Abstract
Schwinger’s quantization scheme is extended in order to solve the problem of the formulation of quantum mechanics on a space with a group structure. The importance of Killing vectors in a quantization scheme is showed. Usage of these vectors provides algebraic properties of operators to be consistent with the geometrical structure of a manifold. The procedure of the definition of the quantum Lagrangian of a free particle and the norm of velocity (momentum) operators is given. These constructions are invariant under a general coordinate transformation. The unified procedure for constructing the quantum theory on a space with a group structure is developed. Using it quantum mechanics on a Riemannian manifold with a simply transitive group acting on it is investigated.

1 Introduction
There are many works [1]-[13] where authors have represented the formulations of quantum mechanics on spaces with a group structure. These investigations have been carried out not only for the sake of academician interest, but also for particular applications. The development of quantum mechanics on curved spaces has been essentially stimulated by fruitful investigations of several non-linear models such as the quantized Skyrme model of simplest baryons [6] - [9], the theory of three dimensional quantum chiral solitons [10], [11] and supersymmetrical [12] fermi-solitons. The main interest in these works has been caused by the problem of determination of a so-called “quantum potential” and the gauge structure of quantum mechanics on a curved space (or a surface embedded into the Euclidean space). An operator ordering problem in the starting Lagrangian has not been exhaustively analyzed in these works. Moreover, some assumptions (which seem to be truthful) are used in explicit or hidden form without any rigorous definition.

In this connection we try to examine the complex of problems associated with quantum mechanics on a curved space equipped with a Riemannian metric and to give (as it possible) the rigorous motivation of it. Our version of the formulation of quantum mechanics on a curved space is based on Schwinger’s action principle [14]. Developing a quantization procedure, we
show that permissible variations (appearing in the action principle) on such a manifold coincide with Killing vectors which represent the group of isometries for the Riemannian metric. Hence, the quantum-mechanical properties of the theory (an operator algebra and a gauge structure) are determined by this group.

The use of this procedure enable one to construct the quantum Lagrangian by a rigorous way and to treat a “quantum potential” as a correction in the quantum Lagrangian which makes it a quantum scalar under a general coordinate transformation. We also introduce the definition of the scalar norm of momentum and velocity operators which plays an important role in constructing the quantum Lagrangian.

Our results, obtained by means of this procedure, are represented in three papers. In the present work (first of them) we carry out the main principles and extension of Schwinger’s quantization procedure for the case of a Riemannian space which is applied in order to construct quantum mechanics on a manifold with the simply transitive group of isometries acting on it. Here Killing vectors form the representation of the Lie algebra and its number is equal to the dimension of a manifold. In this case Schwinger’s quantization procedure is realized without any difficulties and obtained results are in accordance with [1].

In the second paper we will consider the more complicated case of quantum mechanics on a homogeneous Riemannian manifold $V_n$. The number of Killing vectors is bigger than the dimension of the manifold and they are not independent in a point $q_0 \in V_n$. Some of them form the representation of the isotropy group of $q_0 \in V_n$. It turns out that quantum mechanics on the homogeneous Riemannian manifold has a gauge structure and an isotropy group acts as the group of local gauge transformations. A gauge-fixing condition (which is necessary in this case) requires a configuration space to be extended by adding new coordinates. The quantum Lagrangian has to be modified by introducing new terms (depending on new degrees of freedom) in such a way that local gauge transformations become global ones. Obtained results are in accordance with [13].

In the third work we will consider the formulation of quantum mechanics on a Riemannian manifold with the intransitive group of isometries. In this case the number of Killing vectors is fewer than the dimension of a manifold. It will be shown that quantum dynamics is completely determined only for degrees of freedom which describe the invariant subspace (associated with Killing vectors). The other equations contain a gauge structure and the scalar “quantum potential” which indicates some arbitrariness in a theory. Formal results of this part need to be reexamined in order to establish physical meaning and to find concrete applications.

In the final (fourth) paper we will expand extended Schwinger’s quantization scheme on the case of superspace (considered as a quotient space $SP_4/\text{SO}(1, 3)$).

The investigations performed in the present serie of works shows that Schwinger’s quantization scheme, extended for the case of manifolds with a group structure (including a superspace), may be viewed as a universal method of quantum theory. This method allow one to solve the quantum mechanical problems in cases, where the canonical quantization method became questionable one, because it requires new additional assumptions.

In our opinion the approach introduced in the present works can be useful for analyses models describing the particle-like solitons in a collective coordinate formalism ([2, 3, 4]).
2 Variation principle in quantum mechanics

The variational principle, adapted for the purposes of quantum mechanics, was investigated by Schwinger in 1951 [14]. In these works Schwinger has analyzed the special case of the theory characterized by the Lagrangian with a linear kinetic part on generalized velocities \( \dot{q}^\mu : \mu = 1, n \) (here \( \{q^\mu : \mu = 1, n\} \) are generalized coordinates of the dynamical system). He has showed that the Heisenberg equations of motion and commutation relations consistent with them can be obtained within the framework of a unique scheme.

Schwinger’s quantization approach is based on the assumption about the existence of the hermitan operator of the action functional \( S[q, \dot{q}] \). Using this functional the variation of the propagator, caused by the infinitesimal unitary transformation of the complete set of commuting observables \( \{\alpha\} \) can be defined as

\[
\delta \langle \alpha_1, t_1 | \alpha_2, t_2 \rangle = \frac{i}{\hbar} \langle \alpha_1, t_1 | \delta S[q, \dot{q}] | \alpha_2, t_2 \rangle ,
\]

where \( |\alpha_1,2, t_1,2\rangle \) are initial and final states of the dynamical system (i.e. eigenvectors of operators of the complete set \( \{\alpha\} \) for the moments of time \( t_1,2 \)). The variation of the action functional \( S[q, \dot{q}] \) satisfies the relation

\[
\delta S[q, \dot{q}] = G(t_2) - G(t_1)
\]

where \( G = G(t) \) is the hermitan generator of a unitary transformation.

As far as the variation of the action functional is completely determined by the variations of generalized coordinates \( \{q^\mu\} \) and time \( t \), the condition (2.2) establishes the connection between the infinitesimal unitary transformation in (2.1) and variations \( \delta q \) and \( \delta t \). Variations that satisfy the equation (2.2) are called permissible variations.

Taking into account (2.1), (2.2) and the unitary nature of permissible variations one can make a conclusion that the variation \( \delta A \) of an arbitrary operator \( A \), caused by variations \( \delta q, \delta t \) is determined by the following expression

\[
\delta A = \frac{1}{i\hbar} [A, G]
\]

As far as in (2.3) \( \delta A \) and \( G \) contain variations \( \delta q, \delta t \), this relation can be interpreted by two ways. If the commutation relations of the model are known, one can find the explicit form of the variations \( \delta q, \delta t \) from (2.3). On the other hand, if \( \delta q \) and \( \delta t \) are given, the relation (2.3) can be viewed as the condition that determines the algebra of the commutation relations of a model. In Schwinger’s quantization scheme one use exactly the second variant of the interpretation of the relation (2.3).

Further we extend Schwinger’s quantization scheme for the case of a non-linear stationary model, in which the kinetic part of the action depends not only on velocities \( \{\dot{q}^\mu : \mu = 1, n\} \), but also on coordinates \( \{q^\mu : \mu = 1, n\} \). This fact necessarily causes an operator ordering problem in the Lagrangian which contains non-commutative operators \( q \) and \( \dot{q} \). The Lagrangian determines the action as

\[
S[q, \dot{q}] = \int_{t_1}^{t_2} L(q, \dot{q}) \, dt
\]

\(^1\) Permissible variations are called elementary (or c-number) ones if they commute with all the operators of a model. An elementary variation is equivalent to the unit operator. In [14] Schwinger has considered the model with elementary variations as permissible ones.
The action functional (2.4) is a starting conception in Schwinger’s scheme. To investigate the physical meaning of the theory based on the action (2.4) with a given Lagrangian one should make some a priori assumptions about the properties of operator variables $q$ and $\dot{q}$ (see section 4 for further discussion).

