Abstract
We settle the parameterized complexities of several variants of independent set reconfiguration and dominating set reconfiguration, parameterized by the number of tokens. We show that both problems are XL-complete when there is no limit on the number of moves and XNL-complete when a maximum length $\ell$ for the sequence is given in binary in the input. The problems are known to be XNLP-complete when $\ell$ is given in unary instead, and $W[1]$- and $W[2]$-hard respectively when $\ell$ is also a parameter. We complete the picture by showing membership in those classes.

Moreover, we show that for all the variants that we consider, token sliding and token jumping are equivalent under pl-reductions. We introduce partitioned variants of token jumping and token sliding, and give pl-reductions between the four variants that have precise control over the number of tokens and the length of the reconfiguration sequence.

1 Introduction

In this paper, we study the parameterized complexity of reconfiguration of independent sets, and of dominating sets, with the sizes of the sets as parameter. Interestingly, the complexity varies depending on the assumptions on the length of the reconfiguration sequence, which can be unbounded, given in binary, given in unary, or given as second parameter. One can study the reconfiguration problems for different reconfiguration rules; we will show equivalence regarding the complexity for several reconfiguration rules.

Independent Set Reconfiguration

In the Independent Set Reconfiguration problem, we are given a graph and two independent sets $A$ and $B$, and wish to decide we can ‘reconfigure’ $A$ to $B$ via a ‘valid’ sequence of independent sets $A, I_1, \ldots, I_{\ell-1}, B$. Suppose that we represent the current independent set by placing a token on each vertex. We can move between two independent sets by moving a single token. We consider two well-studied rules for deciding how we can move the tokens.

- Token jumping (TJ): we can ‘jump’ a single token to any vertex that does not yet contain a token.
- Token sliding (TS): we can ‘slide’ a single token to an adjacent vertex that does not yet contain a token.

Independent Set Reconfiguration is PSPACE-complete for both rules [8], but their complexities may be different when restricting to specific graph classes. For example, Independent Set Reconfiguration is NP-complete on bipartite graphs under the token jumping rule, but remains PSPACE-complete under the token sliding rule [10]. There is a third rule which has been widely studied, called the token addition-removal rule, but this rule is equivalent to the token jumping rule for our purposes (see e.g. [8, Theorem 1]). As further explained later, we show that the token jumping and the token sliding rule are also equivalent in some sense (which is much weaker but does allow us to control all the parameters that we care about). We will therefore not explicitly mention the specific rule under consideration below.

Throughout this paper, our reconfiguration problems are parameterized by the number of tokens (the size of the independent set). Independent Set Reconfiguration is $W[1]$-hard [6], but the problem is not known to be in $W[1]$. We show that in fact it is complete for the class $XL$, consisting of the parameterized problems that can be solved by a deterministic algorithm that uses $f(k) \log n$ space, where $k$ is the parameter, $n$ the input size and $f$ any computable function.

\begin{theorem}
Independent Set Reconfiguration is $XL$-complete.
\end{theorem}

In the Timed Independent Set Reconfiguration, we are given an integer $\ell$ in unary and two independent sets $A$ and $B$ in a graph $G$, and need to decide whether there is a reconfiguration sequence from $A$ to $B$ of length at most $\ell$. We again parameterize it by the number of tokens. The following result has been shown by the authors and Nederlof [11].

\begin{theorem}[11]
Timed Independent Set Reconfiguration is $XNLP$-complete.
\end{theorem}

The class XNLP (also denoted $N[f\text{poly}, f\log]$ by Elberfeld et al. [4]) is the class of parameterized problems that can be solved with a non-deterministic algorithm with simultaneously, the running time bounded by $f(k)n^c$ and the space usage bounded by $f(k)\log n$, with $k$ the parameter, $n$ the input size, $c$ a constant, and $f$ a computable function. This is a natural
Sequence length $\ell$ | Independent Set | Dominating Set | Sources
--- | --- | --- | ---
not given | XL-complete | XL-complete | Theorems 3, 5
parameter | $W[1]$-complete | $W[2]$-complete | Theorems 4, 5 and 11
unary input | XNLP-complete | XNLP-complete | 11
binary input | XNL-complete | XNL-complete | Theorems 3, 5

Table 1 The table shows the parameterized complexities of the independent set and dominating set reconfiguration problems, parameterized by the number of tokens, depending on the treatment of the bound $\ell$ on the length of the reconfiguration sequence.

subclass of the class XNL, which consists of the parameterized problems that can be solved by a nondeterministic algorithm that uses $f(k)\log n$ space. Amongst others, XNL was studied by Chen et al. [2].

The classes XL, XNL, XSL, XP can be seen as the parameterized counterparts of L, NL, SL, P respectively. Although no explicit time bound is given, we can freely add a time bound of $2^{f(k)\log n}$, and thus XNL is a subset of XP. We remark that $XL=XS[1][15]$ (just as $L=SL$), $XL \subseteq XNL$ and $XNLP \subseteq XNL$.

In Binary Timed Independent Set Reconfiguration, the bound $\ell$ on the length of the sequence is given in binary. Interestingly, this slight adjustment to Timed Independent Set Reconfiguration is complete for XNL instead.

▶ Theorem 3. Binary Timed Independent Set Reconfiguration is XNL-complete.

Finally, we consider what happens when we consider $\ell$ to be a parameter instead. If Timed Independent Set Reconfiguration (or equivalently Binary Timed Independent Set Reconfiguration) is parameterized by the size of the independent set and the length of the sequence, then it is $W[1]$-hard [11]. We show that in this case, $W[1]$ is the ‘correct class’.

▶ Theorem 4. Timed Independent Set Reconfiguration is in $W[1]$ when parameterized by the size of the independent set and the length of the sequence.

Dominating set reconfiguration

The dominating set reconfiguration problem is similar to the independent set reconfiguration problem, but in this case all sets in the sequence must form a dominating set in the graph. This again gives a PSPACE-complete problem [5]. We define the parameterized problems Dominating Set Reconfiguration, Timed Dominating Set Reconfiguration and Binary Timed Dominating Set Reconfiguration similarly as their independent set counterparts, again parameterized by the number of tokens. Since Dominating Set is $W[2]$-complete and Independent Set is $W[1]$-complete (parameterized by ‘the number of tokens’), it may be expected that the reconfiguration variants also do not have the

---

1 A proof can be found in Appendix A
2 Giving $\ell$ in binary implies that it contributes $\log_2(\ell)$ to the size of an instance of Binary Timed Independent Set Reconfiguration.
3 We can also consider it to be parameterized by the sum of the two parameters.
4 Mouawad et al. [11] only studied the token jumping variant, but Theorem [6] implies the hardness also holds for token sliding.
same parameterized complexity. Indeed, Timed Dominating Set Reconfiguration is \( W[2] \)-hard when it is moreover parameterized by the length of the sequence \([1]\).

We show that the picture is otherwise the same as for independent set.

\[ \textbf{Theorem 5.} \] Dominating Set Reconfiguration is \( XL \)-complete. Binary Timed Dominating Set Reconfiguration is \( XNL \)-complete. Timed Dominating Set Reconfiguration is \( W[2] \)-complete when moreover parameterized by the length of the sequence.

It was already known that Timed Dominating Set Reconfiguration is \( XNLP \)-complete \([1]\). We give the proof of Theorem 5 in Appendix C. A summary of our results can be found in Table 1.

Many other types of reconfiguration problems have been studied as well, and we refer the reader to the surveys by Van den Heuvel \([14]\) and Nishimura \([12]\) for further background.

\[ \textbf{Equivalences between token jumping and token sliding} \]

In Appendix \([13]\) we introduce partitioned variants of token sliding and token jumping in which the tokens need to stay within specified token sets. We prove the theorem below by giving reductions from and to the independent set reconfiguration problems (with the four rules: (partitioned) token sliding and (partitioned) token jumping) that control the number of tokens and the length of the reconfiguration sequence. We give similar reductions for the dominating set reconfiguration problems.

\[ \textbf{Theorem 6.} \] For the following parameterized problems, their variant with the token jumping rule is equivalent under pl-reductions and fpt-reductions to their variant with the token sliding rule: Independent Set Reconfiguration, Timed Independent Set Reconfiguration, Binary Independent Set Reconfiguration and Timed Independent Set Reconfiguration when moreover parameterized by the length of the sequence. The same holds for the dominating set variants.

\section{Preliminaries}

We write \( \mathbb{N} \) for the set of integers \( 0, 1, 2, \ldots \) and write \([a, b]\) for the set of integers \( x \) with \( a \leq x \leq b \). All logs in this paper are base 2.

\[ \textbf{Parameterized reductions} \]

A \textit{parameterized reduction} from a parameterized problem \( Q_1 \subseteq \Sigma_1^* \times \mathbb{N} \) to a parameterized problem \( Q_2 \subseteq \Sigma_2^* \times \mathbb{N} \) is a function \( f : \Sigma_1^* \times \mathbb{N} \rightarrow \Sigma_2^* \times \mathbb{N} \), such that the following holds.

1. For all \( (x, k) \in \Sigma_1^* \times \mathbb{N} \), \( (x, k) \in Q_1 \) if and only if \( f((x, k)) \in Q_2 \).
2. There is a computable function \( g \), such that for all \( (x, k) \in \Sigma_1^* \times \mathbb{N} \), if \( f((x, k)) = (y, k') \), then \( k' \leq g(k) \).

A \textit{parameterized logspace reduction} or \textit{pl-reduction} is a parameterized reduction for which there is an algorithm that computes \( f((x, k)) \) in space \( O(g(k) + \log n) \), with \( g \) a computable function and \( n = |x| \) the number of bits to denote \( x \).

\[ \textbf{Symmetric Turing Machine} \]

A Symmetric Turing Machine (STM) is a Nondeterministic Turing Machine (NTM), where the transitions are symmetric. That means that for any transition, we can also take its inverse back. More formally, a Symmetric Turing Machine with one work tape is a 5-tuple...
(S, Σ, T, s_start, A), where S is a finite set of states, Σ is the alphabet, T is the set of transitions, s_start is the start state and A is the set of accepting states. A transition τ ∈ T is a tuple of the form (p, Δ, q) describing a transition the STM may take, where p, q ∈ S are states and Δ is a tape triple. A tape triple is equal to either (ab, δ, cd), where a, b, c, d ∈ Σ and δ ∈ {−1, 1}, or (a, 0, b), where a, b ∈ Σ. For example, the transition (p, (ab, 1, cd), q) describes that if the STM is in state p, reads a and b on the current work tape cell and the cell directly right of it, then it can replace a with c, b with d, moving the head to the right and going to state q.

Let Δ = (ab, δ, cd) be a state triple, then its inverse is defined as Δ−1 = (cd, −δ, ab). The inverse of Δ = (a, 0, b) is defined as Δ−1 = (b, 0, a). By definition of the Symmetric Turing Machine, for any τ ∈ T, there is an inverse transition τ−1 ∈ T, i.e. if τ = (p, Δ, q) ∈ T, then τ−1 = (q, Δ−1, p) ∈ T.

We say that STM M accepts if there is a computation of M that ends in an accepting state. We remark that the Turing Machines in this paper do not have an input tape, as it is hidden in the states (see Appendix A). For a more formal definition of Symmetric Turing Machines we would like to refer to the definition from Louis and Papadimitriou in [9].

Note that we may assume that there is only one accepting state s_acc ∈ A, by creating this new state s_acc and adding a transition to s_acc from any original accepting state. We may also assume all transitions to move the tape head to the left or right. This can be accomplished by replacing each transition τ = (p, (a, 0, b), q) with 2|Σ| transitions as follows. For all σ ∈ Σ, we create a new state s_σ and two new transitions τ_σ^1 = (p, (aσ, 1, bσ), s_σ) and τ_σ^2 = (s_σ, (bσ, −1, bσ), q).

The following problem will be used in the reductions of Section 3.

**Accepting Log-Space Symmetric Turing Machine**

**Given:** A STM M = (S, Σ, T, s_start, A) with Σ = [1, n] and a work tape with k cells.

**Parameter:** k.

**Question:** Does M accept?

We define **Accepting Log-Space Nondeterministic Turing Machine** to be the Nondeterministic Turing Machine analogue of Accepting Log-Space Symmetric Turing Machine.

**Theorem 7.** Accepting Log-Space Symmetric Turing Machine is XL-complete and Accepting Log-Space Nondeterministic Turing Machine is XNL-complete.

We include a proof of Theorem 7 in Appendix A for completeness. In our reductions we use the notion of a configuration, describing exactly in what state an NTM (and therefore an STM) and its tape are.

**Definition 8.** Let M = (S, Σ, T, s_start, A) be an NTM with Σ = [1, n] and k cells on the work tape and let α ∈ Σ* be the input. A configuration of M is a k + 2 tuple (p, i, σ_1, ..., σ_k) where p ∈ S, i ∈ [1, k] and σ_1, ..., σ_k ∈ Σ, describing the state, head position and content of the work tape of M respectively.

### 3 Proof of Theorem 1: XL-completeness

By Theorem 6 it suffices to show that the following problem is XL-complete.

**Partitioned TS-Independent Set Reconfiguration**

**Given:** Graph G = (V, E); independent sets I_init, I_fin of size k; a partition V = ∪_{i=1}^{k} P_i of the vertex set.
Parameter: $k$.

**Question:** Does there exist a sequence $I_{init} = I_0, I_1, \ldots, I_T = I_{fin}$ of independent sets of size $k$ for some $T$, with $|I_t \cap P_i| = 1$ for all $t \in [0, T]$ and $i \in [1, k]$, such that for all $t \in [1, T]$, $I_t = I_{t-1} \setminus \{u\} \cup \{v\}$ for some $uv \in E(G)$ with $u \in I_{t-1}$ and $v \notin I_{t-1}$?

Theorem 6 then implies the XL-completeness results for the other variants of **INDEPENDENT SET RECONFIGURATION**.

