Abstract—The distillable entanglement of a bipartite quantum state does not exceed its entanglement cost. This well known inequality can be understood as a second law of entanglement dynamics in the asymptotic regime of entanglement manipulation, excluding the possibility of perpetual entanglement extraction devices that generate boundless entanglement from a finite reserve. In this paper, I establish a refined second law of entanglement dynamics that holds for the non-asymptotic regime of entanglement manipulation.

I. INTRODUCTION

Entanglement is a fundamental resource for quantum information processing, as it is the enabling fuel for critical protocols like teleportation [1], super-dense coding [2], and quantum key distribution [3]. As such, it has been a longstanding challenge to understand entanglement as a resource and to quantify it [4], [5], and this subject is known as entanglement theory (see [6]–[9] for reviews of the topic, as well as the latest results).

Two basic operational quantities of interest in entanglement theory are the distillable entanglement and the entanglement cost of a bipartite state $\rho_{AB}$. The physical scenario corresponding to these quantities is that Alice and Bob are in distant laboratories, a third party distributes system $A$ of $\rho_{AB}$ to Alice and system $B$ of $\rho_{AB}$ to Bob, and they are allowed to perform local operations and classical communication (LOCC) on this state. The distillable entanglement is defined to be the maximal rate at which ebits (Bell states) can be extracted from a large number $n$ of copies of $\rho_{AB}$ by means of an entanglement distillation protocol, i.e., when using LOCC for free and such that the fidelity of the actual output state to the desired ideal ebits approaches one in the limit $n \to \infty$. The entanglement cost is defined to be the minimal rate at which ebits are needed to generate a large number $n$ of copies of $\rho_{AB}$ by means of an entanglement dilution protocol, i.e., when using LOCC for free and such that the fidelity of the actual output to the ideal state $\rho_{AB}^{\otimes n}$ approaches one in the limit $n \to \infty$. Both the distillable entanglement and the entanglement cost are notoriously difficult to calculate in general, and it is even suspected that these quantities are uncomputable in the Turing sense [11].

It has long been understood that the distillable entanglement does not exceed the entanglement cost [5], [12]. This inequality can be interpreted as a “second law of entanglement dynamics,” preventing the existence of perpetual entanglement extraction devices that generate an unbounded amount of entanglement from a finite reserve. The inequality indeed follows from basic reasoning akin to that for the second law of thermodynamics and against perpetual motion machines: If the inequality were not to hold, then it would be possible to produce a boundless amount of entanglement, by repeatedly executing a protocol for entanglement distillation followed by one for entanglement dilution. This is intuitively impossible, and so the distillable entanglement cannot exceed the entanglement cost. See [13] for a formal proof and [14], [15] for a strengthened second law of entanglement dynamics that holds for free operations beyond LOCC.

The reasoning given above applies in the asymptotic regime of a large number $n$ of copies of the state $\rho_{AB}$ and with fidelities tending to one in the limit $n \to \infty$. However, this reasoning does not apply in the non-asymptotic regime of interest for practical applications and near-term quantum devices. As such, we are left to wonder what kind of relationship might hold in the non-asymptotic regime; i.e., what is a second law of entanglement dynamics for the non-asymptotic regime?

In this paper, I establish a fundamental inequality relating distillable entanglement and entanglement cost in the non-asymptotic regime (see Theorem 1), which addresses the aforementioned question. This inequality states that the one-shot distillable entanglement does not exceed the one-shot entanglement cost plus an additional finite-size correction term that depends on the errors of the transformations corresponding to distillation and dilution. In the regime in which the errors are small, this correction term is approximately linear in the total error, indicating that the one-shot distillable entanglement cannot be much larger than the one-shot entanglement cost. However, when the errors are large (i.e., near to one), the correction term can be rather large, so that the inequality is not particularly relevant. Furthermore, the asymptotic statement mentioned above is recovered from Theorem 1 by applying limits and the definitions of distillable entanglement and entanglement cost in the asymptotic regime.

