Ghrelin, as a kind of multifunctional protein polypeptide, is mainly produced in the fundus of the stomach and can promote occurrence and development of many tumors, including gastrointestinal tumors, which has been proved by the relevant researches. Most gastrointestinal stromal tumors (GISTs, about 80%), as the most common mesenchymal tumor, also develop in the fundus. Scientific research has confirmed that ghrelin, its receptors and mRNA respectively can be found in GISTs, which demonstrated the existence of a ghrelin autocrine/paracrine loop in GIST tissues. However, no reports to date have specified the mechanism whether ghrelin can promote the occurrence and development of GISTs. Studies of pulmonary artery endothelial cells in a low-oxygen environment and cardiac muscle cells in an ischemic environment have shown that ghrelin can activate the phosphatidylinositol 3-kinase/AKT/mammalian target of rapamycin (PI3K/AKT/mTOR) signaling pathway. Moreover, some studies of GISTs have confirmed that activation of the PI3K/AKT/mTOR pathway can indeed promote the growth and progression of GISTs. Whether ghrelin is involved in the development or progression of GISTs through certain pathways remains unknown. Can we find a new target for the treatment of GISTs? This review explores and summaries the relationship among ghrelin, the PI3K/AKT/mTOR pathway and the development of GISTs.

**Core tip:** Ghrelin has been proven to promote the occurrence and development of gastrointestinal tumors. Some gastrointestinal stromal tumors (GISTs) express ghrelin and its receptors. However, no previous reports have specified whether ghrelin is involved in the occurrence and development of GISTs. Through
a review of the literature, this paper is the first to summarize and discuss the correlation between ghrelin and GISTs.

INTRODUCTION

Gastrointestinal stromal tumors (GISTs) originate from pacemaker cells (interstitial cells of Cajal, or Cajal cells). They are the most common mesenchymal tumors in the gastrointestinal tract, with an annual incidence of approximately 10-20 per million. Although GISTs can occur in any part of the digestive tract, about 70% are found in the stomach, 10%-25% in the small intestine[1], and a small percentage in the rectum. However, GISTs rarely affect the esophagus or colon[2].

GISTs result from acquired functional changes caused by mutations in the KIT and PDGFRA genes located on chromosome 4q12. These mutations result in expression of activated forms of the protein products [c-KIT, which is a receptor tyrosine kinase (RTK), and platelet-derived growth factor receptor-α (PDGFRA)], leading to inhibition of apoptosis, activation of cell proliferation, and promotion of tumorigenesis[3,4].

At present, treatment strategies for GISTs mainly focused on the KIT and PDGFRA genes and their RTK products. Although introduction of the c-KIT and PDGFRA inhibitor imatinib (Gleevec®) has greatly improved treatment efficacy, the median progression-free survival time of patients with GISTs is only about 2 years. The incidence of secondary (acquired) drug resistance within the first 2 years of imatinib treatment is approximately 40%-50%[5]. Patients who display primary resistance to first-line therapy with imatinib can be treated with the multiple-kinase inhibitor sunitinib malate[6]. However, one trial revealed that the objective response rate to sunitinib malate was only 65% (7% partial response and 58% stable disease without progression)[7]. Moreover, the clinical effect is short and drug resistance soon appears. Therefore, although there are many advantages in the current targeted therapies for GISTs, there are also drawbacks, highlighting the urgent need for new ways to treat GISTs.

Clinical observations indicate that most GISTs originate at the base of the stomach, which is also the main secretion site of gastric ghrelin. As described in the following sections, ghrelin is a protein with a variety of functions[8]. Ghrelin receptors are expressed in several types of tumors, including gastric and colon cancer, and are able to promote tumor growth[9-11]. The Cajal cells from which GISTs arise both produce ghrelin and express the ghrelin receptor[12]. Whether ghrelin is involved in the development or progression of GISTs through certain pathways remains unknown. Can we find a new target for the treatment of GISTs? We herein review the relevant literature on this topic.

GHRELIN

Ghrelin is a 28-amino-acid peptide that also exists as des-Gln(14)-ghrelin[13-15]. Ghrelin is currently considered to be the main endogenous ligand of growth receptors[16]. The ghrelin coding gene is located on chromosome 3 (3p25-26)[17].

Approximately 80% of ghrelin in serum is produced by cells at the base of the stomach (“A-X-like” cells), most of which are distributed in acid-secreting glands[18]. These “A-X-like” cells constitute approximately 20% of gastric endocrine cells[19]. Ghrelin is also secreted by the hypothalamus, pituitary gland, kidneys[20], placenta[21], intestinal tract, thyroid[22], heart[13], Leydig cells[23], neutrophils, lungs[24,26], and ovarian tissues[26,27].