The XL-completeness proof for **PARTITIONED TS-DOMINATING SET RECONFIGURATION** is similar and given in Appendix C.

**Theorem 9.** **PARTITIONED TS-INDEPENDENT SET RECONFIGURATION** is XL-complete.

**Proof.** By Theorem 7, it suffices to give pl-reductions to and from **ACCEPTING LOG-SPACE SYMMETRIC TURING MACHINE**.

The problem is in XL (=XSL) as it can be simulated with a Symmetric Turing Machine with $O(k \log n)$ space as follows. We store the current independent set of size $k$ on the work tape, which takes about $k \cdot \log n$ bits space. We use the transitions of the STM to model the changes of one of the vertices in the independent set. For all vertices $u, v \in V$, we have a sequence of states and transitions that allows you to remove $u$ and add $v$ to the independent set currently stored on the work tape, if the following assumptions are met: $u \in I$, $v \notin I$, $uv \in E(G)$, $u, v$ are part of the same token set (part of the partition) and $I'$ is an independent set. This gives a total of $O(n^2 k^2)$ states. There is one accepting state, reachable via a sequence of states and transitions that verifies that the current independent set is the final independent set. All transitions are symmetric.

We prove the problem to be XL-hard by giving a reduction from **ACCEPTING LOG-SPACE SYMMETRIC TURING MACHINE**. Let $M = (S, \Sigma, T, s_{\text{start}}, A)$ be the STM of a given instance, with $A = \{s_{\text{acc}}\}$, $\Sigma = [1, n]$ and a work tape of $k$ cells. We may assume that $M$ only accepts if the symbol 1 is on every cell of the work tape and the head is at the first position. This can be done by creating a new accepting state and adding $O(k)$ transitions from $s_{\text{acc}}$ to this new state, which set only 1’s on the work tape and move the head to the first position. We create an instance $\Gamma$ of **PARTITIONED TS-INDEPENDENT SET RECONFIGURATION** with $k' = k + 1$ tokens. These tokens will simulate the configuration of $M$: $k$ tape-tokens modeling the work tape cells and one state token describing the current state and tape head position.

**Tape gadgets.** For each work tape cell $i \in [1, k]$, we create a tape gadget consisting of $n + 1$ vertices as follows. We add a vertex $v_{\sigma}^i$ for all $\sigma \in \Sigma = [1, n]$ and a vertex $y^i$, connected to $v_{\sigma}^i$ for all $\sigma \in \Sigma$. The vertices in a tape gadget form a token set (a part of the partition, i.e. exactly one of these $n + 1$ vertices is in the independent set at any given time). The symbol $\sigma$ that is on the $i$th work tape cell of $M$ is simulated by which $v_{\sigma}^i$ is in the independent set.

**State vertices.** The last token set is the set of all transition and state vertices (defined below), meaning that exactly one of these vertices is in the independent set at any given time. The token of this set (called the ‘state token’) simulates the state of $M$, the position of the head, and the transition $M$ takes.

We create a vertex $p^i$ for each state $p \in S$ and all head positions $i \in [1, k]$. We add edges $p^iy^i$ for all $i' \in [1, k]$. These vertices will simulate the current state of $M$ and the position $i$ of the tape head.
**Transition vertices.** To go from one state vertex to another, we create a path of three transition vertices, to check whether the work tape agrees with the transition before and afterwards, and one allowing moving some tokens of the tape gadget. To control when we can move tokens in the tape gadgets, we put edges between \(y_i\) and all state and transition vertices (for each \(i \in [1,k]\)), unless specified otherwise. We further outline which edges are present below, and give an example in Figure 1.

Recall that we may assume that head always moves left or right. Consider first a transition \(\tau \in T\) that moves the head to the right, say \(\tau = (p, (ab, 1), cd), q)\). For all \(i \in [1,k-1]\), we create a path between state vertices \(p_i\) and \(q_i+1\) consisting of three ‘transition’ vertices: \(\tau_{ab}^i\), \(\tau_{\text{shift}}^i\) and \(\tau_{cd}^i\). In order to ensure a token can only be on \(\tau_{ab}^i\) when the token on the \(i\)th tape gadget represents the symbol \(a\), we add edges from \(\tau_{ab}^i\) to \(v_{i+1}^a\) for all \(\sigma \in \Sigma \setminus \{a\}\). Similarly, edges to \(v_{i+1}^b\) are added for all \(\sigma \in \Sigma \setminus \{b\}\), as well as edges between \(\tau_{cd}^i\) and all \(v_{i+1}^a\) except for \(v_{i+1}^c\) and \(v_{i+1}^d\). When the token is on the shift vertex \(\tau_{\text{shift}}^i\), the independent set is allowed to change the token in the \(i\)th and \((i+1)\)th tape gadget. Therefore, we remove the edges between \(y_i\) and \(y_i+1\) and \(\tau_{\text{shift}}^i\).

Note that the constructed paths also handle transitions which move the tape head to the left, as we can transverse the constructed paths in both directions. We omit the details.

**Initial and final independent sets.** Recall that \(s_{\text{start}}\) is the starting state of \(M\). We let the initial independent set be \(I_{\text{init}} = \{s_{\text{start}}^1\} \cup \left( \bigcup_{i \in [1,k]} \{v_i^a\} \right)\), corresponding to the initial configuration of \(M\). Let the final independent set be \(I_{\text{fin}} = \{s_{\text{acc}}^1\} \cup \left( \bigcup_{i \in [1,k]} \{v_i^a\} \right)\), where \(s_{\text{acc}}\) is the accepting state of \(M\). We note that both \(I_{\text{init}}\) and \(I_{\text{fin}}\) are independent sets.

Let \(\Gamma\) be the created instance of Partitioned TS-INDEPENDENT SET RECONFIGURATION. We prove that \(\Gamma\) is a yes-instance if and only if \(M\) accepts. We use the following function, hinting at the equivalence between configurations of \(M\) and certain independent sets of \(\Gamma\).

▶ **Definition 10.** Let \(C = (p, i, \sigma_1, \ldots, \sigma_k)\) be a configuration of \(M\). Then let \(I(C)\) be the
corresponding independent set in $\Gamma$:

$$I(C) = \{p^i\} \cup \left( \bigcup_{j=1}^{k} \{v_{\sigma_j}^{j}\} \right)$$

\[\triangleright\] Claim 11. $\Gamma$ is a yes-instance if $M$ accepts.

**Proof.** Let $C_1, \ldots, C_\ell$ be the sequence of configurations such that $M$ accepts. We note that $I(C_1) = I_{\text{init}}$. For each $t \in [1, \ell - 1]$, we do the following. Let $C_t = (p, i, \sigma_1, \ldots, \sigma_k)$. Let $\tau$ be the transition $M$ takes to the next configuration. Assume $\tau = (p, (ab, 1, cd), q)$, the case where $\tau$ moves the head to the left will be discussed later, but is similar. Take the following sequence of configurations, where $I(C_t) = I_0$ is the current independent set:

\begin{align*}
I_1 &= I_0 \setminus \{p^i\} \cup \{\tau_{ab}^i\} & I_5 &= I_4 \setminus \{v_{\sigma_6}^{i+1}\} \cup \{y^{i+1}\} \\
I_2 &= I_1 \setminus \{\tau_{ab}^i\} \cup \{\tau_{\text{shift}}^i\} & I_6 &= I_5 \setminus \{y^{i+1}\} \cup \{v_{\sigma_6}^{i+1}\} \\
I_3 &= I_2 \setminus \{v_{\sigma_6}^{i}\} \cup \{y^{i}\} & I_7 &= I_6 \setminus \{\tau_{\text{shift}}^i\} \cup \{\tau_{cd}^i\} \\
I_4 &= I_3 \setminus \{y^{i}\} \cup \{v_{\sigma_6}^{i}\} & I_8 &= I_7 \setminus \{\tau_{cd}^i\} \cup \{q^{i+1}\}
\end{align*}

Notice that this sequence of independent sets is allowed, as all sets are independent, each token stays within its token set and each next independent set is a slide away from its previous. Also, we see that $I(C_{t+1}) = I_9$. For transition $\tau = (p, (ab, -1, cd), q)$, where the tape head moves to the left, we do the following. Let $\tau^{-1} = (q, (cd, 1, ab), p)$ be the inverse. We take the sequence that belongs to $\tau^{-1}$ backwards, i.e., if $I_0, \ldots, I_9$ was the sequence of independent sets as described for $\tau^{-1}$, then take the sequence $I_8, \ldots, I_0$.

We note that $I(C_\ell) = I_{\text{fin}}$ is the final independent set, as we assumed the machine only to accept with $\sigma_i = 1$ for all $i \in [1, k]$ and the head at the first position. Therefore, we find that this created sequence of independent sets is a solution to $\Gamma$.

\[\triangleright\] We now prove the other direction.

\[\triangleright\] Claim 12. $M$ accepts if $\Gamma$ is a yes-instance.

**Proof.** Let $I_{\text{init}} = I_1, \ldots, I_{\ell-1}, I_\ell = I_{\text{fin}}$ be the sequence of independent sets that is a solution to $\Gamma$. We assume this sequence to be minimal, implying that no independent set can occur twice.

The state token should always be on either a state or transition vertex, because of its token set. Let $I_1', \ldots, I_{\ell'}'$ be the subsequence of $I_1, \ldots, I_\ell$ of independent sets that include a state vertex. We will prove that the configurations of $M$, simulated by this subsequence, is a sequence of configurations that leads to the accepting state $s_{\text{acc}}$. To do this, first we note some general facts about $I_t$ for $t \in [1, \ell]$.

If the state token of $I_t$ is on a state vertex $p^i$, then $I_{t+1}$ slides the state token to a neighbor of $p^i$. This is because all $y^i$ for $i' \in [1, k]$ are neighbors of $p^i$, hence the tokens in the tape gadgets are on some $v_{\sigma_6}^{i'}$ and cannot move. The same holds for transition vertices of the form $\tau_{ab}^i$. If $\tau_{\text{shift}}^i \in I_t$, then $y^i$ and $y^{i+1}$ are not neighbors of the state token. Therefore, the $i$th and $i + 1$th tape gadgets token can now slide. If $\tau_{ab}^i \in I_t$, then $v_{\sigma_6}^{i} \in I_t$ and $v_{\sigma_6}^{i+1} \in I_t$. This is because all other vertices of the $i$th and $i + 1$th tape gadgets are neighbors of $\tau_{ab}^i$.

Recall that $I_1', \ldots, I_{\ell'}'$ is the sequence of independent sets with the state token on a state vertex. For any $I_t'$ with $t \in [1, \ell']$, let $C_t$ be the unique configuration of $M$ such that
I(C_t) = I_t'. We prove that C_1, \ldots, C_r is an allowed sequence of configurations for \mathcal{M}. Note that this implies that \mathcal{M} accepts C_r as the accepting configuration.

We fix \ell \in [1, \ell'] and focus on the transition between C_t and C_{t+1}. Let A_1, \ldots, A_R be the sequence of independent sets in the solution of \Gamma, that are visited between I_t and I_{t+1}'. By definition of I_t' and I_{t+1}', A_r does not contain a state vertex for all r \in [1, R], therefore each A_r must have its state token on a transition vertex. Each such transition vertex corresponds to the same transition \tau = (p, \Delta, q), as this is the only path the state token can take. We assume that \Delta = (ab, 1, cd), the case \Delta = (ab, -1, cd) can be proved with similar arguments. The set A_1 contains transition vertex \tau_{ab} and therefore I_t' contains v_a^i and v_b^{i+1}. Also, A_R contains \tau_{cd}^{i-1}, implying that v_a^i, v_x^{i+1} \in I_{t+1}'. We note that A_2, \ldots, A_{R-1} must contain \tau_{ab}^{i+1}: only the ith and i + 1th tape gadget tokens can shift when the state token is on \tau_{ab}. So if the state token would be on \tau_{ab} or \tau_{cd} twice in A_1, \ldots, A_R, the independent sets would be equal, contradicting the minimal length of the sequence.

Combining this all, we conclude that if I(C_t) = I_t' and I(C_{t+1}) = I_{t+1}', there is an allowed sequence of independent set, traversing the path belonging to a transition \tau = (p, (ab, 1, cd), q). Therefore, I_{t+1} = I_t \setminus \{v_a^i, v_b^{i+1}, p\} \cup \{v_a^i, v_x^{i+1}, q, s^{i+1}\} and we are allowed to take transition \tau from C_t to end up in configuration C_{t+1}'.

Hence, \Gamma is a yes instance if and only if \mathcal{M} accepts and we find that the given reduction is correct. This concludes the proof of Theorem 3.

4 Proof of Theorem 3: XNL-completeness

In this section we prove Theorem 3 by showing that the following problem is XNL-complete.

**Binary Timed Partitioned TS-Independent Set Reconfiguration**

**Given:** Graph G = (V, E); independent sets I_m, I_f of size k; integer \ell given in binary; a partition V = \bigcup_{i=1}^{k} P_i of the vertex set.

**Parameter:** k.

**Question:** Does there exist a sequence I_m = I_0, I_1, \ldots, I_T = I_f of independent sets of size k with T \leq \ell and |I_t \cap P_i| = 1 for all t \in [0, T] and i \in [1, k], such that for all t \in [1, T], I_t = I_{t-1} \setminus \{u\} \cup \{v\} for some uv \in E(G) with u \in I_{t-1} and v \not\in I_{t-1}?

To prove XNL-hardness, we introduce a variant of CNF-SAT. The following is a ‘long chain’-variant of the XNLP-complete problems ‘chained CNF-Satisfiability’ introduced by [1].

**Long Partitioned Positive Chain Satisfiability**

**Input:** Integers k, q, r \in \mathbb{N} with r given in binary and r \leq q^k; Boolean formula F, which is an expression on 2q positive variables and in conjunctive normal form; a partition of [1, q] into k parts P_1, \ldots, P_k.