To determine the form of the generator $G = G(t)$ of a unitary transformation let us consider the special case of the coordinate transformation

$$\bar{q}(t) = q(t) + \delta q(t)$$

(2.5)

According to the properties of canonical transformations, the Lagrangian can be expressed in terms of kinetic and dynamic parts

$$L = L_{\text{kin}} - H$$

(2.6)

The variation of the kinetic part under the transformation (2.5) $L_{\text{kin}}$ satisfies the condition

$$\delta L_{\text{kin}} = - \frac{dK}{dt}$$

(2.7)

where $K = K(q, \dot{q}, \delta q)$ is some homogeneous function of $\{\delta q^\mu\}$. Hence

$$\delta L = - \frac{dK}{dt} - \delta H$$

(2.8)

Taking into account the operator equation (2.3), we can rewrite (2.6)-(2.8) in the following form

$$\delta L = - \frac{dK}{dt} - \frac{1}{i\hbar} [H, G] = - \frac{dK}{dt} + \frac{dG}{dt}$$

(2.9)

On the other hand, the variation of $L$ under the transformation (2.5) can be expressed by a standard way (by extracting a total time derivative) as

$$\delta L = \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}^\mu} \right) \star \delta q^\mu + \frac{\delta L}{\delta q^\mu} \star \delta q^\mu$$

(2.10)

where the objects

$$\frac{\partial L}{\partial \dot{q}^\mu} \star \delta q^\mu := \mathcal{P}(q, \dot{q}, \delta q), \quad \frac{\delta L}{\delta q^\mu} := \mathcal{E}(q, \dot{q}, \delta q)$$

(2.11)

denote homogeneous of $\delta q$ functions. The symbol “$\star$” is used for the sake of visuality, in the classical limit $\hbar \to 0$ the combinations (2.11) become the product of the classical moment with $\delta q$ and contraction of the Euler-Lagrange equations with $\delta q$ correspondingly 2.

Comparing (2.9) with (2.10) we obtain

2 When $f = f(q)$ and $[q^\mu, \dot{q}^\nu] \neq 0$ one cannot write down the variation $\delta f$ in the explicit form in a general case. To demonstrate what the symbol “$\star$” means, let us consider the simplest case $f(q) = q^1 q^2 q^3$. Then

$$\delta f(x) = \delta q^1 q^2 q^3 + q^1 \delta q^2 q^3 + q^1 q^2 \delta q^3 := \frac{\partial f}{\partial q^\mu} \star \delta q^\mu,$$

where

$$\frac{\partial f}{\partial q^1} = q^2 q^3, \quad \frac{\partial f}{\partial q^2} = q^1 q^3, \quad \frac{\partial f}{\partial q^3} = q^1 q^2.$$
\[
\frac{dG}{dt} = \frac{d}{dt} \left( K + \frac{\partial L}{\partial \dot{q}^\mu} \delta q^\mu \right) + \frac{\delta L}{\delta q^\mu} \delta q^\mu.
\]

(2.12)

Since (2.12) must be agreed with (2.2) we can write

\[
G = K + \frac{\partial L}{\partial \dot{q}^\mu} \delta q^\mu, \quad \frac{\delta L}{\delta q^\mu} \delta q^\mu = 0.
\]

(2.13)

The first expression in (2.13) gives the definition of a generator \(G\), the second one is related to dynamical equations for operators \(q^\mu\) in the Euler-Lagrange form.

Further development of a theory requires the explicit form of the Lagrangian and investigation of the transformation properties of operators.

### 3 Transformation Properties of Operators

The construction of the quantum mechanics for the present model is essentially based on the assumption that the coordinate operators \(\{q^\mu : \mu = 1, \ldots, n\}\) form the complete set of commuting observables. If the complete set is replaced to another one consisted with the initial set (i.e. the operators of the new set are the functions of operators from the old one), the physical meaning of a theory does not change. In particular, when the complete set is identified with coordinate operators \(\{q^\mu\}\), such a change of the complete set is nothing but the coordinate transformation \(q^\mu \rightarrow \bar{q}^\mu := \bar{q}^\mu(q)\). All the geometrical objects, which are functions of only \(\{q^\mu\}\)'s commute with them.

In this paper we assume \([q^\mu, \dot{q}^\nu] = 0\) to be a function of only \(\{q^\mu\}\)'s. This assumption can be motivated as follows. The model have to be invariant under an arbitrary (smooth) coordinate transformation \(q \rightarrow \bar{q} = \bar{q}(q)\), which is associated with the change of the set of commuting observables. To obtain the Lagrangian \(L(q, \dot{q})\) in a new coordinate system we have to make a substitution \(q = q(q'), \dot{q} = \dot{q}(q, \bar{q})\), where \(\bar{q} = d[q(q)]/dt\). The important expression \(\bar{q}^\mu = q^\mu \circ \partial_\alpha \bar{q}^\alpha(q)\) holds if and only if \([q^\mu, q^\nu] = 0\) and \([q^\mu, \dot{q}^\nu] = \{\text{some function of } q\}\) (see appendix).

Therefore, this assumption provides us to analyze a general situation, where the form of the metric tensor and coordinate transformation is not detailed. Of course, after determining the commutation relations, one have to verify its correspondence with the basic assumptions.

The transformation rule of a geometrical object under a point coordinate transformation \(q^\mu \rightarrow \bar{q}^\mu := \bar{q}^\mu(q)\) depends on its operator properties and inner structure. In this section we extend the classical definitions of a scalar, a vector and a tensor for the case of non-commutative operators.

A quantum scalar we treat as a quantum geometrical object, which doesn’t change its value under the coordinate transformation

\[
\bar{f}(\bar{q}) = f(q)
\]

(3.14)

(here the argument in brackets points to the method of description, not to the functional dependence in general).

A quantum vector is a quantum geometrical object with one index which transforms under the coordinate transformation by one of the following rules:

1. \(A^\mu(\bar{q})\) is a left-side vector, if

\[
\bar{A}^\mu(\bar{q}) = \bar{A}^\mu(\bar{q}) A^\nu(q), \quad \{\bar{A}^\mu(\bar{q}) = a^\nu(q) A^\nu(q)\}.
\]

(3.15)
2. $A^\mu (A_\mu)$ is a right-side vector, if
\[
\overline{A^\mu(q)} = A^\nu(q) \overline{A_\nu(q)}, \quad (\overline{A_\mu(q)} = A^\nu(q) a^\mu_\nu(q));
\] (3.16)

3. $A^\mu (A_\mu)$ is a two-side vector, if it is a left- and right-side vector simultaneously
\[
\overline{A^\mu(q)} = A^\nu(q) \overline{A_\nu(q)} = A^\nu(q) a^\mu_\nu(q), \quad (\overline{A_\mu(q)} = A^\nu(q) a^\mu_\nu(q) = a^\nu_\mu(q) A^\nu(q))
\] (3.17)

4. $A^\mu (A_\mu)$ is a symmetrized vector, if
\[
\overline{A^\mu(q)} = \overline{A^\nu(q)} = a^\mu_\nu(q) \circ A^\nu(q), \quad (\overline{A_\mu(q)} = a^\nu_\mu(q) \circ A^\nu(q))
\] (3.18)

with the following notations
\[
a^\mu_\nu = \frac{\partial q^\mu}{\partial q^\nu}, \quad a^\nu_\mu = \frac{\partial q^\nu}{\partial q^\mu}
\] (3.19)

for transformation matrices. Here the symbol “$\circ$” denotes the symmetrized Jordan product.

The transformation laws described by (3.15) and (3.16) correspond to non-hermitian operators. As a two-side vector we can consider an arbitrary vector which depends on only the coordinate operators \{q^\mu\} (and commutes with the transformation matrices (3.19)). At last the transformation laws described by (3.18) correspond to hermitian operators. For example the operator of a generalized velocity $\dot{q}^\mu$ transforms as a symmetrized vector
\[
\dot{q}^\mu \rightarrow \overline{\dot{q}^\nu} = \overline{a^\nu_{\mu}} \circ \dot{q}^\nu
\] (3.20)

(we have taken into account the fact that $[q^\mu, \dot{q}^\nu]$ is a function of only \{q^\mu\}'s). Every symmetrized vector can be expressed as the sum of left and right parts (see section 3).