The rest of this paper proceeds by establishing notation and defining the one-shot distillable entanglement and one-shot entanglement cost of a bipartite state. I then prove the main result (Theorem 1) in three parts. First, I recall that the $\varepsilon$-Rains relative entropy [18], [19] is an upper bound on the one-shot distillable entanglement [9], [20]. The second part is...
the main technical result: an exact evaluation of the $\varepsilon$-Rains relative entropy of a maximally entangled state. The third part consists of applying this identity in the analysis of a quasi-cyclic process that dilutes a maximally entangled state to a generic bipartite state and then distills that back to another maximally entangled state. After that, I show how to recover the asymptotic statement of the second law by taking limits, and I establish an alternate non-asymptotic second law when errors are measured with normalized trace distance rather than fidelity. Finally, I discuss how this inequality extends much more generally to the entanglement theory of bipartite quantum channels [21]–[25].

II. DEFINITIONS

Nearly all concepts discussed in this preliminary section are reviewed in detail in [9]. Let us begin by defining $\Phi^d_{AB}$ as the following maximally entangled state of Schmidt rank $d$:

$$\Phi^d_{AB} := \frac{1}{d} \sum_{i,j=0}^{d-1} |i\rangle_A \otimes |j\rangle_B,$$

where $\{|i\rangle_A\}$ and $\{|i\rangle_B\}$ are orthonormal bases.

A bipartite channel is an LOCC channel if it can be realized as a finite, yet arbitrarily large number of compositions of one-way LOCC channels of the following form [9], [26]:

$$\mathcal{L}^x_{AB} \rightarrow A'B' = \sum_x \mathcal{E}^x_{AB} \otimes F_{B' \rightarrow B'},$$

$$\mathcal{L}_{AB} \rightarrow A'B' = \sum_x \mathcal{G}^x_{AB} \otimes K_{B' \rightarrow B'},$$

where $\{\mathcal{E}^x_{AB}\}_x$ and $\{\mathcal{K}^x_{B' \rightarrow B'}\}_x$ are sets of completely positive maps such that the sum maps $\sum_x \mathcal{E}^x_{AB}$ and $\sum_x \mathcal{K}^x_{B' \rightarrow B'}$ are trace preserving and $\{\mathcal{F}_{B' \rightarrow B'}\}_x$ and $\{\mathcal{G}^x_{AB}\}_x$ are sets of quantum channels (i.e., completely positive, trace-preserving maps). An LOCC channel $\mathcal{L}_{AB} \rightarrow A'B'$ can be written in the following separable form:

$$\mathcal{L}_{AB} \rightarrow A'B' = \sum_y \mathcal{P}^y_{AB} \otimes Q^y_{B' \rightarrow B'},$$

where $\{\mathcal{P}^y_{AB}\}_y$ and $\{\mathcal{Q}^y_{B' \rightarrow B'}\}_y$ are sets of completely positive maps such that $\mathcal{L}_{AB} \rightarrow A'B'$ is trace preserving. However, the converse statement is not true [27]: i.e., not every channel that can be written as in (4) can be realized by LOCC.

The fidelity of quantum states $\omega$ and $\tau$ is defined as $F(\omega, \tau) := \|\sqrt{\sqrt{\omega} \tau \sqrt{\omega}}\|^2$ [28], and the trace distance as $\|\omega - \tau\|_1$, where $\|\cdot\|_1 = \text{Tr} [\sqrt{\sqrt{\cdot} \sqrt{\cdot}}]$ is the trace norm (i.e., Schatten 1-norm). The sine distance of $\omega$ and $\tau$ is defined as $P(\omega, \tau) := \sqrt{1 - F(\omega, \tau)}$ [29]–[32], and it obeys the triangle inequality, as well as the data-processing inequality $P(\omega, \tau) \geq P(N(\omega), N(\tau))$, where $N$ is a quantum channel.