**Parameter:** k.

**Question:** Do there exist variables x_j^{(t)} for t \in [1, r] and j \in [1, q], such that we can satisfy the formula

$$\bigwedge_{1 \leq t \leq r-1} F(x_1^{(t)}, \ldots, x_q^{(t)}, x_1^{(t+1)}, \ldots, x_q^{(t+1)})$$

by setting, for i \in [1, k] and t \in [1, r], exactly one variable from the set \{x_j^{(t)} : j \in P_i\} to true and all others to false?
10 Parameterized Complexities of Dominating and Independent Set Reconfiguration

We remark that all XNLP-complete ‘chained satisfiability’ variant of [1] have an XNL-complete analogue, but we decided to only present the form we need for this section. In Appendix [B], we prove the following result.

- **Theorem 13.** Long Partitioned Positive Chain Satisfiability is XNL-complete.

From this, we derive the following result.

- **Theorem 14.** Binary Timed Partitioned TS-Independent Set Reconfiguration is XNL-complete.

Recall that Theorem 6 then implies the XNL-completeness results for the other variants of Binary Timed Independent Set Reconfiguration. A similar proof for the dominating set variant can be found in Appendix C.2.

**Proof of Theorem 14.** We first show that Binary Timed Partitioned TS-Independent Set Reconfiguration is in XNL, that is, it can be modelled by a Nondeterministic Turing Machine using a work tape of size \(O(k \log n)\). One can store the current independent set of size \(k\) on the work tape and allow only transitions between an independent set \(I\) to an independent set \(I' = I \setminus \{v\} \cup \{w\}\) if \(vw \in E, v \in I\) and \(w \notin I\). We can generate the possible independent sets adjacent to a given independent set \(I\) and keep track of the number of moves on a work tape of size \(O(k \log n)\). Since the number of independent sets of size \(k\) is at most \(n^k\), and a shortest sequence consists of distinct independent sets, we may assume that \(\ell \leq n^k\).

To prove that Binary Timed Partitioned TS-Independent Set Reconfiguration is XNL-hard, we give a reduction from Long Partitioned Positive Chain Satisfiability. The construction is similar (but more cumbersome) way as the one in [1, Theorem 4.11].

Let \((q, r, F, P^1, \ldots, P^k)\) be an instance of Long Partitioned Positive Chain Satisfiability. We will create an instance \(\Gamma\) of Binary Timed Partitioned TS-Independent Set Reconfiguration with \(3k + 1\) token sets. The idea is to represent the choice of which variables \(x_j(t)\) are set to true with variable gadgets, and to create a clause checking gadget that verifies that \(F(x_1(t), \ldots, x_q(t), x_1(t+1), \ldots, x_q(t+1))\) is true. The time counter gadget has \(k\) tokens, which together represent the integer \(t\) using the time constraint, we ensure that we have the follow a very specific sequence of moves, and can therefore not change which \(x_j(t)\) is true after we passed an independent set that made a choice for this.

**Time counter gadget.** We create \(k\) time tokens who have its token set within the time counter gadget, where the positions of these tokens represent an integer \(t \in [1, r]\) with \(r \leq q^k\). We create \(k\) timers, consisting each of \(4q\) vertices. For \(i \in [1, k]\), the timer \(t^i\) is a cycle on vertices \(t_{i0}, \ldots, t_{iq-1}\), which forms a token set for one of the time tokens. If the time tokens are on the vertices \(t_{i0}, \ldots, t_{ik}\), then this represents the current time as

\[
\ell = \sum_{i=1}^{k} (\ell_i \mod q) q^{-i-1}.
\]

Henceforth, we will silently assume \(t\) to be given by the position of the time tokens as specified above. How these timers are connected such that they work as expected will be discussed later.
Variable gadget. We create four sets $A = \{a_1, \ldots, a_q\}$, $B = \{b_1, \ldots, b_q\}$, $C = \{c_1, \ldots, c_q\}$ and $D = \{d_1, \ldots, d_q\}$ that all contain $q$ vertices. These sets will be used to model which variables $x_j^{(t)}$ are chosen to be true. We partition the sets in the same way as the variables, setting $A^i = \{a_j : j \in P^i\}$ for all $i \in [1,k]$ and defining $B^i$, $C^i$ and $D^i$ similarly.

For all $i \in [1,k]$, we make $(A^i, B^i)$ and $(C^i, D^i)$ complete bipartite graphs, adding the edges $a_j b_j$ and $c_j d_j$ for all $j, j' \in P^i$. We specify $A^i \cup B^i$ and $C^i \cup D^i$ as token sets, and refer to the corresponding $2k$ tokens as variable tokens. The first set is used to model the choice of the true variable $x_j^{(t)}$ for $j \in P^i$ for all odd $t$, whereas the second partition models the same for any even $t$.

We will enforce the following. Whenever we check whether all the clauses are satisfied, we will either restrict all tokens of $A \cup B$ to be in $A$, or restrict all to be in $B$. Whenever we have to choose a new set of true variables for $t$ odd, we move all tokens from $A$ to $B$ (or the other way around). This movement takes exactly $k$ steps. The same holds for even $t$ and the sets $C$ and $D$.

Clause checking gadget. The clause checking gadget exists of four parts, called $AC$, $BC$, $BD$ and $AD$, named after which pair of sets we want the variable tokens to be in. All the vertices of the clause checking gadget form a token set, and we refer to the corresponding token as the clause token. The token will traverse the gadget parts in the order $AC \rightarrow BC \rightarrow BD \rightarrow AD \rightarrow AC \rightarrow \ldots$. If the token is on $AC$, we require the variable tokens to be in $A$ and $C$ and we then check whether the clauses hold for the given choice of variables. The other parts are constructed likewise. For an example we refer to Figure 2.

![Figure 2](image)

Figure 2 Sketch of part of the construction of Theorem 14. Given are the two variable gadgets for $A^i \cup B^i$ and $C^i \cup D^i$, the AC part of the clause checking gadget with one clause: $C_1 = \{x_1^{(t)}, x_2^{(t+1)}\}$, where $t$ is odd. Hence $v_1^1$ checks whether $a_1$ is set to true and $v_2^1$ checks whether $c_2$ is set to true.

We now give the construction of this gadget. We create a vertex, $T^{AC}$ that is connected to all $b \in B$. This ensures that if the clause token is on $T^{AC}$, all tokens from $A \cup B$ are on vertices in $A$, yet tokens will be able to move from vertices in $D$ to vertices in $C$.

Suppose $F = C_1 \land \cdots \land C_S$ with each $C_i$ a disjunction of literals. Let $s \in \{1, S\}$ and let $C_s = y_1 \lor \cdots \lor y_h$, be the $s$th clause. We create a vertex $v_h^s$ for all $h \in [1, H_s]$. All $v_h^s$ are connected to all vertices in $B$ and $D$, which ensures that whenever the clause token is on some $v_h^s$, all variable tokens to be on vertices in $A$ and $C$ and prohibits these variable tokens to move.

Let $h \in [1, H_s]$ and let $j \in [1, q]$ be such that $y_h$ is the $j$th variable. We ensure that the clause token can only be on $v_h^s$ if the corresponding $x_j^{(t)}$ is modelled as true, that is, the corresponding variable token is on the vertex $a_j$ or $c_j$ (depending on the parity of $t$). To
ensure this, we connect \(v^*_h\) to all variables in \(A^i \setminus \{a_j\}\) if \(t\) is odd and to all variables in \(C^i \setminus \{c_j\}\) if \(t\) is even, where \(i \in [1, k]\) satisfies \(j \in P^i\).

We add edges such that \(\{v^*_h\}_{b \in [1, H_i]}, \{v^{s+1}_h\}_{b \in [1, H_{i+1}]})\) forms a complete bipartite graph for all \(s \in [1, S - 1]\). We connect \(T^AC\) to all \(v^*_h\) and we connect all \(v^*_h\) to \(T^BC\), the first vertex of the next gadget. Whenever we move the clause token from \(T^AC\) to \(T^BC\), we have to traverse a vertex \(v^*_h\) for each clause \(C_s\), which ensures that the literal \(y_h\) in the clause \(C_s\) is set to true according to the variable tokens.

The gadget parts for \(BC, BD\) and \(AD\) are constructed likewise. We omit the details.

**Connecting the time counter gadget.** We now describe how to connect the vertices in the time counter gadget to those in the clause checking gadget. In the first timestep, we create the following edges for \(z \in [0, 4q - 1]\):

- \(T^AC_i^1\) when \(z \equiv 2 \) or \(z \equiv 3 \) mod 4,
- \(T^BC_i^1\) when \(z \equiv 3 \) or \(z \equiv 0 \) mod 4,
- \(T^BD_i^1\) when \(z \equiv 0 \) or \(z \equiv 1 \) mod 4,
- \(T^AD_i^1\) when \(z \equiv 1 \) or \(z \equiv 2 \) mod 4,

This ensures that we can only move the first time token from \(t^0_i\) to \(t^1_i\) if the clause token is on \(T^AC\), and that we cannot put the clause token on \(T^BC\) before having moved the time token. To enforce that the time token moves when the clause token is at \(T^AC\), we add edges between any \(v^*_h\) vertex in this path and all \(t^1_i\) with \(z \equiv 1 \) mod 4. The edges are created in a similar manner for the paths following \(T^BC, T^BD\) and \(T^AD\).

When the first time token has made \(q\) steps, we allow the second time token to move 1 step forward. For \(i \in [2, k]\) we add all edges \(t^0_i t^{i+1}_i\), except for the following \(y, z \in [0, 4q - 1]\):

- \(y \equiv 0 \) mod 4 and \(z \in [0, q]\),
- \(y \equiv 1 \) mod 4 and \(z \in [q, 2q]\),
- \(y \equiv 2 \) mod 4 and \(z \in [2q, 3q]\),
- \(y \equiv 3 \) mod 4 and \(z \in [3q, 4q - 1] \cup \{0\}\).

This ensures, for example, that the \((i + 1)\)th gadget token can move from \(t^{i+1}_0\) to \(t^{i+1}_1\) if and only if the \(i\)th time gadget token is on \(t^*_i\).

Finally, we add two sets \(V_{\text{init}}\) and \(V_{\text{fin}}\) of \(2k\) vertices, and add the first set to the initial independent set \(I_{\text{init}}\) and the second to the final independent set \(I_{\text{fin}}\). Each vertex of \(V_{\text{init}}\) is added to the token set of \(A^i \cup B^i\) or \(C^i \cup D^i\) for some \(i \in [1, 2k]\), adding exactly one vertex to each token set, and similarly for \(V_{\text{fin}}\).

We create edges \(uv\) for all \(u \in V_{\text{init}} \cup V_{\text{fin}}\) and \(v\) in the clause checking gadget. We also create two vertices \(c_{\text{init}}\) and \(c_{\text{fin}}\) that are added to the initial and final independent set respectively, and to the token set of the clause token. We make \(c_{\text{init}}\) adjacent to \(T^AC\) and \(c_{\text{fin}}\) to a vertex \(T^{XY}\), where \(X, Y\) depend on the value of \(r\) modulo 4.

The vertices \(c_{\text{init}}\) and \(c_{\text{fin}}\) are adjacent to all vertices in the time gadgets except for those representing the time 0 and \(r\) respectively. The initial independent set also contains the vertices in the time gadget that represent \(t = 0\) and similarly \(I_{\text{fin}}\) contains the vertices that represent \(r\).

**Bounding the sequence length.** We give a bound \(\ell\) on the length of the reconfiguration sequence, to ensure that only the required moves are made. Before moving the time token,
We first move the $2k$ variable tokens into position. We can then move the clause token to $T^{AC}$, move the first time token so that the time represents 1 and after that take $S + 1$ steps to reach $T^{BC}$ (with $S$ the number of clauses in $F$), at which point we can move the first time token one step forward, and we need to move $k$ variable tokens from $A$ to $B$. Because we check exactly $r - 1$ assignments, we need to move the $i$th time counter token exactly $\left\lfloor (r - 1)/q^{k-(i-1)} \right\rfloor$ times. As a last set of moves, we need to move the variable tokens to the set $V_{fin}$, and the clause token to $c_{fin}$ taking another $2k + 1$ steps. Hence, we set the maximum length of the sequence $\ell$ (from the input of our instance of Binary Timed Partitioned TS-Independent Set Reconfiguration) to

$$4k + 2 + (r - 1)(S + k + 1) + \sum_{i=1}^{k} \left\lfloor (r - 1)/q^{k-(i-1)} \right\rfloor.$$ 

We claim that there is a satisfying assignment for our instance of Long Partitioned Positive Chain Satisfiability if and only if there is a reconfiguration sequence from $I_{init}$ to $I_{fin}$ of length at most $\ell$. It is not too difficult to see that a satisfying assignment leads to a reconfiguration sequence (by moving the variable tokens such that they represent the chosen true variables $x_j^{(t)}$ when the time tokens represent time $t$).

Vice versa, suppose that there is a reconfiguration sequence of length $\ell$. This is only possible if the sequence takes a particular form: we need to move the time tokens for $\sum_{i=1}^{k}\left\lfloor (r - 1)/q^{k-(i-1)} \right\rfloor$ steps, and can only do this if we can move the clause token $(r - 1)(S + 1) + 2$ steps. The moves of the clause token forces us to move $k$ variable tokens between $A$ and $B$ and between $C$ and $D$ a total of $(r - 1)$ times, and we need a further $2k$ moves to get these from $V_{init}$ and to $V_{fin}$. In particular, there is no room for moving a variable token from one position in $A$ to another position in $A$, without the “time” having moved 4 places. Therefore, for each $i \in [1,k]$ and $t \in [1,r]$, there is a unique $j$ for which we find a variable token on $a_j \in A^i$, $b_j \in B^i$, $c_j \in C^i$ or $d_j \in D^i$ (which letter $a, b, c$ or $d$ we search for depends on the value of $t$ modulo 4) when the time tokens represent time $t$. This is the variable $x_j^{(t)}$ that we set to true from the $t$th variable set in partition $P^i$.