In the remaining part of this section we summarize some useful properties of quantum geometrical objects. Let us prove that the contraction of symmetrized and two-side tensors is a symmetrized tensor. We define the operator
\[
p_\mu := g_{\mu\nu} \circ \dot{q}^\nu,
\] (3.21)

where $g_{\mu\nu} = g_{\nu\mu}$ is a two-side tensor. In new coordinates this operator receives the form
\[
\overline{p_\mu} = \overline{g_{\mu\nu} \circ \dot{q}^\nu} = \overline{g_{\nu\mu} \circ \overline{\dot{q}^\nu}} = \left(\overline{g_{\mu\nu} \circ \overline{\dot{q}^\nu}}\right) \circ \dot{q}^\nu
\]
\[
= \left(g_{\alpha\nu} \circ a_\mu^\alpha\right) \circ \dot{q}^\alpha = \left(g_{\alpha\nu} \circ \dot{q}^\alpha\right) = a^\nu_\mu \circ p_\nu.
\] (3.22)

By a similar way one can demonstrate that
\[
\dot{q}^\mu = g^{\mu\nu} \circ p_\nu \rightarrow \overline{\dot{q}^\nu} = \overline{a^\mu_\nu} \circ \dot{q}^\nu.
\] (3.23)

When \{g_{\mu\nu}\} and \{g^{\mu\nu}\} have the sense of covariant and contravariant metric tensors respectively, (3.21)-(3.23) can be interpreted as a rule for lowering and raising of the index in quantum (symmetrized) tensors.

Similarly, the Jordan contraction (or a scalar product) of two-side and symmetrized vectors is a quantum scalar. To prove this, let us consider the symmetrized vector $p_\mu$ and the two-side vector $v^\mu$. Then

\[\text{This product is defined as } a \circ b := \frac{1}{2}(ab + ba) \text{ for arbitrary operators } a \text{ and } b. \] See appendix for its properties
\( \overline{p}_\mu \circ \overline{v}^\mu = \overline{v}^\mu \circ (a_\mu^\alpha \circ p_\alpha) = p_\alpha \circ (v_\mu \circ a_\mu^\alpha) = p_\alpha \circ v^\alpha. \) \hfill (3.24)

As to the Jordan contraction of symmetrized vectors, its properties are more complicated than previously mentioned. Generally, such objects are not quantum tensors and to determine them one has to use the explicit form of commutation relations.

Now we consider the transformation properties of commutation relations:

1. for a commutator between a quantum scalar \( f =: f(q) \) and a quantum vector \( p_\mu \) we have

\[
[\overline{f}, \overline{p}_\mu] = [f, a^n_\mu \circ p_\nu] = a^n_\mu \circ [f, p_\nu]
\]

where \([f, a^\nu_\mu] = 0\) is assumed. According to (3.14)-(3.18), this object is a quantum vector;

2. a commutator between a two-side symmetrized vectors and a quantum vector \( p_\mu \) reads

\[
[\overline{v}_\mu, \overline{p}_\nu] = [a^\mu_\alpha \circ v^\alpha_\nu, a^n_\nu \circ p_\beta] = a^n_\nu \circ [a^\mu_\alpha \circ v^\alpha_\nu + v^\alpha_\nu \circ [a^\mu_\alpha, p_\beta]]
\]

The second term in the right hand side does not have a tensor sense, therefore \([v_\mu, p_\nu]\) is not a quantum tensor;

3. for a commutator between two symmetrized vectors we write

\[
[\overline{A}_\mu, \overline{B}_\nu] = [a^\mu_\alpha \circ A^\alpha_\omega, a_\nu^\beta \circ B^\beta_\chi] = a_\nu^\beta \circ [a^\mu_\alpha \circ A^\alpha_\omega + A^\alpha_\omega \circ [a^\mu_\alpha, B^\beta_\chi] + (a^\nu_\beta \circ [a^\mu_\alpha, B^\beta_\chi]) \circ A^\alpha_\omega]
\]

Analogously to the previous, \([A_\mu, B_\nu]\) fails to be a quantum tensor due to the presence of two non-covariant tensor terms in the right hand side.

In connection with the previously considered transformation properties of quantum geometrical objects one can observe that there are some fundamental complications in the formulation of quantum mechanics on a Riemannian manifold.

Namely, the naive definition of the quantum Lagrangian for a free particle in a curved space based on the classical expression

\[
L_\alpha = \frac{1}{2} \dot{q}^\mu g_{\mu\nu}(q) \dot{q}^\nu \quad (3.25)
\]

leads one to a conclusion that the Lagrangian, being a hermitian operator, fails to be a quantum scalar (in the meaning of the definition (3.14)), i.e. \( \overline{L}_\alpha(\overline{q}) \neq L_\alpha(q) \). In the explicit form we write

\[
\overline{L}_\alpha = \frac{1}{2} \dot{q}^\mu g_{\mu\nu}(q) \dot{q}^\nu = L_\alpha + \frac{1}{4} [\dot{q}^\alpha, g_{\alpha\beta} a_\mu^\beta b^\mu] - \frac{1}{8} a_\mu^\alpha a_\nu^\beta a_{\omega} g_{\alpha\beta} b^\mu b^\nu \quad (3.26)
\]

where \( b^\mu := b^\mu(q) := [a_\mu^\alpha(q), \dot{q}^\alpha] \). Therefore, the main requirement for the Lagrangian (a scalar invariance) is violated. Note that in a classical limit second and third terms in the right hand side of (3.26) vanish, being functions of the second (or higher) order of \( \hbar \).
4 Quantum Lagrangian for Free Particle in Curved Space

Now let us concentrate our attention on the formulation of the quantum mechanics for a free particle in a Riemannian space equipped with the metric $g_{\mu\nu}(q)$. The starting step in this formulation consists of construction of the quantum Lagrangian which is invariant under the coordinate transformation $q \rightarrow \overrightarrow{q} = \overrightarrow{q}(q)$. We introduce the following form of the Lagrangian

$$L = \frac{1}{2} \dot{q}^\mu g_{\mu\nu}(q) \dot{q}^\nu - U_q(q)$$

(4.27)

where $U_q = U_q(q)$ is some function which permits the function (4.27) to be a quantum scalar under a point coordinate transformation ($U_q$ may be conditionally called as “quantum potential”). Its explicit form is unknown at this stage, because to determine it we have to use commutation relations.

For the operators of quantum mechanics described by (4.27) we make the following basic assumptions

1. $[q^\mu, q^\nu] = 0$ and $\{q^\mu : \mu = 1, n\}$ form the complete set of commuting observables;

2. $[q^\mu, \dot{q}^\nu]$ is a function of only $\{q^\mu\}$’s.

These assumptions permit us to conclude that $U_q$ is a function of only $\{q^\mu\}$’s.

Taking the total time derivative of $[q^\mu, \dot{q}^\nu] = 0$ we can see that

$$\frac{1}{i\hbar} [q^\mu, \dot{q}^\nu] = f^{\mu\nu}(q) = f^{\nu\mu}(q).$$

Note that the ordering of factors in (4.27), which satisfies the hermitan condition is not unique. We can take the expression $\dot{q}^\mu \circ (g_{\mu\nu} \circ \dot{q}^\nu)$ instead of $\dot{q}^\mu g_{\mu\nu} \dot{q}^\nu$. Such a replacement leads to another function $U_q(q)$. The scalar Lagrangian $L$ is the same (one can demonstrate this fact after determination the commutation relations).

Now we consider the transformation properties of $U_q(q)$ and $L(q, \dot{q})$ under the infinitesimal coordinate transformation $q^\mu \rightarrow q^\mu + \delta q^\mu(q)$. Taking into account the fact that under such a transformation the velocity operator and the metric change as

$$\delta_c \dot{q}^\mu = \dot{q}^\alpha \circ \partial_\alpha \delta q^\mu, \quad \delta_c g_{\mu\nu} = -g_{\mu\alpha} \partial_\nu \delta q^\alpha - g_{\alpha\nu} \partial_\mu \delta q^\alpha,$$

we can write

$$\delta_c L_o = \frac{1}{4} \left[[\partial_\alpha \delta q^\mu, \dot{q}^\alpha] g_{\mu\nu}, \dot{q}^\nu\right],$$

(4.28)

where we have used the basic assumptions.

Because the Lagrangian $L = L_o - U_q$ is a scalar, we have $\delta_c L = 0$, then

$$\delta_c U_q = \delta_c L_o = \frac{1}{4} \left[[\partial_\alpha \delta q^\mu, \dot{q}^\alpha] g_{\mu\nu}, \dot{q}^\nu\right],$$

(4.29)

This formula shows, that neither $L_o$ nor $U_q$ is a quantum scalar, this property has the combination $L = L_o - U_q$.