The one-shot distillable measure $E_D^\varepsilon(A; B)_\rho$ of a bipartite state $\rho_{AB}$ is defined for $\varepsilon \in [0, 1]$ as [16]

$$E_D^\varepsilon(A; B)_\rho := \sup_{d \in \mathbb{N}} \inf_{\mathcal{L} \in \text{LOCC}} \{\log_2 d : F(\mathcal{L}_{AB} \rightarrow A'B(\rho_{AB}), \Phi^d_{AB}) \geq 1 - \varepsilon\}.$$

In words, it is equal to the maximum number of $\varepsilon$-approximate ebits that one can distill from $\rho_{AB}$ by means of LOCC. The one-shot entanglement cost of $\rho_{AB}$ is defined for $\varepsilon \in [0, 1]$ as [17]

$$E_D^\varepsilon(A; B)_\rho := \inf_{d \in \mathbb{N}} \inf_{\mathcal{L} \in \text{LOCC}} \{\log_2 d : F(\mathcal{L}_{AB} \rightarrow A'B(\Phi^d_{AB}), \rho_{AB}) \geq 1 - \varepsilon\}.$$

In words, it is equal to the minimum number of ebits that is required to generate $\rho_{AB}$ approximately by means of LOCC. Observe that the function $\varepsilon \rightarrow E_D^\varepsilon(A; B)_\rho$ is monotone non-decreasing while the function $\varepsilon \rightarrow E_D^\varepsilon(A; B)_\rho$ is monotone non-increasing. One can alternatively define the approximation error for $E_D^\varepsilon(A; B)_\rho$ and $E_D^\varepsilon(A; B)_\rho$ in terms of normalized trace distance instead of fidelity, which we consider later on in Section V.

III. SECOND LAW OF ENTANGLEMENT DYNAMICS IN THE NON-ASYMPTOTIC REGIME

The main result of this paper is the following inequality that relates distillable entanglement and entanglement cost in the non-asymptotic regime, interpreted as a second law of entanglement dynamics:

**Theorem 1**: Let $\rho_{AB}$ be a bipartite state, and let $\varepsilon_1, \varepsilon_2 \in [0, 1]$ be such that $\varepsilon' := \left[\sqrt{\varepsilon_1} + \sqrt{\varepsilon_2}\right]^2 < 1$. Then

$$E_D^{\varepsilon'}(A; B)_\rho \leq E_D^{\varepsilon_1}(A; B)_\rho + \log_2 \left(\frac{1}{1 - \varepsilon'}\right).$$

**Remark 1**: Given that $\log_2 \left(\frac{1}{1 - \varepsilon'}\right) = x / \ln 2 + O(x^2)$ for $x \approx 0$, the inequality in (7) asserts that the one-shot distillable entanglement is bounded from above by the one-shot entanglement cost plus a small correction term when the error sum $\varepsilon'$ is small. When the error sum $\varepsilon'$ is large (i.e., $\approx 1$), the inequality is loose and it does not exclude the possibility of the one-shot distillable entanglement exceeding the one-shot entanglement cost.

**Proof of Theorem 1** The proof involves three parts. First, let us recall that the one-shot distillable entropy $E_D^\varepsilon(A; B)_\rho$ is bounded from above by the $\varepsilon$-Rains relative entropy for all $\varepsilon \in [0, 1]$:

$$E_D^\varepsilon(A; B)_\rho \leq R_H^\varepsilon(A; B)_\rho,$$

where the $\varepsilon$-Rains relative entropy is defined as [18], [19]

$$R_H^\varepsilon(A; B)_\rho := \min_{\sigma_{AB} \in \text{PPT}(A; B)} D_H^\varepsilon(\rho_{AB} || \sigma_{AB}),$$

the hypothesis testing relative entropy $D_H^\varepsilon(\omega || \tau)$ is defined for a state $\omega$ and a positive semi-definite operator $\tau$ as [33]–[35]

$$D_H^\varepsilon(\omega || \tau) := -\log_2 \left\{\min_{\Lambda \geq 0} \text{Tr}[\Lambda |\tau| : \text{Tr}[\Lambda |\omega|] \geq 1 - \varepsilon, \Lambda \leq I\right\},$$

and the set $\text{PPT}'(A; B)$ as [36]

$$\text{PPT}'(A; B) := \{\sigma_{AB} : \sigma_{AB} \geq 0, \|T_B(\sigma_{AB})\|_1 \leq 1\}.$$
Note that [9], [37]

\[ D_\varepsilon^T(\rho \| \tau) := -\log_2 \left\{ \min_{\Lambda \geq 0} \text{Tr}[\Lambda \tau] : \text{Tr}[\Lambda \omega] = 1 - \varepsilon, \Lambda \leq I \right\}. \] (12)

In the above, \( T_B \) denotes the partial transpose. The inequality in (8) follows as a consequence of Theorem 4 of [20]. Alternatively, see Theorem 8.7 of [9].