### 5 Proof of Theorem 4: $W[1]$-membership

We formulate Timed TJ-Independent Set Reconfiguration with the number of tokens and length of the reconfiguration sequence as combined parameter as an instance of Weighted 3-CNF-Satisfiability.

**Weighted 3-CNF-Satisfiability**

**Given:** Boolean formula $F$ on $n$ variables in conjunctive normal form such that each clause contains at most 3 literals; integer $K$.

**Parameter:** $K$.

**Question:** Can we satisfy $F$ by setting exactly $K$ variables to true?

This proves Theorem 4 since Weighted 3-CNF-Satisfiability is $W[1]$-complete [3]. We explain how to adjust it to $W[2]$-membership for the dominating set variant in Appendix C; the main idea of our proof can be applied for several other reconfiguration problems (all that is needed is that the property of the solution set can be expressed as a CNF formula).

**Proof of Theorem 4.** Let $(G = (V, E), I_{init}, I_{fin}, k, \ell)$ be an instance of Timed TJ-Independent Set Reconfiguration. We set $C = (k + 1 + \ell)^2$ and $K = \ell(C + 1) + (\ell + 1)k$. We add the following variables to our Weighted 3-CNF-Satisfiability instance for all $t \in [0, \ell]$:
Parameterized Complexities of Dominating and Independent Set Reconfiguration

We add clauses that are satisfied if and only if the set of true variables corresponds to a correct TJ-reconfiguration sequence from \( I_{\text{init}} \) to \( I_{\text{fin}} \).

We have clauses with one literal that ensure that at time 0, we have the initial configuration: for each \( v \in I_{\text{init}} \), we have a clause \( s_{0,v} \) and for each \( v \not\in I_{\text{init}} \), we have a clause \( \neg s_{0,v} \).

Similarly, we have clauses that ensure that at time \( \ell \), we have the final configuration: for each \( v \in I_{\text{fin}} \), we have a clause \( s_{\ell,v} \) and for each \( v \not\in I_{\text{fin}} \), we have a clause \( \neg s_{\ell,v} \).

All \( m_{i,v}^{(i)} \) are equivalent: for all distinct \( i,j \in [1,C] \) and for all \( t \in [1,\ell] \) and for all distinct \( v,w \in V \), we add the clauses \( \neg m_{i,v}^{(i)} \lor m_{j,w}^{(j)} \lor m_{i,v}^{(i)} \lor \neg m_{j,w}^{(j)} \). For all distinct \( i,j \in [1,C] \) and for all \( t \in [1,\ell] \), we add the clauses \( \neg m_{t,0}^{(i)} \lor m_{t,0}^{(j)} \lor m_{t,0}^{(i)} \lor \neg m_{t,0}^{(j)} \).

We have clauses that ensure that at each time \( t \in [1,\ell] \), at most one move is selected: for any two distinct pairs of distinct vertices \( (v,w) \) and \( (v',w') \), we add the clauses \( \neg m_{t,v,w}^{(i)} \lor \neg m_{t,v',w'}^{(j)} \lor \neg m_{t,v,w}^{(i)} \lor \neg m_{t,v',w'}^{(j)} \).

For \( t \in [1,\ell] \), if the move \( m_{t,v,w}^{(i)} \) is selected, then \( v \) lost a token and \( w \) obtained a token from time \( t-1 \) to time \( t \): \( \neg m_{t,v,w}^{(i)} \lor s_{t-1,v} \lor \neg m_{t,v,w}^{(i)} \lor \neg s_{t-1,w} \lor m_{t,v,w}^{(i)} \lor \neg s_{t,v} \) and \( \neg m_{t,v,w}^{(i)} \lor \neg m_{t,v,w}^{(i)} \lor s_{t,w} \).

For \( t \in [1,\ell] \), tokens on vertices not involved in the move remain in place. For all distinct \( v,w,u \in V \), we add the clauses

\[
\neg m_{t,0}^{(i)} \lor \neg s_{t-1,v} \lor s_{t,v}, \\
\neg m_{t,0}^{(i)} \lor s_{t-1,v} \lor \neg s_{t,v}, \\
\neg m_{t,v,u}^{(i)} \lor \neg s_{t-1,u} \lor s_{t,u} \text{ and } \\
\neg m_{t,v,u}^{(i)} \lor s_{t-1,u} \lor \neg s_{t,u}.
\]

We record if a token was added to a vertex: for all \( t \in [1,\ell] \) and \( v \in V \), we add the clause \( s_{t-1,v} \lor \neg s_{t,v} \lor a_{t,v} \). This in particular ensures that \( a_{t,v} \) is true when \( m_{t,v,w}^{(i)} \) is true for some vertex \( w \neq v \).

No move happened if and only if no token was added: for all \( t \in [1,\ell] \) we add the clauses \( \neg a_{t,v} \lor m_{t,0}^{(i)} \) and \( \neg a_{t,v} \lor m_{t,0}^{(i)} \).

At most one \( a_{t,v} \) is set to true, implying that at most one taken gets added at each time step: for all \( t \in [1,\ell] \) and distinct \( v,w \in V \), we add the clauses \( \neg a_{t,v} \lor \neg a_{t,w} \) and \( \neg a_{t,v} \lor \neg a_{t,w} \).

Finally, we check whether the current set forms an independent set: for all edges \( vw \in E(G) \) and \( t \in [0,\ell] \), we add the clause \( \neg s_{t,v} \lor \neg s_{t,w} \).

If there is a TJ-independent set reconfiguration sequence \( I_{\text{init}} = I_0, \ldots, I_T = I_{\text{fin}} \) with \( T \leq \ell \), then we set \( s_{t,v} \) to true and only if \( v \in I_t \) for \( t \in [0,T] \). For all \( t \in [T,\ell] \), we set \( s_{t,v} \) to true if and only if \( v \in I_T \).

Let \( t \in [1,\ell] \). If \( I_t = I_{t-1} \), we set \( a_{t,0} \) to true and \( m_{t,0}^{(i)} \) to true for all \( i \in [1,C] \). Otherwise, we find \( I_t = I_{t-1} \setminus \{v\} \cup \{w\} \) for some \( v,w \in V \) and we set \( m_{t,0}^{(i)} \) and \( a_{t,v} \) to true for all
\[ i \in [1, C]. \] All other \( m^{(i)}_{t,\star} \) are set to false. This gives a satisfying assignment with exactly \( \ell(C + 1) + (\ell + 1)k = K \) variables set to true.

Suppose now that there is a satisfying assignment with \( K \) variables set to true. At most one \( a_{t,v} \) variable can be true for each \( t \in [1, \ell] \). Exactly \( k \) variables of the form \( s_{t,v} \) are set to true by the initial condition. If there are \( k' \) tokens true at time \( t \), then there are at most \( k' + 1 \) tokens true at time \( t + 1 \) and so the \( s_{t,v} \) and \( a_{t,v} \) variables together can constitute at most \( (k + \ell + 1)\ell \leq C - 1 \) true variables. Therefore, there must be strictly more than \( (C + 1)(\ell - 1) \) variables of the form \( m^{(i)}_{t,\star} \) that are set to true. Since \( m^{(i)}_{t,\star} \) must take the same value as \( m^{(j)}_{t,\star} \), there must be at least \( \ell \) variables of the form \( m^{(1)}_{t,\star} \) that are set to true. There can be at most one per time step \( t \), and so there is exactly one per time step. We consider the TJ-independent set reconfiguration sequence \( I_{\text{init}} = I_0', \ldots, I_{T'} = I_{\text{fin}} \) where for \( t \in [1, \ell] \) we define \( I_t' = I_{t-1}' \) if \( m_{t,\emptyset} \) is true, and \( I_t' = I_{t-1}' \setminus \{v\} \cup \{w\} \) if \( m^{(1)}_{t,v,w} \) is true. The subsequence \( I_{\text{init}} = I_0, \ldots, I_T = I_{\text{fin}} \) obtained by removing \( I_t' \) if \( I_t' = I_{t-1}' \), is now a valid TJ-independent set reconfiguration sequence.

\[ \diamond \]

## Conclusion

We showed that for independent set reconfiguration problems parameterized by the number of tokens, the complexity may vary widely depending on the way the length \( \ell \) of the sequence is treated. If no bound is given, then we ask for the existence of an undirected path in the reconfiguration graph \[5\] and indeed the problem is XL-complete. If \( \ell \) is given in binary, then we may in particular choose it larger than the maximum number of vertices in the reconfiguration graph, and so this problem is at least as hard as the previous. We show it to be XNL-complete. When \( \ell \) is given in unary, it is easier to have a running time polynomial in \( \ell \), and indeed the problems becomes XNLP-complete. When \( \ell \) is taken as parameter, the problem is \( W[1] \)-complete.

On the other hand, switching the rules of how the tokens may move does not affect the parameterized complexity, and the results for dominating set reconfiguration are also similar. It would be interesting to investigate for which graph classes switching between token jumping and token sliding does affect the parameterized complexities. We give an explicit suggestion below.

\[ \blacktriangleright \textbf{Problem 15.} \text{ For which graphs } H \text{ is } TJ-\text{Independent Set Reconfiguration equivalent to TS-Independent Set Reconfiguration under pl-reductions for the class of graphs with no induced } H? \]

The answer might also differ for Independent Set Reconfiguration and Dominating Set Reconfiguration. We remark that TJ-Clique Reconfiguration and TS-Clique Reconfiguration have the same complexity for all graph classes \[7\].

5. The reconfiguration graph has the possible token configurations as vertex set, and there is an edge between two configurations if we can go from one to the other with a single move.
A Background on XL-, XSL- and XNL-complete Problems

In this appendix, we discuss why ACCEPTING LOG-SPACE SYMMETRIC TURING MACHINE is XL-complete and why ACCEPTING LOG-SPACE NONDETERMINISTIC TURING MACHINE is XNL-complete. To do this, we first introduce the original XSL- and XNL-complete problems. We then discuss why these problems are equivalent to ACCEPTING LOG-SPACE SYMMETRIC TURING MACHINE and ACCEPTING LOG-SPACE NONDETERMINISTIC TURING MACHINE respectively. Finally, we discuss why the complexity class XL is equal to XSL. Everything in this appendix was known previously and the proofs are included for completeness.

A.1 XNL- and XSL-complete Problems

Recall that a Nondeterministic Turing Machine (NTM) with one work tape is a 5-tuple $(\mathcal{S}, \Sigma, T, s_{\text{start}}, A)$, where $\mathcal{S}$ is a finite set of states, $\Sigma$ is the alphabet, $T$ is the set of transitions, $s_{\text{start}}$ is the start state and $A$ is the set of accepting states.
Normally, Turing Machines are defined to have an input \( \alpha \in \Sigma^* \) on the input tape. The input tape is (in contrast with the work tape) immutable. A transition \( T \in \mathcal{T} \) is then a tuple of the form \( (p, \Delta_{\text{work}}, \Delta_{\text{inp}}, q) \), where \( \Delta_{\text{work}} \) and \( \Delta_{\text{inp}} \) are both tape triples describing the work tape and input tape respectively. As the input tape is immutable, any \( \Delta_{\text{inp}} \) will be of the form \( (e, \delta, e) \) with \( \delta \in \{-1, 0, 1\} \). We say that \( \alpha \in \Sigma^* \) is accepted by an NTM \( M \) if the computation of \( M \) with \( \alpha \) on the input tape ends in an accepting state.

This leads us to the following problem that is complete for the complexity class XNL:

**Input Accepting Binary Log-Space Nondeterministic Turing Machine**

Given: An NTM \( M = (S, \Sigma, \mathcal{T}, s_{\text{start}}, A) \) with \( \Sigma = \{0, 1\} \), a work tape with \( k \log n \) cells and input \( \alpha \in \Sigma^* \).

Parameter: \( k \).

Question: Does \( M \) accept \( \alpha \)?

**Changing the alphabet.** Note that we can rewrite any Binary Nondeterministic Turing Machine \( M \) with binary alphabet and \( k \cdot \log n \) cells on the work tape, to an equivalent NTM \( M' \) with \( \Sigma' = [1, n] \) and \( k \) cells on the work tape. This can be done by splitting the work tape into \( k \) pieces of size \( \log n \), viewing each piece as one character \( \sigma \in \Sigma \). The transitions can then be re-written accordingly. The equivalence goes both ways: for any cell on the work tape of \( M' \), we can take \( \log(n) \) bits to represent its bit encoding on the work tape of \( M \). Whenever a transition changes a cell of \( M' \), a path of \( \log n \) transitions is created for \( M \) that changes each bit of the resulting representation accordingly. Hence, the following problem is equivalent (under pl-reductions) to **Input Accepting Binary Log-Space Nondeterministic Turing Machine**.

**Input Accepting Log-Space Nondeterministic Turing Machine**

Given: An NTM \( M = (S, \Sigma, \mathcal{T}, s_{\text{start}}, A) \) with \( \Sigma = [1, n] \), a work tape with \( k \) cells and input \( \alpha \in \Sigma^* \).

Parameter: \( k \).

Question: Does \( M \) accept \( \alpha \)?

**Removing the input tape.** We now argue that this problem is equivalent to **Accepting Log-Space Nondeterministic Turing Machine**. The idea is to track the position of the input tape head by creating extra states. To do this, replace any state \( p \in S \) by states \( p^j \) for all \( j \in [1, |\alpha|] \). We also replace any transition \( \tau \in \mathcal{T} \) by transitions \( \tau^j \), for all \( j \) such that \( \alpha_j \) has the required symbols on the input tape. If, for example, \( \tau \) moves the input tape head to the right and transitions from state \( p \) to state \( q \), then the transition \( \tau^j \) goes from state \( p^j \) to state \( q^{j+1} \). This increases the number of states and transitions with a factor \( |\alpha| \). Since \( \alpha \) is part of the original input, this increases the size of the NTM by a factor that is polynomial in the size of the input.