\footnote{The term “quantum potential” is used in several works in somewhat different meaning \cite{4}. Therefore we use this term in quotation marks.}
Further, let us write down the variation of the operator $L(q, \dot{q})$ under the alteration of its arguments:

$$\delta L(q, \dot{q}) := L(q + \delta q, \dot{q} + \delta \dot{q}) - L(q, \dot{q}).$$

(4.30)

If the variation “$\delta$” satisfies

$$\frac{d}{dt}\delta q^\alpha = \delta \dot{q}^\alpha$$

and

$$\delta g_{\mu\nu}(q + \delta q) - g_{\mu\nu}(q) = \delta q^\alpha \partial_\alpha g_{\mu\nu},$$

we obtain

$$\delta L(q, \dot{q}) = \frac{1}{2} \dot{q}^\alpha (\delta q^\alpha \partial_\alpha g_{\mu\nu} + g_{\mu\alpha} \partial_\nu \delta q^\alpha + g_{\nu\alpha} \partial_\mu \delta q^\alpha) \dot{q}^\nu + \frac{1}{4} \left[ [\partial_\alpha \delta q^\mu(q), \dot{q}^\alpha] g_{\mu\nu}, \dot{q}^\nu \right] - \delta q^\alpha \partial_\alpha U_q(q).$$

(4.31)

The Lie variation of the geometrical object $F(q)$ under the transformation $q \rightarrow q + \delta q$ is defined as

$$\delta_L F(q) = \delta_c F(q) - \delta q^\mu \partial_\mu F(q).$$

In particular, the Lie variation of the non-scalar function $U_q(q)$ has the form

$$\delta_L U_q = \frac{1}{4} \left[ [\partial_\alpha \delta q^\mu(q), \dot{q}^\alpha] g_{\mu\nu}, \dot{q}^\nu \right] - \delta q^\alpha \partial_\alpha U_q(q).$$

Hence we can rewrite (4.31) as

$$\delta L = -\frac{1}{2} \dot{q}^\mu g_{\mu\nu} \dot{q}^\nu + \delta_L U_q.$$

(4.32)

The variation $\delta(\ldots)$ is permissible, if $\delta L$ reduces to the total time derivation of some function (see section (2)). Without loss the generality we can assume that $\delta L$.

Comparing the factors corresponding to different powers of $\dot{q}$ we can find that

$$\delta_L g_{\mu\nu} = 0$$

and

$$\delta_L U_q = \frac{1}{4} \left[ [\partial_\alpha \delta q^\mu(q), \dot{q}^\alpha] g_{\mu\nu}, \dot{q}^\nu \right] - \delta q^\alpha \partial_\alpha U_q = 0.$$ (4.33)

The first equation in (4.33) means that $\{\delta q^\mu\}$ is a Killing vector for the metric $\{g_{\mu\nu}\}$. Every solution of the Killing equation $\delta_L g_{\mu\nu} = 0$ can be decomposed as $\delta q^\mu = \varepsilon^\mu \nu_a$, where $\varepsilon^\mu = const$ (an infinitesimal c-numbers) and $\{\nu_a^\mu : \mu = 1, n, a = 1, m\}$ are $m$ independent solutions of this equation.

Comparing (4.32) with the general expression of the variation of the Lagrangian we find that $\delta H = 0$ (for unknown $H$). As a consequence, the generator of permissible variations $\delta q^\mu = \varepsilon^\mu \nu_a$ takes the form

$$G = p_\mu \circ \delta q^\mu = (p_\mu \circ \nu_a^\mu) \varepsilon^\mu := \varepsilon^\mu p_a$$

$$p_a := p_\mu \circ \nu_a^\mu, \quad p_\mu = g_{\mu\nu} \circ \dot{q}^\nu$$

(4.34)
where the permissible variations $\delta q^\mu = \varepsilon^a v_a^\mu$ are Killing vectors expressed as the linear combination of the independent solutions $\{v_a\}$ of the equations $\delta L g_{\mu\nu} = 0$.

Therefore we conclude that the features of quantum mechanics on a curved space $V_n$ essentially depend on the properties of its group of isometries. This group appears in a theory in the generator $G(t)$. The group properties of $\{v_a^\mu\}$ are expressed as

$$v_a^\mu \partial_\mu v_b^\nu - v_b^\mu \partial_\mu v_a^\nu = c_{ab}^c v_c^\nu$$

where $c_{ab}^c$ are the structure constants of a group. The set of vector fields $\{v_a^\mu \partial_\mu\}$ forms the representation of the Lie algebra induced by the representation of the Lie group of isometries.

On the other hand, the variation $\delta L$ can be rewritten as

$$\delta L = \frac{d}{dt}(G) - \dot{p}^\mu \circ \delta q^\mu + \frac{1}{2} \dot{q}^\mu (\delta q^a \partial_a g_{\mu\nu}) \dot{q}^\nu - \delta q^\mu \partial_\mu U_q + \frac{1}{2}[\delta q^\mu, \dot{g}_\mu]$$

where

$$g_\mu = \frac{1}{2}[\dot{q}^\nu, g_{\mu\nu}]$$

When the symbol $\delta(\ldots)$ corresponds to the permissible variations this equation falls into two equations: the first one, that describes the conservation if the generator

$$\frac{d}{dt} G = 0,$$

and the second one, that contains the equations of motion:

$$\dot{p}^\mu \circ \delta q^\mu = \frac{1}{2} \dot{q}^\mu (\partial_a g_{\mu\nu} \delta q^a) \dot{q}^\nu - \delta q^\mu \partial_\mu U_q + \frac{1}{2}[\delta q^\mu, \dot{g}_\mu]$$

In order to eliminate $\delta q^\mu$ we have to use the canonical commutation relations (unknown at this stage).

At the end of this section we point out the fact that then for an arbitrary operator $A$ we can write

$$\delta \frac{dA}{dt} = \frac{1}{i\hbar} \left[ \frac{dA}{dt}, G \right] = \frac{1}{i\hbar} \frac{d}{dt} [A, G] - \frac{1}{i\hbar} \left[ A, \frac{dG}{dt} \right] = \frac{d\delta A}{dt}$$

i.e. total time derivation commutes with the operation “$\delta$” of permissible variations.

## 5 Commutation Relations in Case of Simply Transitive Group

In the present paper we will consider the simplest case of quantum mechanics on a curved space. Namely, we restrict the group of isometries of $V_n$ to be a simply transitive transformation group on $V_n$. Such a simplification permits commutation relations to be directly determined from (2.3).

It is important to point out here that due to $U_q = U_q(q)$ this function does not make any contribution into the generator. Therefore the explicit form of $U_q$ is not required in this section. Moreover, it can be calculated when the commutation relations are given.
In the case of the simply transitive group acting on $V_n$ the number of independent Killing vectors equals to the dimension of $V_n$, i.e. $m = n$ and $\text{Rg}(v^\mu_a) = n$. Then we can introduce the inverse of $\{v^\mu_a\}$ as

$$e^a_\mu v^\nu_a = \delta^\nu_\mu, \quad e^a_\mu v^\mu_b = \delta^a_b$$

which obeys the Maurer-Cartan equation

$$\partial_\mu e^a_\nu - \partial_\nu e^a_\mu = -\epsilon^{abc} e^b_\mu e^c_\nu$$

To determine commutation relations we use (2.3). The symbol $\delta$ corresponding to the permissible variations in our case means the shift

$$\delta F(q, \dot{q}) = F(q + \delta q, \dot{q} + \delta \dot{q}) - F(q, \dot{q}),$$

for any operator $F(q, \dot{q})$. Such a variation corresponds to a unitary transformation that acts on different objects equally.