The next step involves the following identity for the \( \varepsilon \)-Rains relative entropy of a maximally entangled state \( \Phi_{AB}^m \).

\[ R_\varepsilon^T(A; B)_{\Phi^d} = \log_2 d + \log_2 \left( \frac{1}{1 - \varepsilon} \right). \] (13)

This identity is established in Proposition 1 and is the main technical contribution of this paper.

Finally, we consider the following sequence of transformations:

\[ \Phi_{\varepsilon_{\varepsilon_1} B'}^{d''} \leq_{\rho_{\varepsilon_2} AB} \text{,} \Phi_{\varepsilon_2 A'B''}^{d''}, \] (14)

where the arrows indicate that the transformations take place by means of LOCC channels \( \mathcal{L}_{1}^{1} A'B' \rightarrow AB \) and \( \mathcal{L}_{2}^{2} A'B' \rightarrow A''B'' \), with an approximation error of \( \varepsilon_1 \) and \( \varepsilon_2 \), respectively. By making use of the definition of and the triangle inequality for the sine distance and its data-processing inequality, the total error of the transformation from \( \Phi_{\varepsilon_{\varepsilon_1} B'}^{d''} \) to \( \Phi_{\varepsilon_2 A'B''}^{d''} \) is no larger than \( \varepsilon' \) because the following inequalities hold by assumption

\[ F(\mathcal{L}_{1}^{1} A'B' \rightarrow AB(\Phi_{\varepsilon_{\varepsilon_1} B'}^{d''}, \rho_{AB}) \geq -\varepsilon_1, \] (15)

\[ F(\mathcal{L}_{2}^{2} A'B' \rightarrow A''B''(\rho_{AB}, \Phi_{\varepsilon_2 A'B''}^{d''}) \geq -\varepsilon_2, \] (16)

so that

\[ P(\mathcal{L}_{2}^{2} A'B' \rightarrow A''B'' \circ \mathcal{L}_{1}^{1} A'B' \rightarrow AB)(\Phi_{\varepsilon_{\varepsilon_1} B'}^{d''}, \Phi_{\varepsilon_2 A'B''}^{d''}) \leq \sqrt{\varepsilon_1} + \sqrt{\varepsilon_2}. \] (17)

The transformation in (14) can be understood as a particular way to perform entanglement distillation of the state \( \Phi_{\varepsilon_{\varepsilon_1} B'}^{d''} \) to the state \( \Phi_{\varepsilon_2 A'B''}^{d''} \) with error \( \varepsilon' \). As such, we find that

\[ \log_2 d_{\text{out}} \leq \log_2 d_{\text{in}} + \log_2 \left( \frac{1}{1 - \varepsilon'} \right), \] (18)

because

\[ \log_2 d_{\text{out}} \leq E_D'(A'; B')_{\Phi^d_{\varepsilon_{\varepsilon_1}}} \] (19)

\[ \leq R_\varepsilon^T(A'; B')_{\Phi^d_{\varepsilon_{\varepsilon_1}}} \] (20)

\[ = \log_2 d_{\text{in}} + \log_2 \left( \frac{1}{1 - \varepsilon'} \right). \] (21)

The first inequality is a consequence of the definition of one-shot distillable entanglement in (5). The second inequality follows from (8), and the equality follows from (13). Since the inequality in (13) holds for every entanglement dilution protocol \( \mathcal{L}_{1}^{1} A'B' \rightarrow AB \) taking \( \Phi_{\varepsilon_{\varepsilon_1} B'}^{d''} \) to \( \rho_{AB} \) with error \( \varepsilon_1 \) and for every entanglement distillation protocol \( \mathcal{L}_{2}^{2} A'B' \rightarrow A''B'' \) taking \( \rho_{AB} \) to \( \Phi_{\varepsilon_2 A'B''}^{d''} \) with error \( \varepsilon_2 \), we can take an infimum over \( d_{\text{in}} \) and a supremum over \( d_{\text{out}} \), apply the definitions in (6) and (5), respectively, and conclude the inequality in (7).