**Symmetric Turing Machines.** The following problem is complete for complexity class XSL:

**Input Accepting Binary Log-Space Symmetric Turing Machine**

Given: An STM \( M = (S, \Sigma, \mathcal{T}, s_{\text{start}}, A) \) with \( \Sigma = \{0, 1\} \), a work tape with \( k \log n \) cells and input \( \alpha \in \Sigma^* \).

Parameter: \( k \).

Question: Does \( M \) accept \( \alpha \)?
All transformations from previous paragraphs can be applied to Symmetric Turing Machines. We conclude that **Accepting Log-Space Symmetric Turing Machine** is XSL complete.

### A.2 XL = XSL

Reingold [13] describes a log-space algorithm solving a problem called USTCON. This problem asks, given an undirected graph $G$ and two of its vertices $s$ and $t$, whether $s$ and $t$ are connected. We briefly explain why this result implies $L = SL$.

We note that $L \subseteq SL$, because any Deterministic Turing Machine (DTM) can be modelled by a Symmetric Turing Machine (STM) with the same work tape size. For the other direction, one can view the configurations of an STM $M$ as vertices of a graph $G$ and the allowed transformations between configurations as its edges. Because $M$ is symmetric, these edges always go both ways, so we can view $G$ as an undirected graph. Let $C_{\text{start}}$ be the starting configuration and $C_{\text{acc}}$ be the accepting configuration of $M$. (We may assume that there exists only one accepting configuration by adding a path of $O(k \log n)$ states and transition after the accepting state, setting all the symbols on the work tape to 1 and moving the tape head to the first position.) Then $M$ accepts if and only if $C_{\text{start}}$ and $C_{\text{acc}}$ are connected in $G$.

We can apply the algorithm of Reingold for USTCON, to compute whether $C_{\text{start}}$ and $C_{\text{acc}}$ are connected in $G$ in space $O(\log |V|)$, where $|V|$ is the number of vertices of $G$. The number of different configurations (hence the number of vertices for the corresponding graph) is at most polynomial in $n$, the size of $M$. (The configurations are specified by the contents of the work space, the position of the head and the current state.) This implies Reingold’s algorithms runs in space $O(\log n)$, implying that a DTM can decide whether $M$ accepts in space $O(\log n)$.

These ideas also apply to the complexity classes XSL and XL; $XL \subseteq XSL$ because any DTM can be modelled by an STM with the same work tape size. For the other direction, we create a graph $G$ just like before. There are then $n^k$ different possibilities for the work tape, $n$ different states and $k$ different tape head positions. Therefore the number of vertices of $G$ is upperbounded by $n^{O(k)}$. We apply the algorithm of Reingold to compute whether $C_{\text{start}}$ and $C_{\text{acc}}$ are connected in $G$ in space $O(k \log n)$. Therefore, a DTM with $O(k \log n)$ space can compute this, implying XSL $\subseteq XL$.

Therefore, XL=XSL and any XSL-complete problem is also XL-complete. This concludes the proof of Theorem 7.

### B Long Chained Satisfiability

In this Appendix, we prove Theorem 13 which states that **Long Partitioned Positive Chain Satisfiability** is XNL-complete.

**Proof of Theorem 13** We first show that the problem is in XNL: an instance of **Long Partitioned Positive Chain Satisfiability** can be simulated by a Nondeterministic Turing Machine with a work tape that can contain $3k$ symbols from an alphabet of size $q$. Of these, $k$ symbols are used to represent our ‘current time’, an integer $t \in [1, r]$ (where $r \leq q^k$). For each $i \in [1, k]$, we use two symbols from $[1, q]$ to represent which variables from $\{x_j^{(t)} : j \in P_i\}$ and $\{x_j^{(t+1)} : j \in P_i\}$ are set to true, where $t$ is the symbol representing the ‘current time’. Finally, we create the transitions in such a way that if $F(x_1^{(t)}, \ldots, x_q^{(t)}, x_1^{(t+1)}, \ldots, x_q^{(t+1)})$ is true, the ‘current time’ goes from $t$ to $t + 1$ (until we
reach \( r \), which brings us to the accepting state) and the \( k \) corresponding symbols are renewed. If the formula is false, we transition to the rejecting state.

Suppose now that we are given an instance of Accepting Log-Space Nondeterministic Turing Machine. Let \( \mathcal{M} = (S, \Sigma, \mathcal{T}, s_{\text{start}}, A) \) be the NTM of a given instance, with \( A = \{ s_{\text{acc}} \}, \Sigma = [1, n] \) and a work tape of \( k \) cells. We may again assume that \( \mathcal{M} \) only accepts if the symbol 1 is in every cell of the work tape and the head is at the first cell.

Recall that configurations of an NTM \( \mathcal{M} \) are \( k + 2 \) tuples describing the state, work tape and head position of \( \mathcal{M} \) (see Definition [8]).

There are at most \( r = k|S| |\Sigma|^k \) different configurations of \( \mathcal{M} \). Any shortest path from the starting configuration to an accepting configuration therefore has length at most \( r \) and so we do not have to explore any simulations of the machines which take more transitions than that.

We create four sets of variables, which ‘simulate the configuration of the machine’:

- \( h_{t,p} \) for \( t \in [1, r] \) and \( p \in [1, k] \) represents the position \( p \) of the tape head at time \( t \);
- \( z_{t,s} \) for \( t \in [1, r] \) and \( s \in S \) represents the state \( s \) of the machine at time \( t \);
- \( w_{t,p,\sigma} \) for \( t \in [1, r], p \in [1, k], \sigma \in \Sigma \) represents that position \( p \) of the work tape has symbol \( \sigma \) at time \( t \);
- \( d_{t,\tau} \) for \( t \in [1, r] \) and \( \tau \in \mathcal{T} \) represents that the machine employs transition \( \tau \) from time \( t - 1 \) to \( t \).

For each \( t \in [1, r] \), the machine has exactly one state, the head one position, each work tape position one symbol and the machine takes exactly one transition. We ensure this by partitioning the variables appropriately. Namely, set \( k' = k + 3 \) to be the number of parts and \( q = k + |S| + k|\Sigma| + |\mathcal{T}| \) the number of variables involved. For each \( t \in [1, r] \), we create the parts

\[
\begin{align*}
\{ h_{t,p} : p \in [1, k] \},
\{ z_{t,s} : s \in S \},
\{ w_{t,p,\sigma} : \sigma \in \Sigma \} \quad \text{for all } p \in [1, k],
\{ d_{t,\tau} : \tau \in \mathcal{T} \}.
\end{align*}
\]

This defines the partition of \([1, q]\). We create the following formulas which verify that the variables behave as we wish.

- When a transition \( \tau \in \mathcal{T} \) takes place from time \( t - 1 \) to time \( t \), then at time \( t \) the work tape, state and head must take the values specified by the transition (this may depend on the current position of the head). For each \( t \in [1, r] \) and transition \( \tau \in \mathcal{T} \) that changes state \( s \) to \( s' \) and symbol \( a \) to \( b \) and moves the head to the right, we add the formulas

\[
\begin{align*}
\neg d_{t,\tau} \lor z_{t,s'},
\neg d_{t,\tau} \lor \neg h_{t-1,p} \lor w_{t,p,b} & \text{ for each } p \in [1, k], \text{ and }
\neg d_{t,\tau} \lor \neg h_{t-1,p} \lor h_{t,p+1} & \text{ for each } p \in [1, k].
\end{align*}
\]

The first formula states that when \( \tau \) is invoked from time \( t - 1 \) to time \( t \), the state becomes \( s' \) at time \( t \). The second and third ensure that if the head is on position \( p \) at time \( t - 1 \) when \( \tau \) is invoked, then the symbol on position \( p \) becomes \( b \) at time \( t \) and the head is in position \( p + 1 \) at time \( t \). Transitions that move the head to the left or leave it on the same place are handled analogously.

- At time \( t - 1 \), the ‘initial conditions’ of the transition that takes place need to be true. For each \( t \in [1, r] \) and transition \( \tau \in \mathcal{T} \) that changes state \( s \) to \( s' \) and symbol \( a \) to \( b \), we
add the formulas

$$-d_{t,r} \lor z_{t-1,s}, \text{ and}$$

$$-d_{t,r} \lor -h_{t-1,p} \lor w_{t-1,p,a} \text{ for each } p \in [1,k].$$

- Only the work tape position that the tape head is on can change. For each $t \in [1,r]$, and distinct head positions $p, p' \in [1,k]$, we add the formulas

$$-h_{t-1,p} \lor -w_{t-1,p',\sigma} \lor w_{t,p',\sigma} \text{ for all } \sigma \in \Sigma.$$  

This formula states if at time $t - 1$, the head is at position $p$ and the work tape has symbol $\sigma$ at position $p' \neq p$, then the work tape still has symbol $\sigma$ at position $p'$ at time $t$.

- For the starting state $s_{\text{start}} \in S$ of the machine, we add a single formula of the form $z_{0,s_{\text{start}}}$. We similarly initialise the work tape and head position appropriately. Finally, we add a transition from the accepting state $s_{\text{acc}}$ to itself, and check whether at time $r$ we are in $s_{\text{acc}}$ by adding the formula $z_{r,s_{\text{acc}}}$.

We need two further adjustments in order to have an instance of Long Partitioned Positive Chain Satisfiability. First of all, we want to have a single formula $F$ that is used for all variable sets, but currently there are formulas $F_0$ and $F_2$ that we only wish to be true for the initial and final set of variables respectively (namely, those describing the initial and final configurations of the machine). To obtain this, we ‘simulate a binary counter’.

Let us assume for convenience that $R = \log_2 (r + 1)$ is an integer. A number $t \in [0,r]$ can be represented ‘in base $k$’ as

$$t = \sum_{j=0}^{R-1} b_j k^j$$

with $b_j = b_j(t) \in [0,k-1]$. (When $R$ is not an integer, ‘the last’ $b_j$ will have a smaller domain.) We increase the number of parts $k'$ by $k$ and the number of variables $q$ by $Rk$. A new variable $b_{t,j,i}$ (with $j \in [0,R-1]$ and $i \in [0,k-1]$) models whether $b_j(t) = i$.

For each $t \in [1,r]$, $\{b_{t,j,i} : i \in [0,k-1]\}$ forms a part. For all clauses $C_0$ in $F_0$ and $C_2$ in $F_2$, we add the two formulas

$$\left( \bigvee_{j=0}^{R-1} -b_{t,j,0} \right) \lor C_0,$$

$$\left( \bigvee_{j=0}^{R-1} -b_{t,j,k-1} \right) \lor C_2.$$  

We now enforce ‘the counter’ to move up by one in each time step, such that if there is a satisfying assignment, $\land_{j=0}^{R} b_{t,j,0}$ holds if and only if $t = 0$ and $\land_{j=0}^{R} -b_{t,j,k-1}$ holds if and only if $t = r$. This is done by adding the following formulas for all $j \in [1,R-1]$ and $i \in [0,k-1]$

$$-b_{t,0,i} \lor b_{t+1,0,i+1 \mod k},$$

$$(-b_{t,j,i} \lor b_{t,j-1,k-1}) \lor b_{t+1,j,i},$$

$$(-b_{t,j,i} \lor -b_{t,j-1,k-1}) \lor b_{t+1,j,i+1 \mod k},$$

$$\left( \bigvee_{j=0}^{R-1} -b_{t,j,0} \right) \lor \left( \bigvee_{j=0}^{R-1} -b_{t+1,j,0} \right) .$$
The last formula ensures that we can never let the counter go from \(r\) to 0, which ensures that the only way to move up the counter \(r + 1\) times is to start at 0 for \(t = 0\) and end at \(r\) at \(t = r\).

Secondly, the occurrence of all literals must be positive. We can ensure this by replacing each occurrence of a negative literal by a requirement that one of the other variables in its part must be true, e.g. \(\lor_{s' \neq s} z_{t,s}\) has the same logical meaning as \(\neg z_{t,s}\) since exactly one variable from \(\{z_{t,s'} : s' \in S\}\) is known to be true.

\[\square\]

## C Dominating Set Reconfiguration

In this appendix, we prove all results of Theorem 5. First we prove Dominating Set Reconfiguration to be XL-complete, next we prove Binary Timed Dominating Set Reconfiguration to be XNL-complete. We finish with proving that Timed Dominating Set Reconfiguration, parameterized moreover by the length of the reconfiguration sequence, is \(W[2]\)-complete.

### C.1 XL-completeness

We prove Partitioned TS-Dominating Set Reconfiguration to be XL-complete. Note that Theorem 6 implies the same complexity for all mentioned variants Dominating Set Reconfiguration of (partitioned) token jumping/sliding.

\[\blacktriangleright\textbf{Theorem 16.} \text{Partitioned TS-Dominating Set Reconfiguration is XL-complete.}\]

\[\textbf{Proof.} \text{The problem is in XL by similar arguments as with Partitioned TS-Independent Set Reconfiguration as it can be simulated with an STM using } O(k \log n) \text{ space.}\]

We prove the problem to be XL-hard by giving a reduction from Accepting Log-Space Symmetric Turing Machine. The reduction is almost identical to the reduction in Theorem 9, therefore we will not discuss correctness of the construction and only give a short description.

Let \( M = (S, \Sigma, \mathcal{T}, s_{\text{start}}, A) \) be the STM of a given instance, with \( A = \{s_{\text{acc}}\} \), \( \Sigma = [1, n] \) and work tape of \( k \) cells. We create an instance \( \Gamma \) of Partitioned TS-Dominating Set Reconfiguration with \( k' = k + 2 \) tokens, so one token more than in the reduction of Theorem 1.