At first let us employ this relation for coordinate operators:

$$\delta q^\mu = \frac{1}{i\hbar} [q^\mu, G]$$

(5.39)

Using the explicit form of the generator of permissible variations (4.34) and $\delta q^\mu = \varepsilon^a v_a^\mu$ due to the arbitrariness of c-number parameters $\{\varepsilon^a\}$ we obtain from (5.39)

$$\left( \delta^\nu_\mu - \frac{1}{i\hbar} [q^\mu, p_\nu] \right) \circ v^\nu_a = 0$$

(5.40)

Multiplying (5.40) on the inverse matrix $\{e^a_\nu\}$ we obtain the following commutation relation

$$[q^\mu, p_\nu] = i\hbar \delta^\mu_\nu$$

(5.41)

Further let us consider the operator equation

$$\delta p_\mu = \frac{1}{i\hbar} [p_\mu, G]$$

(5.42)

Under the transformation $q \rightarrow q + \delta q(q)$ the symmetrized vector $p_\mu$ changes as

$$\delta p_\mu = -\frac{\partial \delta q^\nu}{\partial q^\mu} \circ p_\nu$$

By making use of this relation and (5.42) one easily finds

$$[p_\mu, p_\nu] \circ v^\nu_a = 0$$

(5.43)

Multiplying (5.43) on the inverse matrix $\{e^a_\mu\}$ we have

$$[p_\mu, p_\nu] = 0$$

(5.44)

Therefore, the commutation relations (5.41) and (5.44) correspond to canonical commutation relations for the canonical momentum $p_\mu$ conjugate to the coordinate $q^\mu$. The other commutation relations of the theory can be calculated using (5.41) and (5.44). In particular, (5.42) is equivalent to
\[ [q^\mu, \dot{q}^\nu] = i\hbar g^{\mu\nu}. \]  

We can observe that the basic assumption about the commutator \([q^\mu, \dot{q}^\nu]\) is in accordance with (5.37). For an arbitrary two-side geometrical object \(F = F(q)\) we have

\[ [F, p_\mu] = i\hbar \partial_\mu F \]  

For example let us consider the commutation relation between the current operators \(p_a := p_\mu \circ v_\mu^a\) (which are quantum scalars according to (3.24)). A direct calculation using (5.41), (5.44) and (4.35) leads to

\[ [p_a, p_b] = -i\hbar c^{ab} \]  

Now we discuss the transformation properties of commutation relations under a coordinate transformation. Obviously, the following commutation relation can be carried out for any two-side geometrical object \(F = F^A(q)\), where \(A = \{\alpha_1, \ldots, \alpha_k\}\) is a multiindex:

\[ \left[ F^A, p_\mu \right] = i\hbar \partial_\mu F^A \]  

In new coordinates \(F^A\) and \(p_\mu\) take the form

\[ \overline{p}_\mu = a^\nu_\mu \circ p_\nu, \quad \overline{F}^A = \overline{a}^A_B F^B \]  

where

\[ \left[ F^A, a^\nu_\mu \right] = 0, \quad \overline{a}^A_B = \overline{a}^{\beta_1}_{\beta_1} \cdots \overline{a}^{\beta_k}_{\beta_k} \]

Then

\[ \left[ \overline{F}^A, \overline{p}_\mu \right] = \left[ \overline{a}^A_B F^B, a^\nu_\mu \circ p_\nu \right] = i\hbar a^\nu_\mu \partial_\nu \left( \overline{a}^A_B F^B \right) = i\hbar \overline{\partial}_\mu \overline{F}^A \]  

This result shows that all commutation relations are form invariant under a general coordinate transformation. Therefore, the procedure of determination of the commutation relations is self-consistent.

### 6 Determination of Quantum Correction

To derive the quantum Lagrangian of a free particle in a curved space it is necessary to find the quantum correction \(U_q\). Our procedure of its determination is based on the construction of the invariant norm of a quantum vector.

In the case of a two-side vector \(\{A^\mu\}\) a norm has the following form

\[ (A, A) = \| A \|^2 := A_\mu g^{\mu\nu} A_\nu = A^\mu g_{\mu\nu} A^\nu. \]  

If the quantum vector \(\{A^\mu\}\) does not commute with \(q^\mu\), the expression (6.51) fails to be a quantum scalar according to section 4.

To extend the expression (6.51) for the case of a symmetrized vector let us consider the transformation law of \(p_\mu\) under a general coordinate transformation:

\[ \overline{p}_\mu = a^\nu_\mu \circ p_\nu = a^\nu_\mu p_\nu - \frac{i\hbar}{2} \partial_\nu a^\nu_\mu \]
or

\[ \overline{\nabla}_\mu = a^\nu_\mu \circ p_\nu = p_\nu a^\nu_\mu + \frac{i\hbar}{2} \partial_\nu a^\nu_\mu \]  \(6.53\)

The contracted Christoffel symbol \( \Gamma_\mu := \Gamma^\alpha_\mu_\alpha \) transforms as

\[ \Gamma_\mu = a^\nu_\mu \Gamma_\nu + \partial_\nu a^\nu_\mu \]  \(6.54\)

We define two non-hermitan operators

\[ \pi_\mu := p_\mu + \frac{i\hbar}{2} \Gamma_\mu, \quad \pi^\dagger_\mu := p_\mu - \frac{i\hbar}{2} \Gamma_\mu \]  \(6.55\)

with the following properties:

\[
\begin{align*}
(\pi_\mu)^\dagger &= \pi^\dagger_\mu, & (\pi^\dagger_\mu)^\dagger &= \pi_\mu, & p_\mu &= \frac{1}{2}(\pi_\mu + \pi^\dagger_\mu) \\
[\pi_\mu, \pi_\nu] &= 0, & [\pi^\dagger_\mu, \pi^\dagger_\nu] &= 0, & [\pi_\mu, \pi^\dagger_\nu] &= i\hbar \partial_\mu \Gamma_\nu = i\hbar \partial_\mu \Gamma_\nu
\end{align*}
\]  \(6.56\)

Using (6.54)-(6.56) one can observe that \(\pi_\mu\) and \(\pi^\dagger_\mu\) behave under the coordinate transformation as left-side and right-side quantum vectors correspondingly:

\[ \pi_\mu = a^\nu_\mu \pi_\nu, \quad \pi^\dagger_\mu = \pi^\dagger_\nu a^\nu_\mu. \]  \(6.57\)

Taking into account the transformation laws of \(\pi_\mu\) and \(\pi^\dagger_\mu\) we introduce the quantum norm of the symmetrized vector \(p_\mu\) as

\[ (p, p) = \|p\|^2 := \pi^\dagger_\mu g^\mu_\nu \pi^\nu. \]  \(6.58\)

Similarly, one can define two non-hermitan operators connected with \(\dot{q}^\mu\):

\[ V^\mu := \dot{q}^\mu - \frac{i\hbar}{2} \Phi^\mu, \quad V^\mu_{\dagger} := \dot{q}^\mu + \frac{i\hbar}{2} \Phi^\mu \]  \(6.59\)

with the following transformation properties

\[ \overline{\nabla}^\mu = \overline{\alpha}^\mu_\nu V^\nu, \quad \overline{\nabla}^\mu_{\dagger} = V^\nu_{\dagger} \overline{\alpha}_\nu^\mu, \]  \(6.60\)

where \(\Phi^\mu := g^{\alpha\beta} \Gamma^\mu_{\alpha\beta}\).

Due to (6.60) we introduce the quantum norm of the symmetrized vector \(\dot{q}^\mu\) as

\[ (\dot{q}, \dot{q}) = \|\dot{q}\|^2 = V^\mu_{\dagger} g^\mu_\nu V^\nu. \]  \(6.61\)

Further, taking into account the connection \(p_\mu = g^\mu_\nu \circ \dot{q}^\nu\) one can directly prove

\[ (p, p) = (\dot{q}, \dot{q}) \]  \(6.62\)

i.e. introduced above quantum norms of velocity and the momentum operators have the same value, as it must be.

These properties lead the Lagrangian to be written in the following form

\[ L = \frac{1}{2} (\dot{q}, \dot{q}) \]  \(6.63\)

Rewriting this relation using (6.59) and (6.60) we find the explicit form of \(U_q\)
\[ U_q = -\frac{\hbar^2}{4} \left( \partial_\mu \Gamma^\mu + \frac{1}{2} \Gamma^\mu _\mu \right) - \frac{\hbar^2}{4} \left( \partial_\mu \Theta^\mu - \frac{1}{2} \Theta_\mu \Theta^\mu \right) \] (6.64)

where

\[ \Gamma^\mu = g^{\mu\nu} \Gamma^\nu, \quad \Theta^\mu := \partial_\nu g^{\mu\nu}, \quad \Theta_\mu = g_{\mu\nu} \Theta^\nu \] (6.65)

and

\[ \Gamma^\mu + \Theta^\mu + \Phi^\mu = 0. \]

We also can write (6.64) as

\[ U_q = \frac{\hbar^2}{4} \left( \partial_\mu \Phi^\mu + \frac{1}{2} g_{\mu\nu} \Phi^\mu \Phi^\nu + \Gamma^\mu \Phi^\mu \right). \] (6.66)

Using commutation relations it is easy to derive the useful identity

\[ p_\mu g^{\mu\nu} p_\nu = \dot{q}^\alpha g_{\alpha\beta} \dot{q}^\beta + \frac{\hbar^2}{2} \left( \partial_\mu \Theta^\mu - \frac{1}{2} \Theta_\mu \Theta^\mu \right) \] (6.67)

Taking into account (6.67) one can rewrite (6.63) as

\[ L = \frac{1}{2} p_\mu g^{\mu\nu} p_\nu + \frac{\hbar^2}{4} \left( \partial_\mu \Gamma^\mu + \frac{1}{2} \Gamma^\mu _\mu \right). \] (6.68)

The form of the Lagrangian (6.68) as far as the expression for the norm of the quantum vector \( \dot{q} \) is fixed by the commutation relations. The choice of the definitions (6.61) and (6.68) is motivated by their similarity to classical expressions that contain geometrical objects, derived from the metric \( g_{\mu\nu} \) and operators \( q, \dot{q} \).