Let us now prove (13):

Proposition 1: For \( \varepsilon \in [0, 1) \), the \( \varepsilon \)-Rains relative entropy of the maximally entangled state \( \Phi_{AB}^d \) is as follows:

\[ R_\varepsilon^T(A; B)_{\Phi^d} = \log_2 d + \log_2 \left( \frac{1}{1 - \varepsilon} \right). \] (22)

Proof: The maximally entangled state \( \Phi_{AB}^d \) is invariant under a bilateral twist:

\[ \Phi_{AB}^d = \mathcal{T}_{AB}(\Phi_{AB}^d), \] (23)

where

\[ \mathcal{T}_{AB}(X_{AB}) := \int dU \left( U_A \otimes \overline{U}_B \right) X_{AB} \left( U_A \otimes \overline{U}_B \right)^\dagger. \] (24)

Recall that (13)

\[ \mathcal{T}_{AB}(X_{AB}) = \Phi_{AB}^d \text{Tr}[\Phi_{AB}^d X_{AB}] + \frac{I_{AB} - \Phi_{AB}^d}{d^2 - 1} \text{Tr}[(I_{AB} - \Phi_{AB}^d)X_{AB}]. \] (25)

The twisting channel \( \mathcal{T}_{AB} \) is an LOCC channel. As such, for every operator \( \sigma_{AB} \in \text{PPT}'(A : B) \), it follows that \( \mathcal{T}_{AB}(\sigma_{AB}) \in \text{PPT}'(A : B) \) [18], [38], [39], and we find that

\[ D_\varepsilon^T(\Phi_{AB}^d || \sigma_{AB}) \geq D_\varepsilon^T(\mathcal{T}_{AB}(\Phi_{AB}^d) || \sigma_{AB}), \] (26)

\[ = D_\varepsilon^T(\Phi_{AB}^d || \mathcal{T}_{AB}(\sigma_{AB})), \] (27)

where we used the data-processing inequality for the hypothesis testing relative entropy. Thus, it suffices to minimize \( R_\varepsilon^T(A; B)_{\Phi^d} \) with respect to \( \mathcal{T}_{AB}(\sigma_{AB}) \). By applying (25), it follows that all such states have the following form:

\[ \mathcal{T}_{AB}(\sigma_{AB}) = \alpha \Phi_{AB}^d + \beta \left( \frac{I_{AB} - \Phi_{AB}^d}{d^2 - 1} \right), \] (28)

where \( \alpha, \beta \in [0, 1] \) are such that \( \mathcal{T}_{AB}(\sigma_{AB}) \in \text{PPT}'(A : B) \). We now determine the conditions on \( \alpha \) and \( \beta \) such that \( \mathcal{T}_{AB}(\sigma_{AB}) \in \text{PPT}'(A : B) \). We first require \( \alpha, \beta \geq 0 \) so that \( \mathcal{T}_{AB}(\sigma_{AB}) \) is positive semi-definite. Also, consider that

\[ \left\| \alpha \mathcal{T}_{B}(\Phi_{AB}^d) + \beta \mathcal{T}_{B}\left( \frac{I_{AB} - \Phi_{AB}^d}{d^2 - 1} \right) \right\|_1 \]

\[ = \left\| \frac{\alpha}{d} F_{AB} + \beta \left( \frac{I_{AB} - \frac{1}{d} F_{AB}}{d^2 - 1} \right) \right\|_1 \] (29)

\[ = \left\| \frac{1}{d} \left( \alpha - \frac{\beta}{d^2 - 1} \right) F_{AB} + \frac{\beta}{d^2 - 1} I_{AB} \right\|_1, \] (30)

where we applied the fact that

\[ \mathcal{T}_{B}(\Phi_{AB}^d) = \frac{1}{d} F_{AB}. \] (31)

with \( F_{AB} \) the unitary swap operator:

\[ F_{AB} := \sum_{i,j=0}^{d-1} |i⟩⟨j|_{A} \otimes |j⟩⟨i|_{B}. \] (32)