#### Tape gadgets.
For each work tape cell \( i \in [1, k] \), we create a tape gadget consisting of \( n + 2 \) vertices: \( \{v^1_i, \ldots, v^n_i, x^i, y^i\} \). These vertices form a token set. We add edges \( x^i v^\sigma_i \) and \( y^i v^\sigma_i \) for all \( \sigma \in \Sigma = [1, n] \).

#### State vertices.
We create a state vertex \( p^i \) for each state \( p \in S \) and all head positions \( i \in [1, k] \). We add edges \( p^i v^\sigma_i \) for all \( i' \in [1, k] \) and all \( \sigma \in \Sigma \).

#### Transition vertex.
As in the proof of Theorem 1, we create a path of three transition vertices for each allowed transition between two state vertices. We add edges between all \( v^\sigma_i \) vertices and all state and transition vertices (for all \( i \in [1, k] \)), unless specified otherwise.

In order to ensure a token can only be on \( \tau_{ab}^i \) when the token of the \( i \)th tape gadget is on the vertex that represents the symbol \( a \), we remove the edge \( \tau_{ab}^i v^a_i \). For the \( i \)th tape gadget, now all vertices except for \( x^i, y^i \) and \( v^a_i \) are dominated by \( \tau_{ab}^i \), hence the token must be on \( v^a_i \). Similarly, we remove the edge \( \tau_{ab}^i v^{a+1}_i \), as well as edges \( \tau_{cd}^i v^c_i \) and \( \tau_{cd}^i v^{d+1}_i \). When the
token is on the shift vertex \(\tau_{\text{shift}}^i\), the dominating set should be allowed to change the tokens in the \(i\)th and \((i + 1)\)th tape gadgets. Therefore, we add edges \(\tau_{\text{shift}}^i \cdot x^i\) and \(\tau_{\text{shift}}^i \cdot x^{i+1}\), such that the token is able to slide to \(y^i\) and \(y^{i+1}\).

One of the tokens, called the ‘state token’, gets the set of all transition and state vertices as its token set. The position of the state token simulates the state of \(\mathcal{M}\), the position of the head, and the transitions \(\mathcal{M}\) takes.

**Dominating vertex.** We create a token set, consisting out of one vertex \(z_{\text{dom}}\). This vertex is connected to all state and transition vertices. As \(z_{\text{dom}}\) is, by construction, in any dominating set, it allows us to assume that all state and transition vertices are dominated.

**Initial and final dominating sets** Recall that \(s_{\text{start}}\) is the starting state of \(\mathcal{M}\). We let the initial dominating set be \(D_{\text{init}} = \{s_{\text{start}}\} \cup \{z_{\text{dom}}\} \cup \left(\bigcup_{i=1}^k \{v_i\}\right)\), corresponding to the initial configuration of \(\mathcal{M}\). Let the final dominating set be \(D_{\text{fin}} = \{s_{\text{acc}}\} \cup \{z_{\text{dom}}\} \cup \left(\bigcup_{i=1}^k \{v_i\}\right)\), where \(s_{\text{acc}}\) is the accepting state of \(\mathcal{M}\). We note that \(D_{\text{init}}\) and \(D_{\text{fin}}\) are dominating sets.

Let \(\Gamma\) be the created instance of \textit{Partitioned TS-Dominating Set Reconfiguration}. Because of almost identical arguments as in the proof of Theorem 9, \(\Gamma\) is a yes-instance if and only if \(\mathcal{M}\) accepts.

### C.2 XNL-completeness

We prove that \textit{Binary Timed TS-Dominating Set Reconfiguration} is XNL-complete. We note that the problem is in XNL, because it can be simulated by an NTM using \(O(k \log n)\) space.

We prove the problem to be XNL-hard by giving a reduction from \textit{Long Partitioned Positive Chain Satisfiability}. The reduction is very similar to the reduction in Theorem 14. Therefore, we will omit details and only give a short description.

Let \((q, r, F, P^1, \ldots, P^k)\) be an instance of \textit{Long Partitioned Positive Chain Satisfiability}. We create an instance \(\Gamma\) of \textit{Binary Timed TS-Dominating Set Reconfiguration} with \(3k + 2\) token sets.

**Variable gadget.** We create four set \(A = \{a_1, \ldots, a_q\}\), \(B = \{b_1, \ldots, b_q\}\), \(C = \{c_1, \ldots, c_q\}\) and \(D = \{d_1, \ldots, d_1\}\) that all contain \(q\) vertices. We partition the sets in the same way as the variables, setting \(A' = \{a_j : j \in P^i\}\) for all \(i \in [1, k]\) and defining \(B', C'\) and \(D'\) similarly.

For all \(i \in [1, k]\) we make \((A', B')\) and \((C', D')\) complete bipartite graphs and let \(A' \cup B'\) and \(C' \cup D'\) be token sets. We refer to these \(2k\) tokens as the \textit{variable tokens}.

**Clause checking gadget** The clause checking gadget exists of four parts, called \(AC\), \(BC\), \(BD\) and \(AD\). All the vertices of the clause checking gadget form a token set, and we refer to the corresponding token as the \textit{clause token}. We give a construction of the \(AC\) part, the other parts can be constructed likewise.

We create two vertices: \(T_{1AC}^1\) and \(T_{2AC}^2\), connected by an edge. \(T_{1AC}^1\) will allow the variable tokens to move, and \(T_{2AC}^2\) checks if the variable gadget tokens are on vertices in \(A\) and \(C\). To accomplish this, we connect \(T_{1AC}^1\) to \textit{all} vertices in the variable gadgets, allowing movement of the tokens. With \(T_{2AC}^2\) we check if the tokens are only on vertices in \(A\) and \(C\), by adding edges \(T_{iAC}^2 a_j\) and \(T_{iAC}^2 c_j\) for all \(j \in [1, q]\). The vertices in \(B\) and \(D\) must then be dominated by vertices in \(A\) and \(C\) respectively.
Suppose \( F = C_1 \land \cdots \land C_s \) with each \( C_i \) a disjunction of positive literals. Let \( s \in [1, S] \) and let \( C_s = y_1 \lor \cdots \lor y_{H_s} \), be the \( s \)th clause. We create a vertex \( v_h^s \) for all \( h \in [1, H_s] \).

Recall that \( T_2^{AC} \) ensured that all tokens are on vertices in \( A \) and \( C \). Let \( h \in [1, H_s] \) and let \( j \in [1, q] \) be such that \( y_h \) is the \( j \)th variable. We ensure that the clause token can only be on \( v_h^s \) if the corresponding \( x_j^{(t)} \) is modelled as true, by connecting \( v_h^s \) to all \( a_j \) for \( j' \in [1, q] \setminus \{ j \} \) such that \( a_j \) must be in the dominating set whenever \( v_h^s \) is (for \( t \) odd). Also, we connect \( v_h^s \) to all \( c \in C \), so that they are dominated.

We add edges such that \( \{(v_h^s)_h \in [1, H_s]\}; \{(v_h^{s+1})_h \in [1, H_{s+1}]\}\) forms a complete bipartite graph for all \( s \in [1, S - 1] \). We connect \( T_2^{AC} \) to all \( v_h^s \) and we connect all \( v_h^s \) to \( T_1^{BC} \).

**Time counter gadget.** We create a time counter gadget, keeping track of the integer \( t \). For each timer \( i \in [1, 6] \) we add \( 4q + 4 \) vertices. From these, the vertices \( t_0^i, \ldots, t_{4q-1}^i \) form a cycle and are a token set for a token. We name the four additional vertices \( \gamma_1^i, \gamma_2^i, \gamma_3^i \) and \( \gamma_4^i \) and these will be the bridge between two consecutive timers \( i - 1 \) and \( i \). We add edges \( t_z^i \gamma_y^i \) for all \( z \in [0, 4q - 1] \) and \( y \in \{1, 2, 3, 4\} \) such that:

\[
\begin{align*}
z &\equiv 0 \mod 4 \text{ and } y \in \{1, 2\}, \\
z &\equiv 1 \mod 4 \text{ and } y \in \{2, 3\}, \\
z &\equiv 2 \mod 4 \text{ and } y \in \{3, 4\}, \\
z &\equiv 3 \mod 4 \text{ and } y \in \{1, 4\}.
\end{align*}
\]

Furthermore, we add edges \( t_z^{i-1} \gamma_y^i \) for all \( z \in [0, 4q - 1] \) and \( y \in \{1, 2, 3, 4\} \) except for the following

\[
\begin{align*}
y &= 1 \text{ and } z \in [0, q - 1], \\
y &= 2 \text{ and } z \in [q, 2q - 1], \\
y &= 3 \text{ and } z \in [2q, 3q - 1], \\
y &= 4 \text{ and } z \in [3q, 4q - 1].
\end{align*}
\]

For \( i = 1 \), we add all edges between \( T_1^{AC}, T_1^{BC}, T_1^{BD}, T_1^{AD} \), and all \( \gamma_y^1 \) for \( y \in [1, 4] \) except for the edges \( T_1^{AC}, \gamma_1^1, T_1^{BC}, \gamma_2^1, T_1^{BD}, \gamma_3^1, T_1^{AD}, \gamma_4^1 \). This construction has the same effect as the time counter gadgets constructed in the proof of Theorem 14.

We add two sets \( V_{\text{init}} \) and \( V_{\text{fin}} \) of \( 2k \) vertices and these to \( D_{\text{init}} \) and \( D_{\text{fin}} \) respectively. Each vertex of \( V_{\text{init}} \) is added to the token set of \( A' \cup B' \) or \( C' \cup D' \) for some \( i \in [1, 2k] \). Similarly for \( V_{\text{fin}} \). We create edges \( uv \) for all \( u \in V_{\text{init}} \cup V_{\text{fin}} \) and \( v \) in the clause checking gadget. We also create two vertices \( c_{\text{init}} \) and \( c_{\text{fin}} \) that are added to \( D_{\text{init}} \) and \( D_{\text{fin}} \) respectively and to the token set of the clause token. We make \( c_{\text{init}} \) adjacent to \( T_1^{AC} \) and \( c_{\text{fin}} \) to \( T_1^{XY} \), where \( X, Y \) depend on the value of \( r \) modulo 4.

The vertex \( c_{\text{init}} \) is adjacent to \( \gamma_1^1 \) and the vertex \( c_{\text{fin}} \) is adjacent to \( \gamma_y^1 \) where \( y \equiv r \) modulo 4. The initial dominating set contains the vertices in the time gadget that represent \( t = 0 \) and similarly \( D_{\text{fin}} \) contains the vertices that represent \( r \).

**Dominating vertex.** The following addition does two things at the same time: ensuring the clause checking gadget vertices and timer cycle vertices are dominated and putting the \( \gamma \) vertices of the time counter gadget in a token set. For this we add one new token set, consisting of all \( \gamma \) vertices and three vertices \( z_{\text{dom}}, z_{\text{gar}} \) and \( z'_{\text{gar}} \). The vertices \( z_{\text{gar}} \) and \( z'_{\text{gar}} \) are only connected to \( z_{\text{dom}} \), implying that \( z_{\text{dom}} \) is in the dominating set at all times. We then add edges between \( z_{\text{dom}} \) and all counter gadget tokens and all \( t_j^i \) for \( j \in [0, 4q - 1] \), to dominate them. We add \( z_{\text{dom}} \) to both \( D_{\text{init}} \) and \( D_{\text{fin}} \).
Bounding the sequence length. We set \( \ell \), the maximum length of the sequence, to
\[
4k + 2 + (r - 1)(S + k + 2) + \sum_{i=1}^{k} \left\lfloor (r - 1)/q^{k-(i-1)} \right\rfloor.
\]
The analysis of this integer is almost identical to that of in Theorem 14, except that one extra step per time step is required to move from \( T_1^{XY} \) to \( T_2^{XY} \).

C.3 \( W[2] \)-membership

The following problem is complete for \( W[2] \) (see e.g. [3]).

**Weighted CNF-Satisfiability**

**Given:** Boolean formula \( F \) on \( n \) variables in conjunctive normal form; integer \( K \).

**Parameter:** \( K \).

**Question:** Can we satisfy \( F \) by setting at most \( K \) variables to true?

We can formulate \( TJ \)-Dominating Set Reconfiguration as Weighted CNF-Satisfiability, by using the same variables and formulas as we did for \( TJ \)-Independent Set Reconfiguration, but changing the last set of formulas that verified whether the solution is an independent set, by the following CNF-formulas that check whether the solution is a dominating set:
\[
\vee_{w \in N[v]} s_{t,w} \text{ for } t \in [0, \ell] \text{ and } v \in V. \text{ Here } N[v] \text{ denotes the set of vertices equal or adjacent to } v.
\]

D (Partitioned) Token Jumping and (Partitioned) Token Sliding Equivalences

In this appendix, we prove Theorem 6 via a sequence of reductions, for the following four rules:

- **Token Sliding (TS):** we can ‘slide’ a token to an empty\(^6\) adjacent vertex.
- **Partitioned Token Sliding:** a partition of the vertices has been given, and we can only ‘slide’ a token to an adjacent vertex within the same token set.
- **Token Jumping (TJ):** we can ‘jump’ a token to an empty vertex.
- **Partitioned Token Jumping:** a partition of the vertices has been given, and we can only ‘jump’ a token to an empty vertex within the same token set.

An overview of the reductions is given in Figure 3.

D.1 Equivalences for Independent Set

**Lemma 17.** There exists a pl-reduction \( f \) from \( TJ \)-Independent Set Reconfiguration to TS-Independent Set Reconfiguration, such that for any instance \( A \) of TJ-Independent Set Reconfiguration with \( k \) tokens, \( A \) admits a reconfiguration sequence of length \( \ell \) if and only if \( f(A) \) admits a reconfiguration sequence of length \( \ell + k + 1 \).

**Proof.** Let \( A = (G, I_{\text{init}}, I_{\text{fin}}, k) \) be an instance of TJ-Independent Set Reconfiguration with \( G = (V, E) \) and \( k = |I_{\text{init}}| \) tokens. We create an instance \( f(A) \) of TS-Independent Set Reconfiguration with \( k \) tokens.