In order to construct the Hamiltonian of a free particle in a curved space we consider the quantum version of the Legendre transformation

\[ H = p_\mu \star \dot{q}^\mu - L \] (6.69)

where

\[ p_\mu \star \dot{q}^\mu := \frac{1}{2} \left( \pi_\mu ^\dagger V^\mu + V^{\mu \dagger} \pi_\mu \right) = (p, p) \] (6.70)

is a scalar.

From (6.69) and (6.70) we directly obtain

\[ H = (p, p) - L = \frac{1}{2} (p, p) = L \] (6.71)

So, our Lagrangian is purely kinematic.

The Hamiltonian can be rewritten in another form which is similar to a classical one:

\[ H = p_\mu \circ \dot{q}^\mu - L - Z \] (6.72)

where \( Z \) is an auxiliary variable has been introduced by Sugano [1]

\[ Z = -\frac{\hbar^2}{4} R + \frac{\hbar^2}{4} g^{\alpha\beta} \Gamma^\mu _\alpha \Gamma^\nu _\mu \beta. \] (6.73)

Here \( R \) is the scalar curvature of \( V_n \).
As a result, we have defined all the objects appearing in quantum mechanics with the simply transitive transformation group of isometries.

7 Equations of Motion

Now we rewrite the form of the Euler-Lagrange equations obtained in section 5 (see (4.37)) as the following variational equation

$$
\delta L = \left. \frac{d}{dt} \left( p_\mu \circ \delta q^\mu \right) \right| \delta q^\mu + \frac{1}{2} \dot{q}^\alpha (\delta q^\alpha \partial_\alpha g_{\mu\nu}) \dot{q}^\nu - \delta q^\mu \partial_\mu U_q + \frac{1}{2} [\delta q^\mu, \dot{g}_\mu] \tag{7.74}
$$

where

$$
g_\mu = \frac{1}{2} [\dot{q}^\nu, g_{\mu\nu}] \tag{7.75}
$$

From (7.74) one can draw a conclusion that the generator of canonical variations is $G = p_\mu \circ \delta q^\mu$ and the equations of motion are contained in the relation

$$
\dot{p}_\mu \circ \delta q^\mu = \frac{1}{2} \dot{q}^\alpha (\partial_\alpha g_{\mu\nu}) \dot{q}^\nu - \delta q^\mu \partial_\mu U_q + \frac{1}{2} [\delta q^\mu, \dot{g}_\mu] \tag{7.76}
$$

Using the set of commutation relations obtained above one can transform (7.76) to the form

$$
\dot{p}_\mu \circ \delta q^\mu = f_\mu \circ \delta q^\mu + T^{\mu\nu} \delta_L g_{\mu\nu} \tag{7.77}
$$

where

$$
f_\mu = -\frac{1}{2} p_\alpha \partial_\mu g^{\alpha\beta} p_\beta - \frac{\hbar^2}{4} \partial_\mu \left( \partial_\alpha \Gamma^\alpha + \frac{1}{2} \Gamma_\alpha \Gamma^\alpha \right) , \tag{7.78}
$$

where $T^{\mu\nu} = T^{\mu\nu}(q) \sim \hbar^2$ is some tensor of second rank. The variation $\delta q^\mu$ is a Killing vector, therefore the second term in (7.78) vanishes due to the condition $\delta_L g_{\mu\nu} = 0$. Using the decomposition $\delta q^\mu = \varepsilon^\mu v_a^\mu$ we can write (7.77) as

$$
(\dot{p}_\mu - f_\mu) \circ v_a^\mu = 0. \tag{7.79}
$$

As far as the matrix $\{v_a^\mu\}$ is invertible and describes a two-side vector, we can eliminate it from (7.79) by multiplication on its inverse $\{v_a^\mu\}$. Finally, we obtain the equation of motion in the following form

$$
\dot{p}_\mu = -\frac{1}{2} p_\alpha \partial_\mu g^{\alpha\beta} p_\beta - \frac{\hbar^2}{4} \partial_\mu \left( \partial_\alpha \Gamma^\alpha + \frac{1}{2} \Gamma_\alpha \Gamma^\alpha \right) \tag{7.79}
$$

The equation of this type was considered in [1] from the view of canonical quantization approach.

It is easy to prove that the equation (7.79) obtained from the action principle is equivalent to the Heisenberg equations

$$
\dot{p}_\mu = \frac{1}{i\hbar} [p_\mu, H] , \quad H = \frac{1}{2} (p, p) = \frac{1}{2} (\dot{q}, \dot{q}) = L. \tag{7.80}
$$

The generator $G = p_\mu \circ \delta q^\mu$ conserves due to (7.79), i.e. $\dot{G} = 0$. This fact confirms that our quantization scheme is self-consistent.
8 Hamiltonian as Generator of Time Shifts

Let us consider the coordinate transformation \( q \to q + \delta q \) caused by the infinitesimal time shift \( t \to t + \delta t(t) \).

\[
\begin{align*}
\delta q^\mu &= \dot{q}^\mu \delta t \\
\delta \dot{q}^\mu &= \frac{d}{dt} \delta q^\mu - \dot{q}^\mu \frac{d}{dt} \delta t.
\end{align*}
\] (8.81)

Using the commutation relations for the dynamical variables \( \{q^\mu\} \) and \( \{\dot{q}^\mu\} \), we obtain the following operator properties of the variations (8.81)

\[
[\dot{q}^\mu, \delta q^\nu] = [\dot{q}^\mu, \dot{q}^\nu] \delta t = [\delta q^\mu, \dot{q}^\nu];
\] (8.82)

\[
[q^\mu, \delta q^\nu] = [q^\mu, \dot{q}^\nu] \delta t = i\hbar g^{\mu\nu} \delta t.
\] (8.83)

The variation of the Lagrangian \( L \) caused by these variations equals to

\[
\delta_t L = \delta L + L \delta t.
\] (8.84)

It is easy to rewrite (8.84) as a total time derivative without any referring to equations of motion (i.e. by a purely algebraic way with the use of (8.81)):

\[
\delta_t L = \frac{d}{dt}(L \delta t).
\] (8.85)

This fact leads the variations (8.81) to be permissible ones.

Further we transformate (8.84) using explicitly the dynamical equations obtained above. By extracting a total time derivative we can write

\[
\delta_t L = \frac{d}{dt}(L \delta t) + \frac{dL}{dt} \delta t - (\dot{p}_\mu - f_\mu) \circ \delta q^\mu.
\] (8.86)

The last term in (8.86) contains the dynamical equations (7.79). Comparing (8.84) with (8.86) we can observe that

\[
\frac{dH}{dt} \delta t = 0, \quad H = L.
\] (8.87)

Therefore the Hamiltonian of our model is the conserved generator of time shifts.

9 Hilbert Space of States

Let the coordinate operators \( \{q^\mu\} \) form the complete set of commutative observables. We define it’s spectrum by the equation

\[
\hat{q}^\mu |q\rangle = q^\mu |q\rangle
\] (9.88)

(to avoid a confusion we write an operator with the hat and c-number without it in this formula and in similar cases below).

