resistance rate increase in the future. The new active compounds actingadditively or synergistically with MUP can be effective in prevention of the resistance to this antibiotic.

Conclusions

Our investigation showed that FEO or tA could be added to mupirocin-based agents to eradicate the nasal carriage of S. aureus and/or to limit the emergence of mupirocin resistance as well. The FEO or tA combined with MUP tested in the study was effective against MLSB resistant S. aureus isolates and such combination/s may be helpful in nasal eradication of staphylococci with some patterns of resistance. This is not excluded, that in the coming future the FEO or tA will be components of agents to mucous membranes antisepsis, but more research in this field are required.