Now consider defining the projections \( \Pi_{AB}^S \) and \( \Pi_{AB}^A \) onto the symmetric and antisymmetric subspaces, respectively, in terms
of $I_{AB} = \Pi^S_{AB} + \Pi^4_{AB}$ and $F_{AB} = \Pi^S_{AB} - \Pi^4_{AB}$. Plugging in to \[30\], we find that

$$
\frac{1}{d} \left( \alpha - \frac{\beta}{d^2 - 1} \right) (\Pi^S_{AB} - \Pi^4_{AB}) + \frac{\beta}{d^2 - 1} (\Pi^S_{AB} + \Pi^4_{AB})
$$

Continuing, the last line above is equal to

$$
\frac{1}{d} \left( \alpha - \frac{\beta}{d^2 - 1} \right) + \frac{\beta}{d^2 - 1} \left( \frac{d(d+1)}{2} \right) + \frac{\beta}{d^2 - 1} \left( \frac{d(d-1)}{2} \right).
$$

Thus, to have that $\mathcal{T}_{AB}(\sigma_{AB}) \in \text{PPT}'(A : B)$, we require that $\alpha, \beta \geq 0$ and $\alpha + \beta \leq 1$ if $\beta \geq \alpha (d-1)$ and $\alpha d \leq 1$ if $\beta < \alpha (d-1)$. Let PPT' be a shorthand for the set of $\alpha$ and $\beta$ satisfying these conditions. Note that $\beta \geq \alpha (d-1)$ implies that

\[1 \geq \alpha + \beta \geq \alpha + \alpha (d-1) = \alpha d,\]

so that

$$
\alpha \leq \frac{1}{d}
$$

for all $(\alpha, \beta) \in \text{PPT}'$.

Then we find that

$$
\inf_{\sigma_{AB} \in \text{PPT}(A : B)} D^\varepsilon_H(\rho_{AB} \| \sigma_{AB})
$$

where

$$
f(\Lambda_{AB}, \alpha, \beta) := \text{Tr} \Lambda_{AB} \left( \alpha \Phi_{AB} + \beta \left( \frac{I_{AB} - \Phi_{AB}}{d^2 - 1} \right) \right).
$$

Since $\Phi_{AB}$ and $\alpha \Phi_{AB} + \beta \left( \frac{I_{AB} - \Phi_{AB}}{d^2 - 1} \right)$ are both isotropic in form, it suffices to optimize over measurement operators $\Lambda_{AB}$ that satisfy the same symmetry, giving that

$$
\mathcal{T}_{AB}(\Lambda_{AB}) = \kappa \Phi_{AB} + \lambda \left( \frac{I_{AB} - \Phi_{AB}}{d^2 - 1} \right),
$$

where we again apply \[25\]. The conditions on $\kappa$ and $\lambda$ such that $\mathcal{T}_{AB}(\Lambda_{AB})$ is a measurement operator are that $\kappa, \lambda \geq 0$ and $\kappa, \frac{\lambda}{d^2 - 1} \leq 1$. Then we find that

$$
\text{Tr}[\Lambda_{AB} \Phi_{AB}] = \text{Tr}[\mathcal{T}_{AB}(\Lambda_{AB}) \Phi_{AB}] = \kappa,
$$

so that $\kappa = 1 - \varepsilon$. Plugging into \[43\], we find that

$$
\text{Tr} \left[ \Lambda_{AB} \left( \alpha \Phi_{AB} + \beta \left( \frac{I_{AB} - \Phi_{AB}}{d^2 - 1} \right) \right) \right] = \text{Tr} \left[ \mathcal{T}_{AB}(\Lambda_{AB}) \left( \alpha \Phi_{AB} + \beta \left( \frac{I_{AB} - \Phi_{AB}}{d^2 - 1} \right) \right) \right]
$$

Thus, we find that

$$
\inf_{\sigma_{AB} \in \text{PPT}'(A : B)} D^\varepsilon_H(\rho_{AB} \| \sigma_{AB})
$$

$$
= -\log_2 \inf_{(\alpha, \beta) \in \text{PPT}'} \left\{ (1 - \varepsilon) \alpha + \frac{\lambda^2}{d^2 - 1} : 0 \leq \alpha, \beta \leq \frac{d^2 - 1}{\lambda^2} \right\}
$$

$$
= -\log_2 \sup_{(\alpha, \beta) \in \text{PPT}'} (1 - \varepsilon) \alpha
$$

$$
= -\log_2 (1 - \varepsilon) \frac{1}{d} = \log_2 d + \log_2 \left( \frac{1}{1 - \varepsilon} \right).
$$

This concludes the proof.