The eigenvectors of \( \{q^\mu\} \) are normalized by the following condition
\[ \langle q'' | q' \rangle = \frac{1}{\sqrt{g(q''')}} \delta(q'' - q') := \Delta(q'' - q'). \] (9.89)

Here \( \Delta(q) \) is the \( \delta \)-function on \( V_n \) conformed to the volume element \( dV = \sqrt{g(q)}dq, \ dq = dq^1 \ldots dq^n \). This function has the following properties:

\[
\int F(q') \Delta(q' - q)dq = F(q)
\]
\[
\frac{\partial \Delta(q' - q)}{\partial q^\mu} = -\Gamma^\mu_{\nu \lambda}(q') \Delta(q' - q) - \frac{\partial \Delta(q' - q)}{\partial q^\mu}
\] (9.90)

\[
(F(q') - F(q)) \Delta(q' - q) = 0
\]
\[
(F(q') - F(q)) \frac{\partial \Delta(q' - q)}{\partial q^\mu} = -\frac{\partial F(q')}{\partial q^\mu} \Delta(q' - q)
\] (9.91)

for an arbitrary smooth function \( F(q) \) on \( V_n \).

To construct a coordinate representation associated with the complete set \( \{q^\mu\} \) we need the matrix elements of acting operators. For the coordinate operator \( q^\mu \) we easily find

\[
\langle q''| q^\mu | q' \rangle = q''^\mu \langle q'' | q' \rangle.
\] (9.92)

In order to calculate the matrix element of the momentum operator let us consider the matrix element of the commutator \([q^\mu, p_\nu] = i\hbar \delta^\mu_\nu\):

\[
\langle q''| q^\mu p_\nu - p_\nu q^\mu | q' \rangle = i\hbar \delta^\mu_\nu \Delta(q'' - q').
\] (9.93)

The left hand side of the equality (9.93) can be rewritten as

\[
\langle q''| [q^\mu, p_\nu] | q' \rangle = \int dV'' \langle q''| p_\nu | q'''' \rangle \langle q''''| q''| p_\nu | q' \rangle - \langle q''| p_\nu | q'''' \rangle \langle q''''| q''| q''''| p_\nu | q' \rangle)
\]
\[
= \int dV'' \langle q''''| \Delta(q'''' - q'') | q''| p_\nu | q' \rangle - q''^\mu \Delta(q'''' - q') \langle q''''| p_\nu | q'''' \rangle
\]
\[
= (q''''^\mu - q''^\mu) \langle q''''| p_\nu | q'''' \rangle.
\]

So that (9.93) is equivalent to

\[
(q''''^\mu - q''^\mu) \langle q''''| p_\nu | q'''' \rangle = i\hbar \delta^\mu_\nu \Delta(q'''' - q').
\] (9.94)

The formula (9.94) can be viewed as the equation for unknown \( \langle q''''| p_\nu | q'''' \rangle \). Using the properties of the \( \Delta \)-function we obtain the solution of (9.94) in the form

\[
\langle q''''| p_\mu | q' \rangle = -i\hbar \frac{\partial}{\partial q''''^\mu} \Delta(q'''' - q') + F_\mu(q) \Delta(q'''' - q')
\] (9.95)

where \( F_\mu(q) \) is some smooth function on \( V_n \) which will be determined later. Its appearance in (9.93) does not lead to any inner contradictions. To observe it let us calculate the matrix element of the commutator \([f, p_\mu] \) for some operator \( f \) using (9.92), (9.93) and (9.94)-(9.94). We find:
\langle q'' | [f, p_\mu] | q' \rangle = (F_\mu(q') - F_\mu(q'')) \langle q'' | f | q' \rangle + i\hbar \left( \frac{\partial}{\partial q''_\mu} + \frac{\partial}{\partial q''_\nu} + \Gamma_\mu(q') \right) \langle q'' | f | q' \rangle. \quad (9.96)

For the case \([q'', f] = 0\) we have
\begin{align*}
\langle q'' | f(q) | q' \rangle &= f(q') \Delta(q'' - q'). \quad (9.97)
\end{align*}

So that (9.96) can be reduced to
\begin{align*}
\langle q'' | [f(q), p_\mu] | q' \rangle &= i\hbar \frac{\partial f(q')}{\partial q''_\mu} \Delta(q'' - q'). \quad (9.98)
\end{align*}

(using (9.90)-(9.91) and (9.97)). This result is completely agreed with the commutator
\[ [f(q), p_\mu] = i\hbar \frac{\partial f(q)}{\partial q''_\mu}. \]

Now we turn to the explicit form of the function \(F_\mu(q)\). To determine it we need the matrix element of the commutator \([p_\mu, p_\nu] = 0\) which can be obtained by replacing \(f(q)\) by \(p_\nu\) in (9.96):
\begin{align*}
\langle q'' | [p_\mu, p_\nu] | q' \rangle &= i\hbar \left( \frac{\partial F_\nu(q')}{\partial q''_\mu} - \frac{\partial F_\mu(q')}{\partial q''_\nu} \right) \Delta(q'' - q') = 0.
\end{align*}

From this equation we find
\[ F_\mu = \frac{\partial F(q)}{\partial q''_\mu}. \quad (9.99) \]

where \(F(q)\) is some scalar function. Due to (9.99) we rewrite (9.93) as
\begin{align*}
\langle q'' | p_\mu | q' \rangle &= -i\hbar \frac{\partial \Delta(q'' - q')}{\partial q''_\mu} + \frac{\partial F(q'')}{\partial q''_\mu} \Delta(q'' - q'). \quad (9.100)
\end{align*}

The Hermitian conjugation of (9.100) due to (9.90)-(9.91) can be expressed as
\begin{align*}
\langle q' | p_\mu | q'' \rangle^* &= -i\hbar \frac{\partial \Delta(q'' - q')}{\partial q''_\mu} - i\hbar \Gamma_\mu(q') \Delta(q'' - q') + \frac{\partial F^*(q'' - q')}{\partial q''_\mu}. \quad (9.101)
\end{align*}

The Hermitian property of \(p_\mu\) leads to
\[ \langle q'' | p_\mu | q' \rangle = \langle q' | p_\mu | q'' \rangle^* \]
then
\[ \text{Im} \left( \frac{\partial F}{\partial q''_\mu} \right) = \frac{1}{2i} \frac{\partial}{\partial q''_\mu} (F - F^*) = \frac{\hbar}{2} \Gamma_\mu. \quad (9.102) \]

From the definition of \(\Gamma_\mu\) we find
\[ \Gamma_\mu = \frac{1}{2} \partial_\mu \ln g \]

Therefore we can decompose \(F(q)\) into real and imagine parts
\[ F = -\varphi - \frac{i\hbar}{4} \ln g \]  

(9.103)

where \( \varphi \) is some real-valued scalar function on \( V_n \).

Using (9.103) in (9.95) we finally write the matrix element of \( p_\mu \):

\[
\langle q'' | p_\mu | q' \rangle = -i\hbar \frac{\partial}{\partial q''^{\mu}} - \left( \frac{\partial \varphi}{\partial q''^{\mu}} + \frac{i\hbar}{2} \Gamma_\mu(q'') \right) \Delta(q'' - q')
\]

(9.104)

depending on an arbitrary real-valued function \( \varphi(q) \). Its appearance in (9.104) does not affect on physical states because we can eliminate \( \varphi(q) \) by the unitary transformation

\[
|q\rangle \rightarrow U(q) |q\rangle \\
p_\mu \rightarrow U p_\mu U^\dagger = p_\mu - \partial_\mu \varphi \\
q'' \rightarrow U q'' U^\dagger = q''
\]

(9.105)

(9.106)

where

\[
U(q) = \exp \left( -\frac{1}{i\hbar} \varphi(q) \right)
\]

(see [15]). Therefore, without loss of generality we assume \( \varphi(q) = 0 \).

Now we construct the coordinate representation for our model. In order to do it we represent the wave function

\[
\psi(q) = \langle q | \psi \rangle
\]

(9.107)

for an arbitrary state \( |\psi\rangle \).