\(^6\) We say a vertex is empty if it has no token on it (i.e. is not part of the independent set).
A TJ-reconfiguration sequence to arrive at \(v\) vertex of \(G\) and there are \(z\) and there are \(z\) tokens and \(z\) clique. At most one vertex of \(G\) for each gadget \(z\) token gadgets, the pigeonhole principle implies that exactly one token must be in each gadget \(V^i\). If a token is placed on \(v^i\), this corresponds to placing the \(i\)th token on vertex \(v\).

We add an edge \(v^i w^j\) for all \(i, j \in [1, k]\) with \(i \neq j\), when \(vw \in E\) or \(v = w\). This results in a graph \(G'\). The edges \(v^i v^j\) ensure that no two gadgets ‘select’ the same vertex and the other edges will ensure that each independent set in \(G'\) corresponds to an independent set in \(G\).

There is still an issue now that for every independent set in \(G\), there are \(k!\) independent sets in \(G'\) that correspond to it, which is an issue when defining the initial and final independent sets.\(^7\) To handle this, we add \(k\) more vertices \(f^1, \ldots, f^k\) with edges \(f^i v^i\) for all \(v \in V\) and \(i \in [1, k]\). Furthermore, we add two vertices \(z_{\text{init}}\) and \(z_{\text{fin}}\), with edges \(f^i z_{\text{init}}\) for all \(i \in [1, k]\) and \(v^i z_{\text{fin}}\) for all \(v \in V \setminus \{z_{\text{init}}\}\). Let \(G''\) be the resulting graph.

We set \(I'_{\text{fin}} = f^1, \ldots, f^k\) and \(I'_{\text{init}} = \{(s_i)^i : i \in [1, k]\} \cup \{z_{\text{init}}\}\) for \(s_1, \ldots, s_k\) an arbitrary order on the \(k\) vertices in \(I_{\text{init}}\). We define \(f(A) = (G'', I'_{\text{init}}, I'_{\text{fin}}, k + 1)\).

We omit the details why this construction works, and only give an informal explanation. A TJ-reconfiguration sequence \(I_{\text{init}} = I_0, I_1, \ldots, I_k = I_{\text{fin}}\) in \(A\) can be converted to a TS-reconfiguration sequence \(I'_{\text{init}} = I_0, I_1', \ldots, I_k'\) by numbering the tokens in \(I_{\text{init}}\) the way we did for \(I'_{\text{init}}\) and ‘tracking’ their movements to the sequence, mimicking the movements within \(A\). Once we reach some set \(I_i'\) that ‘corresponds’ to \(I_i\), we can move the token from \(z_{\text{init}}\) to \(z_{\text{fin}}\) and then all the other tokens to \(f^i\) for all \(i \in [1, k]\) by \(k\) further moves. This is the only way to arrive at \(I'_{\text{fin}}\): \(G''\) has \(k + 1\) disjoint cliques \((V^1 \cup \{f^1\}, \ldots, V^k \cup \{f^k\}\) and \(z_{\text{init}}, z_{\text{fin}}\)) and there are \(k + 1\) tokens, so exactly one token must be in each clique at any moment. In particular, the tokens are forced to stay in their respective cliques. The token starting at \(z_{\text{init}}\) must move to \(z_{\text{fin}}\). As long as the token is on \(z_{\text{init}}\), the \(f^i\) vertices cannot receive a token. The token on \(z_{\text{init}}\) can only move to \(z_{\text{fin}}\) if the tokens in the other cliques correspond to the (original) final independent set \(I_{\text{fin}}\). Once \(z_{\text{fin}}\) has a token, the other tokens can move to \(f^i\) for all \(i \in [1, k]\). This implies that there is a sequence in \(A\) of length \(\ell\) if and only if there is one in \(f(A)\) of length \(\ell + k + 1\).

\(^7\) We could have solved this as well by considering \(k!\)-to-1 reductions instead. In fact, the ‘ordered TJ-reconfiguration graph’ of \(G\) is isomorphic to the ‘TS-reconfiguration graph’ of \(G''\).
Lemma 18. There exists a pl-reduction $f$ from TS-Independent Set Reconfiguration to Partitioned TS-Independent Set Reconfiguration, such that for any instance $A$ of TS-Independent Set Reconfiguration with $k$ tokens, $A$ admits a reconfiguration sequence of length $\ell$ if and only if $f(A)$ admits a reconfiguration sequence of length $\ell + k + 1$.

Proof. Let $A = (G, I_{\text{init}}, I_{\text{fin}}, k)$ be an instance of TS-Independent Set Reconfiguration with $G = (V, E)$. We create $k$ sets $P^1, \ldots, P^k$, where each $P^i$ is a copy of $V$. We write $v^i \in P^i$ for the $i$th copy of $v \in V$. Each $P^i$ forms a token set, meaning that each independent set must contain exactly one vertex from $P^i$. This chosen vertex in $P^i$ models the choice of the $i$th token in $A$.

We add the edges $v^i w^j$ for all $i, j \in [1, k]$ with $vw \in E$ or $v = w$. This defines a graph $G'$. The proof now continues as in the proof of Lemma 17; there is again a $k$!-to-one correspondence between independent sets $I'$ of $G'$ and independent sets $I$ of $G$ (for $I'$ of size $k$ in $G'$, we consider the set of $v \in V$ for which $v^i \in I'$ for some $i \in [1, k]$). We obtain $G''$ from $G'$ by adding new vertices $f^1, \ldots, f^k, z_{\text{init}}$ and $z_{\text{fin}}$ and the same edges as in the proof of Lemma 17 and add $f^i$ to the $i$th token set. Again, an extra token set with $\{z_{\text{init}}, z_{\text{fin}}\}$ is created. The remainder of the analysis is analogous.

Lemma 19. There exists a pl-reduction $f$ from Partitioned TS-Independent Set Reconfiguration to Partitioned TJ-Independent Set Reconfiguration, such that for any instance $A$ of Partitioned TS-Independent Set Reconfiguration, $A$ admits a reconfiguration sequence of length $\ell$ if and only if $f(A)$ admits a reconfiguration sequence of length $3\ell$.

Proof. Let $A = (G, I_{\text{init}}, I_{\text{fin}}, k)$ be an instance of Partitioned TS-Independent Set Reconfiguration with $G = (V, E)$ and $P_1, \ldots, P_k$ the tokens sets.

Let $i \in [1, k]$. We create two vertex sets $A_i$ and $B_i$ that contain a copy $v^a$ and $v^b$ respectively of each vertex $v \in P_i$. We add edges $v^a w^b$ for all $v, w \in P_i$, with $v \neq w$, as well as edges $v^a w^a$ for $vw \in E$. Finally, for each $vw \in E(G[P_i])$, we add a vertex $\delta_{vw}$ that we connect to $v^b$ and $w^b$, and we connect all $\delta_{vw}$ vertices to each other. Let $G'$ be the resulting graph. We model the $i$th token being on vertex $v$ in $A$ by a token on $v^a$.

In any independent set $I'$ of $G'$, either $v^a$ and $v^b$ are in $I'$ for some $v \in P_i$, or $v^a$ and $\delta_{vw}$ are in $I'$ for some $v \in P_i$ and $vw \in E(G[P_i])$. Moreover, $I'$ can contain at most one $\delta_{vw}$ vertex. To any independent set $I$ in $G$, we correspond the independent set $g(I)$ of size $2k$ in $G'$ given by $\{v^a, v^b : v \in I\}$. We create an instance $f(A) = (G', g(I_{\text{init}}), g(I_{\text{fin}}), 2k)$. The token sets are given by the partition $P'_1, \ldots, P'_{2k}$ with for $i \in [1, k]$, $P'_i = A_i$ and

$$P'_{k+i} = B_i \cup \{\delta_{vw} : vw \in E(G[P_i])\}.$$ 

A slide from $v$ to $w$ (say from $I_1$ to $I_2$) over an edge $vw \in E(G[P_i])$ corresponds to the sequence of jumps $v^b \rightarrow \delta_{vw}, v^a \rightarrow w^a, \delta_{vw} \rightarrow w^b$ (say from $g(I_1)$ to $g(I_2)$). For each reconfiguration sequence $I_0, \ldots, I_{\ell}$ in $A$ of length $\ell$, there is a reconfiguration sequence of length $3\ell$ in $f(A)$ of the form $g(I_0), I_{\text{init}}, I_0', g(I_1), I_{\text{init}}, \ldots, g(I_{\ell})$. Conversely, if there is no reconfiguration sequence between $I_{\text{init}}$ and $I_{\text{fin}}$ of length at least $\ell$, then any sequence in $f(A)$ from $g(I_{\text{init}})$ to $g(I_{\text{fin}})$ must have a subsequence of length at least $\ell + 1$ consisting of distinct independent sets $g(I_0), \ldots, g(I_{\ell})$; and between any two must be at least two more independent sets not of the form $g(I)$. Hence there is also no reconfiguration sequence between $g(I_{\text{init}})$ and $g(I_{\text{fin}})$ of length $3\ell$. We therefore conclude that there is a reconfiguration sequence of length $\ell$ between $I_{\text{init}}$ and $I_{\text{fin}}$ if and only if there is one of length $3\ell$ between $g(I_{\text{init}})$ and $g(I_{\text{fin}}).$
Lemma 20. There exists a pl-reduction \( f \) from Partitioned TJ-Independent Set Reconfiguration to TJ-Independent Set Reconfiguration, such that for any instance \( \mathcal{A} \) of Partitioned TJ-Independent Set Reconfiguration, \( \mathcal{A} \) admits a reconfiguration sequence of length \( \ell \) if and only if \( f(\mathcal{A}) \) admits a reconfiguration sequence of length \( 3\ell \).

Proof. Let \( \mathcal{A} = (G, l_{\text{init}}, l_{\text{fin}}, k) \) be an instance of Partitioned TJ-Independent Set Reconfiguration with \( G = (V, E) \) and \( P_1, \ldots, P_k \) the token sets.

The construction is similar to the one in the proof of Lemma 19. We first create token gadgets. Let \( i \in [1, k] \). We create two copies of each vertex \( v \in P_i \), called \( v^a \) and \( v^b \), and add the edges \( v^a w^a \), \( v^b w^b \) and \( v^a w^b \) for all vertices \( v \neq w \) in \( P_i \). We also add the edges \( v^a w^a \) if \( vw \in E \). Moreover, we add a vertex \( \delta_i \), which is connected to \( v^b \) for all \( v \in P_i \). This forms the \( i \)th token gadget. Finally, we connect \( \delta_i \) and \( \delta_j \) for all \( i, j \in [1, k] \). Let \( G' \) be the resulting graph.

We claim that any independent set \( I' \) of \( G' \) can contain at most two vertices of any token gadget. Let \( i \in [1, k] \). If \( I' \) contains \( \delta_j \), then it cannot contain anything from \( \{ v^b : v \in P_i \} \). Since \( I' \) can contain at most one vertex from \( \{ v^a : v \in P_i \} \) (which forms a clique), it intersects \( I' \) in at most two vertices. In fact \( I' \) can only contain two vertices from the \( i \)th token gadget if it contains \( v^a \) and \( v^b \), or \( v^a \) and \( \delta_i \) for some \( v \in P_i \). Since we will have \( 2k \) tokens, exactly two tokens must be in each of the token gadgets. This models a choice of \( v \in P_i \) for each \( i \in [1, k] \). By enforcing that at most one \( \delta_i \) can contain a token, we enforce that the vertex \( v^a \) can be changed for \( v \in P_i \) for only a single \( i \in [1, k] \) at a time.

The proof continues as in the proof of Lemma 19 each jump of the ith token from \( v \) to \( w \) in \( G \) is modelled by three jumps in \( G' \), namely \( v^a \) to \( \delta_i \), \( v^a \) to \( w^a \) and \( \delta_j \) to \( w^b \), and at least three jumps need to take place in order to move a token from \( v^a \) to \( w^a \) in \( G' \).

D.2 Equivalences for Dominating Set

Lemma 21. There exists a pl-reduction \( f \) from TJ-Dominating Set Reconfiguration to TS-Dominating Set Reconfiguration, such that for any instance \( \mathcal{A} \) of TJ-Dominating Set Reconfiguration with \( k \) tokens, \( \mathcal{A} \) admits a reconfiguration sequence of length \( \ell \) if and only if \( f(\mathcal{A}) \) admits a reconfiguration sequence of length \( \ell + k + 1 \).

Proof. Let \( \mathcal{A} = (G, D_{\text{init}}, D_{\text{fin}}, k) \) be an instance of TJ-Dominating Set Reconfiguration with \( G = (V, E) \) and \( k = |D_{\text{init}}| \) tokens. We create an instance \( f(\mathcal{A}) \) of TS-Dominating Set Reconfiguration with \( k + 1 \) tokens. For each token \( i \in [1, k] \) of \( \mathcal{A} \), we first create the following gadget that models on which vertex of \( G \) the token is. Let \( V' = \{ v^i : v \in V \} \) be a copy of \( V \) and let it induce an \( n \)-vertex clique. To certify that at least one token is in each \( V^i \), we add vertices \( \text{gar}_i \) and \( \text{gar}'_i \), both connected to all vertices in \( V^i \). If a token is placed on \( v^i \), this corresponds to placing the \( i \)th token on vertex \( v \).

We want to prohibit the tokens to be on copies of the same vertex \( v \in V \). To do this, we create a vertex \( x_{i,j}^v \) for all \( i, j \in [1, k] \) \( i \neq j \) and all \( v \in V \), which we connect to \( w^i \) and \( w^j \) for all \( w \in V \setminus \{ v \} \). Assuming that exactly one token is in each \( V^i \), this implies that not both \( v^i \) and \( v^j \) can be in the dominating set, because then \( x_{i,j}^v \) is not dominated.