IV. SECOND LAW OF ENTANGLEMENT DYNAMICS IN THE ASYMPTOTIC REGIME

As a consequence of Theorem 1, it follows that the distillable entanglement does not exceed the entanglement cost (which we recalled in the introduction is often argued based on physical grounds). To see this, let us first define the distillable entanglement and entanglement cost of a bipartite state $\rho_{AB}$.

The distillable entanglement is defined as

$$
E_D(A; B)_\rho := \inf_{\varepsilon \in (0, 1)} \lim_{n \to \infty} \frac{1}{n} E_D(A^n; B^n)_{\rho^n},
$$

and the entanglement cost as

$$
E_C(A; B)_\rho := \sup_{\varepsilon \in (0, 1)} \lim_{n \to \infty} \frac{1}{n} E_C(A^n; B^n)_{\rho^n}.
$$

In words, the distillable entanglement $E_D(A; B)_\rho$ is equal to the largest rate at which ebits can be extracted approximately
from $\rho_{AB}^n$ by means of LOCC, such that the error converges to zero in the limit $n \to \infty$, and the entanglement cost $E_C(A; B)_\rho$ is the smallest rate at which ebits are needed to generate $\rho_{AB}^n$ approximately by means of LOCC, such that the error converges to zero in the limit $n \to \infty$. The values of $E_D(A; B)_\rho$ and $E_C(A; B)_\rho$ in (52) and (53), respectively, are unchanged by optimizing over $\varepsilon \in (0, c)$ for $c \in (0, 1)$, due to the monotonicity fact stated after (6).

**Corollary 1**: For every bipartite state $\rho_{AB}$, the following inequality holds

$$E_D(A; B)_\rho \leq E_C(A; B)_\rho. \quad (54)$$

**Proof**: Using the inequality from Theorem 1 we find for $\varepsilon \in (0, 1/2)$ that

$$\liminf_{n \to \infty} \frac{1}{n} E_D^n(A^n; B^n)_{\rho^n} \leq \limsup_{n \to \infty} \frac{1}{n} E_D^n(A^n; B^n)_{\rho^n} \leq \limsup_{n \to \infty} \frac{1}{n} \left[ E_C^n(A^n; B^n)_{\rho^n} + \log_2 \left( \frac{1}{1 - 4\varepsilon (1 - \varepsilon)} \right) \right] = \limsup_{n \to \infty} \frac{1}{n} E_C^n(A^n; B^n)_{\rho^n}. \quad (55)$$

Taking the infimum over $\varepsilon \in (0, 1/2)$ on the left and the supremum over $\varepsilon \in (0, 1/2)$ on the right, we conclude the inequality in (54).

The strong converse distillable entanglement and strong converse entanglement cost are defined respectively as follows:

$$\tilde{E}_D(A; B)_\rho := \sup_{\varepsilon \in (0, 1)} \limsup_{n \to \infty} \frac{1}{n} E_D^n(A^n; B^n)_{\rho^n}, \quad (56)$$

$$\tilde{E}_C(A; B)_\rho := \inf_{\varepsilon \in (0, 1)} \liminf_{n \to \infty} \frac{1}{n} E_C^n(A^n; B^n)_{\rho^n}. \quad (57)$$

The inequalities $E_D(A; B)_\rho \leq \tilde{E}_D(A; B)_\rho$ and $\tilde{E}_C(A; B)_\rho \leq E_C(A; B)_\rho$ are an immediate consequence of definitions. However, it is not clear how to use the inequality from Theorem 1 to arrive at a similar statement for the strong converse quantities. That is, the following remains an open question:

$$\tilde{E}_D(A; B)_\rho \leq \tilde{E}_C(A; B)_\rho. \quad (58)$$

**V. RESULTS FOR NORMALIZED TRACE DISTANCE ERROR**

We can extend the results here to the case when errors are measured by normalized trace distance, rather than fidelity. Let us define one-shot distillable entanglement and one-shot entanglement cost using this modified notion of error:

$$E_{D, T}^n(A; B)_\rho := \sup_{d \in \mathcal{L}, L \in \text{LOCC}} \left\{ \log_2 d : \frac{1}{2} ||L_{AB} \rightarrow \tilde{A} \tilde{B} (\rho_{AB}) - \Phi_{AB}^d||_1 \leq \varepsilon \right\}, \quad (59)$$

$$E_{C, T}^n(A; B)_\rho := \inf_{d \in \mathcal{L}, L \in \text{LOCC}} \left\{ \log_2 d : \frac{1}{2} ||L_{AB} \rightarrow \tilde{A} \tilde{B} (\Phi_{AB}^d) - \rho_{AB}||_1 \leq \varepsilon \right\}. \quad (60)$$

**Theorem 2**: Let $\rho_{AB}$ be a bipartite state, and let $\varepsilon_1, \varepsilon_2 \in [0, 1]$ be such that $\varepsilon_1 + \varepsilon_2 < 1$. Then

$$E_{D, T}^n(A; B)_\rho \leq E_{C, T}^n(A; B)_\rho + \log_2 \left( \frac{1}{1 - \varepsilon_1 - \varepsilon_2} \right). \quad (61)$$

**Proof**: The proof idea is essentially the same as that for Theorem 1, but we substitute the first part of its proof with the following bound:

$$E_{D, T}^n(A; B)_\rho \leq R_H(A; B)_\rho \quad \forall \varepsilon \in [0, 1], \quad (62)$$

and the last part with the triangle inequality for the normalized trace distance. The inequality in (62) follows from the fact that

$$\frac{1}{2} ||\Phi_{AB} - \omega_{AB}||_1 \leq \varepsilon \Rightarrow \text{Tr}[\Phi_{AB} \omega_{AB}] \geq 1 - \varepsilon, \quad (63)$$

along with Proposition 8.6 and Theorem 8.7 of [9]. To see (63), consider that applying the measurement channel $(\cdot) \rightarrow \text{Tr}[\Phi_{AB}(\cdot)] |1\rangle \langle 1 | + \text{Tr}[(I_{AB} - \Phi_{AB})(\cdot)] |0\rangle \langle 0 |$ and the data-processing inequality for trace distance implies that

$$\varepsilon \geq \frac{1}{2} ||\Phi_{AB} - \omega_{AB}||_1 \quad (64)$$

$$= \frac{1}{2} \left| \left| |1\rangle \langle 1 | - \text{Tr}[\Phi_{AB} \omega_{AB}] |1\rangle \langle 1 | \right| \right|_1 \quad (65)$$

$$= \frac{1}{2} \left| \left| (1 - \text{Tr}[\Phi_{AB} \omega_{AB}]) (|1\rangle \langle 1 | - |0\rangle \langle 0 |) \right| \right|_1 \quad (66)$$

$$= 1 - \text{Tr}[\Phi_{AB} \omega_{AB}]. \quad (67)$$

This concludes the proof.

**VI. DISCUSSION**

The result of Theorem 1 applies far more generally to the resource theory of entanglement for bipartite channels [21–25]. This follows because the proof of Theorem 1 relies on the sequence of transformations in (13). By substituting the state $\rho_{AB}$ there with a bipartite channel, or $n$ sequential uses of it, we conclude that the same bound holds with $E_{D, T}^n(A; B)_\rho$ replaced by the one-shot distillable entanglement of a bipartite channel and $E_{C, T}^n(A; B)_\rho$ replaced by the one-shot entanglement cost of the same bipartite channel. Alternatively, these could be replaced by the $n$-shot distillable entanglement and $n$-shot entanglement cost, respectively, defined in the sequential way outlined in [24, 25].

More generally, one can extend the reasoning here to arbitrary quantum resource theories [40] (in fact the method used here is the same conceptually as that used to arrive at Eq. (51) of [41] and Eq. (50) of [42]). The main ingredients needed are a golden-unit resource like the maximally entangled state, a bound on one-shot distillable resource like the $\varepsilon$-Rains relative entropy, and an exact evaluation of the golden-unit resource for this bound.