The coordinate representation of the operator \( f \) is defined by the following formula

\[
\hat{f}\psi(q) := \langle q | f \rangle |\psi\rangle = \int dq' \sqrt{g(q')} \langle q | f \rangle |q'\rangle \langle q' | \psi\rangle
\]

(9.108)

Substituting \( f = q'' \) we can obtain

\[
\hat{q}''\psi(q) = \int dq' \sqrt{g(q')} \langle q | q'' \rangle |q'\rangle \langle q' | \psi\rangle = q''\psi(q).
\]

(9.109)

Similarly, making the substitution \( f = p_\mu \) in (9.108) we write

\[
\hat{p}_\mu\psi(q) = \int dq' \sqrt{g(q')} \langle q | p_\mu \rangle |q'\rangle \langle q' | \psi\rangle
\]

\[
= \int dq' \sqrt{g(q')} \left( F_\mu(q')\Delta(q - q') - i\hbar \frac{\partial \Delta(q - q')}{\partial q''^{\mu}} \right) \psi(q)
\]

\[
= -i\hbar \frac{\partial \psi(q)}{\partial q^{\mu}} - \frac{i\hbar}{2} \Gamma_\mu(q)\psi(q) - \frac{\partial \varphi(q)}{\partial q^{\mu}} \psi(q).
\]

Taking \( \varphi(q) = 0 \) we finally have

\[
\hat{p}_\mu\psi(q) = -i\hbar \left( \frac{\partial}{\partial q^{\mu}} + \frac{1}{2} \Gamma_\mu(q) \right) \psi(q)
\]

(9.110)
This representation coincides with [16]. Under a general coordinate transformation the object (9.110) transforms as a vector.

Hence we have found the coordinate representation for coordinate and momentum operators

\[ \hat{q}^\mu = q^\mu, \quad \hat{p}_\mu = -i\hbar \left( \frac{\partial}{\partial q^\mu} + \frac{1}{2} \Gamma_\mu \right). \] (9.111)

The coordinate representation for the operators \( \pi_\mu \) and \( \pi_\mu^\dagger \) can be constructed by a similar way. Their matrix elements have the form:

\[ \langle q'' | \pi_\mu | q' \rangle = -i\hbar \frac{\partial}{\partial q''^\mu} \Delta(q'' - q') \]
\[ \langle q'' | \pi_\mu^\dagger | q' \rangle = -i\hbar \frac{\partial}{\partial q''^\mu} \Delta(q'' - q') - i\hbar \Gamma_\mu(q') \Delta(q'' - q'). \] (9.112)

Therefore,

\[ \hat{\pi}_\mu = -i\hbar \frac{\partial}{\partial q^\mu}, \quad \hat{\pi}_\mu^\dagger = -i\hbar \frac{\partial}{\partial q^\mu} - i\hbar \Gamma_\mu. \] (9.113)

In order to find the coordinate representation of the Hamiltonian, we use the formula

\[ \hat{A}(\hat{B}\psi) = \int dV' dV'' \langle q| A | q' \rangle \langle q' | B | q'' \rangle \langle q'' | \psi \rangle \]
\[ = \int dV'' \langle q | AB | q'' \rangle \langle q'' | \psi \rangle = \hat{A}\hat{B}\psi. \] (9.114)

Putting \( \hat{A} = \hat{\pi}_\mu^\dagger \), \( \hat{B} = g^\mu\nu \pi_\mu \) into (9.114) we have

\[ 2\hat{H}\psi = (\pi_\mu^\dagger g^\mu\nu \pi_\nu)^\wedge \psi = \hat{\pi}_\mu^\dagger (g^\mu\nu \hat{\pi}_\nu \psi) = -\hbar^2 \left[ \frac{\partial}{\partial q^\mu} \left( g^\mu\nu \frac{\partial \psi}{\partial q^\nu} \right) + \Gamma_\mu \left( g^\mu\nu \frac{\partial \psi}{\partial q^\nu} \right) \right] \]
\[ = -\hbar^2 \frac{1}{\sqrt{g}} \frac{\partial}{\partial q^\mu} \left( g^\mu\nu \frac{\partial \psi}{\partial q^\nu} \right) \psi = -\hbar^2 \nabla_\mu g^\mu\nu \nabla_\nu \psi. \] (9.115)

Here \( \nabla_\mu \) is covariant derivative in the metric \( \{ g_{\mu\nu} \} \).

Hence, the coordinate representation of the Hamiltonian

\[ \hat{H} = -\frac{1}{2} \hbar^2 \nabla_\mu g^{\mu\nu} \nabla_\nu \psi \] (9.116)

is nothing but the Laplace operator on \( V_n \).

The Schrödinger equation for a free particle on \( V_n \) reads

\[ -\frac{\hbar^2}{2} \frac{1}{\sqrt{g}} \frac{\partial}{\partial q^\mu} \left( g^{\mu\nu} \frac{\partial \psi}{\partial q^\nu} \right) = E \psi. \] (9.117)

In the end of this section we add a remark on the form of the generator \( G \). Using (9.114) we directly calculate

\[ \hat{G} = \hat{v}^\mu \circ \hat{p}_\mu = -i\hbar v^\mu \frac{\partial}{\partial q^\mu}; \] (9.118)

where \( \{ v^\mu \} \) is a Killing vector (note that we need the particular form of the Killing equation, namely \( \nabla_\mu v^\mu = 0 \)).
10 Conclusions

Observing obtained results, we can conclude that our extension of Schwinger’s quantization procedure allow one to solve the problem of the formulation of quantum mechanics on the manifold with a group structure without assuming non-strictly motivated assumptions.

The main features of the present work, which have a general character, are:

1. the logical motivation of the use of Killing vectors as permissible variations in quantum mechanics on the Riemannian space in Schwinger’s approach;
2. the method of construction of the Lagrangian which is invariant under a general coordinate transformation;
3. the definition of the quantum norm of velocity and momentum operators which is invariant under a general coordinate transformation.

Applying them, we have rigorously defined quantum mechanics on the manifold with the simply transitive group of isometries. The theory includes commutative relations, Lagrangian and Heisenberg equations of motion and seems to be self-consistent.

These results, obtained within the framework of a unified quantization approach, are in accordance with [1] and [16], where the quantum theory was developed by means of canonical quantization methods based on some special assumptions.

In forthcoming papers we will apply our quantization procedure to construct a quantum theory on Riemannian manifolds with a more complicated group structure.

Appendix. Summetrrized Jordan Product

When $a, b$ are hermitan operators, its product $a \cdot b$ is non-hermitan in a general case. The Hermitan condition holds for the Jordan product

$$a \circ b = \frac{1}{2} (ab + ba).$$  \hspace{1cm} (A.1)

From this definition one can immediately obtain

1. $a \circ b = b \circ a$;
2. $(a + b) \circ c = a \circ c + b \circ c$;
3. $(\alpha a) \circ b = a \circ (ab) = \alpha (a \circ b), \quad \alpha \in C$;
4. $[a, b \circ c] = [a, b] \circ c + b \circ [a, c]$;

The Jordan product is non-associative:

$$a \circ (b \circ c) = (a \circ b) \circ c - \frac{1}{4} [b, [a, c]]$$  \hspace{1cm} (A.2)

Let us concentrate our attention on the combinations appearing in our model. The basic assumptions have the form (see section (4)):

1. $\forall \mu, \nu = 1, n, \quad [g^\mu, g^\nu] = 0$,
2. $\frac{1}{\eta} [q^\mu, \dot{q}^\nu] = f^{\mu\nu}(q)$.

Taking the time derivative
\[
\frac{d}{dt} [q^\mu, q^\nu] = [\dot{q}^\mu, q^\nu] + [q^\mu, \dot{q}^\nu] + 0,
\]
we find:
\[
f^{\mu\nu}(q) = f^{\nu\mu}(q). \tag{A.3}
\]

Due to these properties, the time derivative of the operator $F(q)$ can be written as
\[
\frac{d}{dt} F(q) = \dot{q}^\mu \partial F(q) / \partial q^\mu \tag{A.4}
\]
(if $F(q)$ is a polynomial, the proof is elementary).

It is important to note that in some cases, that are determined by the operator properties of multipliers, the Jordan product is associative. Looking at the formula (A.2) we see, that $a \circ (b \circ c) = (a \circ b) \circ c$ if $[a, b] = 0$ or $[b, [a, c]] = 0$. Taking into account the basic assumptions we can write
\[
f_1(q) \circ (\dot{q}^\mu \circ f_2(q)) = (f_1(q) \circ \dot{q}^\mu) \circ f_2(q), \tag{A.5}
\]
\[
f_1(q) \circ (\dot{q}^\mu \circ f_2(q)) = f_1(q) \circ (f_2(q) \circ \dot{q}^\mu)
= (f_1(q) f_2(q)) \circ \dot{q}^\mu - \frac{1}{4} [f_2(q), \text{some function of } q^\nu] = (f_1(q) f_2(q)) \circ \dot{q}^\mu. \tag{A.6}
\]