The chosen tokens should be a dominating set. To accomplish this, we add a vertex \( v' \) for all \( v \in V \), with edges \( v' w^i \) for all \( i \in [k] \) and all \( w^i \in V^i \) such that \( vw \in E \) or \( v = w \). This results in a graph \( G' \).

There is still the issue for any dominating set in \( G, k! \) different dominating sets in \( G' \) correspond to it, which is an issue when defining the initial and final dominating sets. To solve this, we add \( k + 4 \) more vertices \( f^1, \ldots, f^k, z_{\text{init}}, z_{\text{fin}}, z_{\text{gar}} \) and \( z'_{\text{gar}} \). We add edges \( f^i \text{gar}_i \) and \( f' \text{gar}'_i \) for all \( v \in D_{\text{fin}} \) for all \( i \in [1, k] \). This is such that a slide from \( v^i \) to \( f^i \) can...
only happen if \( v \in D_{\text{fin}} \). Furthermore we connect \( z_{\text{gar}} \) and \( z'_{\text{gar}} \) only to \( z_{\text{init}} \) and \( z_{\text{fin}} \) to ensure one token to always be on \( z_{\text{init}} \) or \( z_{\text{fin}} \). We add edges \( f'_i z_{\text{init}} \) for all \( i \in [1, k] \). Finally, we connect \( z_{\text{fin}} \) to \( z_{\text{init}} \) and to all \( v', v^1, \ldots, v^k \) for all \( v \in V \). Call the resulting graph \( G'' \).

Note that because of the ‘guardian’ vertices, the pigeonhole principle implies that exactly one token is in the set \( V' \cup \{ f^i \} \) for all \( i \in [1, k] \) and exactly one token is on either \( z_{\text{init}} \) or \( z_{\text{fin}} \).

Let \( D_{\text{init}} = \{ v_1, \ldots, v_k \} \) be the initial dominating set of \( A \). We set \( D'_{\text{init}} = \{(v_i)^j : i \in [1, k]\} \cup \{z_{\text{init}}\} \) and \( D'_{\text{fin}} = \{f^1, \ldots, f^k, z_{\text{fin}}\} \).

We omit the details why this construction works, and only give an informal explanation.

A T3-reconfigurations sequence \( D_{\text{init}} = D_0, D_1, \ldots, D_t = D_{\text{fin}} \) in \( A \) can be converted to a TS reconfiguration sequence \( D'_{\text{init}} = D'_0, D'_1, \ldots, D'_t \) by numbering the tokens in \( D_{\text{init}} \) the way we did for \( D'_{\text{init}} \) and ‘tracking’ their movements to the sequence, mimicking the movements within \( G'' \). Once we reach some set \( D'_i \) that ‘corresponds’ to \( D_{\text{fin}} \), we can move the tokens from \( D'_i \) to \( D'_{\text{fin}} \) by \( k + 1 \) further moves: first move \( z_{\text{init}} \) to \( z_{\text{fin}} \) and then the other tokens to \( f^1, \ldots, f^k \). Note that the first move can only happen if all \( f^i \) are dominated, meaning that \( D'_i \) must indeed correspond to \( D_{\text{fin}} \).

This implies that there is a sequence in \( A \) of length \( \ell \) if and only if there is one in \( f(A) \) of length \( \ell + k + 1 \).}

Lemma 22. There exists a pl-reduction \( f \) from TS-DOMINATING SET RECONFIGURATION to PARTITIONED TS-DOMINATING SET RECONFIGURATION, such that for any instance \( A \) of TS-DOMINATING SET RECONFIGURATION with \( k \) tokens, \( A \) admits a reconfiguration sequence of length \( \ell \) if and only if \( f(A) \) admits a reconfiguration sequence of length \( \ell + k + 1 \).

Proof. Let \( A = (G, D_{\text{init}}, D_{\text{fin}}, k) \) be an instance of TS-DOMINATING SET RECONFIGURATION with \( G = (V, E) \). We create the following instance of PARTITIONED TS-DOMINATING SET RECONFIGURATION with \( k' = k + 2 \) tokens. Create \( k \) copies of \( G \), denoted by \( G^1, \ldots, G^k \). Each of these copies is a token set, meaning that each dominating set must contain exactly one of the vertices of \( G^i \). The chosen vertex in \( G^i \) models the choice of the \( i \)th token in \( A \).

We want all tokens to be copies on different vertices. To accomplish this, we create a vertex \( x_{v}^{i,j} \) for all \( i, j \in [1, k], (i \neq j) \), and all \( v \in V \) with edges \( x_{v}^{i,j} w^i \) and \( x_{v}^{i,j} w^j \) for all \( w \in V \setminus \{v\} \). This ensures that no two tokens are on the same copy of a vertex: if both \( v^i \) and \( v^j \) are in the dominating set, then \( x_{v}^{i,j} \) is not dominated.

The chosen vertices should be a dominating set. To check this, we add a vertex \( v' \) for all \( v \in V \), with edges \( v' w^i \) for all \( i \in [1, k] \) and all \( w \in V \) such that \( v w = v \) or \( v = w \). Finally, we add three vertices \( y_{\text{dom}} \), \( y_{\text{gar}} \), \( y'_{\text{gar}} \) and add edges \( y_{\text{dom}} y_{\text{gar}} \), \( y_{\text{dom}} y'_{\text{gar}} \) and \( y_{\text{dom}} v_i \) for all \( i \in [1, k], v \in V \). We then create a token set \( \{v'\}_{v \in V} \cup \{y_{\text{dom}}, y_{\text{gar}}, y'_{\text{gar}}\} \). Now \( y_{\text{dom}} \) is in any dominating set because of \( y_{\text{gar}} \) and \( y'_{\text{gar}} \). Also, \( y_{\text{dom}} \) dominates all vertices in \( G^1, \ldots, G^k \).

We choose to add \( \{v'\}_{v \in V} \) to this token set, because the token sets should form a partition of the vertices in the instance \( f(A) \). We call this graph \( G' \).

We note that the \( i \)th token in \( G \) can slide from \( v \) to \( w \) in \( A \) if and only if token \( i \) in \( f(A) \) can slide from \( v_i \) to \( w_i \). The proof now continues as in the proof of Lemma [21] there is again a \( k! \)-to-one correspondence between dominating sets \( D' \) of \( G' \) and dominating sets \( D \) of \( G \) (for \( D' \) of size \( k + 1 \) in \( G' \), we consider the set of \( v \in V \) for which \( v' \in D' \) for some \( i \in [1, k] \)). We obtain \( G'' \) from \( G' \) by adding new vertices \( f^1, \ldots, f^k, z_{\text{init}}, z_{\text{fin}}, z_{\text{gar}}, z'_{\text{gar}} \) and adding \( f^i \) to the \( i \)th token set. The remainder of the analysis is analogous.}

Lemma 23. There exists a pl-reduction \( f \) from PARTITIONED TS-DOMINATING SET RECONFIGURATION to PARTITIONED TJ-DOMINATING SET RECONFIGURATION, such that for any instance \( A \) of PARTITIONED TS-DOMINATING SET RECONFIGURATION, \( A \) admits a
reconfiguration sequence of length $\ell$ if and only if $f(A)$ admits a reconfiguration sequence of length $3\ell + 1$.

**Proof.** Let $A = (G, D_{\text{init}}, D_{\text{fin}}, k)$ be an instance of Partitioned TS-Dominating Set Reconfiguration with $G = (V, E)$ and $P_1, \ldots, P_k$ the token sets. We create $k$ token gadgets in $f(A)$, each modelling the choice of one token, as follows. Let $i \in [1, k]$. We create vertices $v^a$, $v^b$, $v^c$ and $v^d$ for all $v \in P_i$. We create token sets $\{v^a\}_{v \in P_i}$ and $\{v^c\}_{v \in P_i}$, meaning exactly one vertex of those sets should be in any dominating set. The following edges are created:

\[
\begin{align*}
v^a v^b & \quad \forall v \in V, & v^c v^d & \quad \forall v \in V, \\
v^a w d & \quad \forall v, w \in V, v \neq w, & v^cw b & \quad \forall v, w \in V, v \neq w, \\
v^a w a & \quad \forall v, w \in V, v \neq w, & v^cw a & \quad \forall v, w \in V, v \neq w.
\end{align*}
\]

The edges ensure that the two tokens of the token sets $\{v^a\}_{v \in P_i}$ and $\{v^c\}_{v \in P_i}$ can only move away from exactly one vertex. We then have the token set $v$, connect all the vertices within this token set.

To verify that our choice of tokens induces a dominating set, we add another copy $v'$ for all $v \in V$, and connect $v'$ with $w^a$ for all $w \in V$ such that $vw \in E$ or $v = w$. Because all vertices should be part of a token set, we create one additional vertex, $z_{\text{dom}}$, connected to no other vertex. We then have the token set $\{v'\}_v \cup \{v^b\}_v \cup \{v^d\}_v \cup \{z_{\text{dom}}\}$, where the token should always be on $z_{\text{dom}}$. Let $G'$ be the resulting graph.

Let the initial and final dominating sets for $G'$ be

\[
\begin{align*}
D'_{\text{init}} &= \{v^a, v^c\}_v \cup \{z_{\text{dom}}\} \cup \{\delta_b\} \quad \text{and} \\
D'_{\text{fin}} &= \{v^a, v^c\}_v \cup \{z_{\text{dom}}\} \cup \{\delta_b\}.
\end{align*}
\]

We create an instance $f(A) = (G', D'_{\text{init}}, D'_{\text{fin}}, 2k + 2)$ with the token sets as described above. For any reconfiguration sequence $D_{\text{init}} = D_0, D_1, \ldots, D_\ell = D_{\text{fin}}$ in $A$ of length $\ell$, there is a reconfiguration sequence of length $3\ell + 1$ in $f(A)$ of the form

\[
D_{\text{init}} = g_1(D_0), g_2(D_0), g_3(D_0), \ldots, g_\ell(D_\ell) = D'_{\text{fin}},
\]

where

\[
\begin{align*}
g_1(D) &= \{v^a, v^c\}_v \cup \{z_{\text{dom}}\} \cup \{\delta_{x'y'}\}, & \text{for } x'y' \text{ last slide-edge}, \\
g_2(D) &= \{v^a, v^c\}_v \cup \{z_{\text{dom}}\} \cup \{\delta_{xy}\}, & \text{for } xy \text{ next slide-edge}, \\
g_3(D) &= \{v^a, v^c\}_v \setminus \{x^a\} \cup \{y^a\} \cup \{z_{\text{dom}}\} \cup \{\delta_{xy}\}, & \text{for } xy \text{ next slide-edge}.
\end{align*}
\]

(We let the last slide-edge of $D_{\text{init}}$ be the edge corresponding to the edge token in $D'_{\text{init}}$, and the next slide-edge of $D_{\text{fin}}$ be the edge corresponding to the edge token in $D'_{\text{fin}}$.)

We say the $i$th token is ‘sliding’ in $f(A)$ if there are tokens on $v^a$ and $v^c$ for $v \neq w$ elements of $P_i$. Note that at most one token can be ‘sliding’ at the same time in $f(A)$: the edge token can only move away from $\delta_{vy}$ if there are two tokens on $v^a$ and $v^c$, or two tokens
on $w^a$ and $w^c$. Therefore, any minimal length reconfiguration sequence in $f(A)$ is of some length $3\ell + 1$ (namely three steps per slide and one additional jump to get to $D_{6n}^e$). Any such reconfiguration sequence of $f(A)$ from $g_1(D_{5a})$ to $g_1(D_{6b})$ must have a subsequence of length $\ell$ of distinct dominating sets $g_1(D_0), \ldots, g_1(D_\ell)$ (where we take every third dominating set in the sequence). This gives a sequence of length $\ell$ in $A$.

Lemma 24. There exists a pl-reduction $f$ from Partitioned TJ-Dominating Set Reconfiguration to TJ-Dominating Set Reconfiguration, such that for any instance $A$ of Partitioned TJ-Dominating Set Reconfiguration, $A$ admits a reconfiguration sequence of length $\ell$ if and only if $f(A)$ admits a reconfiguration sequence of length $\ell$.

Proof. We keep the same number of tokens $k$. Let $P_1, \ldots, P_k$ be the token sets of the Partitioned TJ-Dominating Set Reconfiguration instance. For $i \in [1,k]$, we add vertices $gar_i$ and $gar'_i$, both connected to all vertices in $P_i$. This ensures that there is exactly one token in each of the sets $P_i$, modeling the token sets of $A$. As a consequence, only jumps within $P_i$ are allowed. Therefore, any jump in $A$ can be modelled by a jump in $f(A)$ and vice versa.

D.3 Proof of Theorem 6

All variants of Independent Set Reconfiguration and Dominating Set Reconfiguration are equivalent under pl-reductions by Lemmas D.1–D.8.

To see that these results also hold for the timed reconfiguration variants, we take a closer look at the aforementioned reductions. For each reduction $f$ in one of the Lemmas D.1–D.8, we gave a function $h(k,\ell)$ (linear in its two parameters) such that instance $A$ with $k$ tokens has a reconfiguration sequence of length $\ell$ if and only if $f(A)$ has a reconfiguration sequence of length $h(k,\ell)$. Therefore the bound on the sequence length $\ell$ given in instances $A$ of Timed Independent Set Reconfiguration, Binary Independent Set Reconfiguration or Timed Independent Set Reconfiguration (when moreover parameterized by the length of the sequence), only grow polynomially in $\ell$ and $k$ when reducing to an instance $f(A)$ of the same problem (but a different sliding/jumping variant). The same arguments hold for the dominating set variants. This concludes the proof of Theorem 6.

We note pl-reductions are a special case of fpt-reductions, as a space limit of $O(g(k) + \log n)$ implies a runtime bound of $O(2^{g(k)} \cdot n^c)$ for some constant $c$.