Some of the many functions of ghrelin include regulation of growth hormone secretion, energy balance, gastrointestinal motility, gastric acid secretion, cardiovascular activity, pancreatic hormone secretion, glucose metabolism, prolactin and adrenocorticotropic hormone secretion, sleep[15,23], and gonadal hormone secretion. Several studies[9-11] have shown that ghrelin can promote the development of malignant tumors through a variety of signaling pathways that increase cell proliferation and metastasis, including the phosphatidylinositol 3-kinase/AKT/mammalian target of rapamycin (PI3K/AKT/mTOR), Ras/RAF/extracellular signal-regulated kinases (ERK1/2), Janus kinase/signal-regulated kinases (ERK1/2), and Src kinase pathways.

GISTs EXPRESS GHRELIN AND GHRELIN RECEPTORS

To the best of our knowledge, the only study that has examined the expression of ghrelin and its receptors in GIST tissues is a Japanese study[28] in which ghrelin, ghrelin receptors, and their respective mRNA were detected in all 17 GIST tissues examined, although the extent of ghrelin and ghrelin receptor expression differed in each GIST tissue. The study demonstrated the existence of a ghrelin autocrine/paracrine loop in GIST tissues, suggesting that ghrelin may play a role in the occurrence and development of GISTs.

In contrast, the same study[28] found no statistically significant differences between positive ghrelin expression and tumor location (P = 0.426), tumor size (P = 0.590), KIT genotype (P = 0.935), a mitotic number of > 5 (P = 0.210), a Ki67 index of < 5 (P
ROLE OF PI3K/AKT/mTOR PATHWAY IN GISTs

RTKs such as c-KIT and PDGFRA can activate a variety of intracellular signaling pathways, such as PI3K/AKT/mTOR, Ras/RAF/ERK, JAK/STAT, and Src kinases, which can in turn activate signaling axes downstream of c-KIT. These RTKs are therefore key factors in the treatment of GISTs, especially refractory GISTs[29]. PI3K/AKT/mTOR pathway activation is associated with the development and invasion of a number of tumors[9-11]. Indeed, c-KIT activation via autophosphorylation leads to excessive activation of PI3K/AKT/mTOR, which promotes the development and progression of GISTs[29,30]. Thus, blocking excessive activation of this signaling pathway may provide a new therapeutic strategy for GISTs.

The PI3K/AKT/mTOR signaling pathway regulates cell growth, proliferation, and differentiation. The initiating signal molecule, PI3K[31], can be activated by RTKs, G protein-coupled receptors, and oncogenic Ras (Figure 1). Phosphorylation of the RTK recruits PI3K to the inner surface of the cell membrane, where it catalyzes the phosphorylation of phosphatidylinositol (4,5)-bisphosphate (PIP2) to phosphatidylinositol (3,4,5)-trisphosphate (PIP3). This reaction is reversed by phosphatase and tensin homolog (PTEN), which dephosphorylates PIP3 to PIP2[32]. Generation of PIP3 promotes translocation of the serine/threonine protein kinase AKT to the plasma membrane, and activated AKT indirectly leads to the accumulation of the Ras homology protein Rheb and activation of mTORC1[33]. mTORC1 then activates the downstream kinases S6 kinase 1 (S6K1) and S6K2, which stimulate protein synthesis, cell survival, and growth signal release[34-36].

This pathway is essential for the continued growth of tumors and it is therefore being intensely investigated as a source of new therapeutic strategies for GISTs.

The PI3K/AKT/mTOR signaling pathway is blocked by a number of inhibitors. Rapamycin derivatives such as temsirolimus, the first clinically applied inhibitor, mainly inhibit mTORC1. Dual inhibitors such as GDC-0980, BEZ235, and SFI126 inhibit PI3K and mTORC1[29], whereas BKM120 and GDC-0941 specifically inhibit PI3K but not mTOR[38]. In addition, Alkyl phosphoric acid choline compound can effectively inhibit Akt[39,40].

Studies have indicated that loss of the PTEN gene and dysregulation of the PI3K/ATK/mTOR signaling pathway may play an important role in the progression and drug resistance of GISTs. In cells
survival rate of adipose-derived mesenchymal stem cells and pulmonary artery endothelial cells exposed to hypoxia. Western blot analysis showed that ghrelin reduced expression of the pro-apoptotic protein Bax, increased the level of the anti-apoptotic protein Bcl-2, and significantly increased phosphorylation of AKT and mTOR \[44,45\]. The PI3K inhibitor LY294002 suppressed phosphorylation events, indicating that ghrelin activates the PI3K/AKT/mTOR pathway through phosphorylation. Two other studies, one examined the modulatory effect of ghrelin on gastric mucosal prostaglandin and nitric oxide and another examined gastric mucosal inflammatory responses to Helicobacter pylori \[46,47\], which showed that ghrelin activates the PI3K/AKT/mTOR pathway in different ways \[46,47\]. Whether ghrelin promotes the development and progression of GISTs through this or other mechanisms remains unclear.

CONCLUSION
GISTs express ghrelin and ghrelin receptors. Ghrelin can activate the PI3K/AKT/mTOR signaling pathway in cardiac muscle cells and pulmonary artery endothelial cells, which plays an important role in the occurrence and development of GISTs. It is possible that ghrelin may promote GISTs by activating this pathway. However, this remains to be fully elucidated.
