SOME A PRIORI ESTIMATES FOR THE HOMOGENEOUS LANDAU EQUATION
WITH SOFT POTENTIALS

R. ALEXANDRE, J. LIAO, AND C. LIN

ABSTRACT. This paper deals with the derivation of some a priori estimates for the homogeneous Landau
equation with soft potentials. Using the coercivity of the Landau operator for soft potentials, we prove
a global estimate of weak solutions in $L^2$ space without any smallness assumption on the initial data
for $-2 < \gamma < 0$. For the stronger case $-3 \leq \gamma \leq -2$, which covers in particular the Coulomb case, we
get such a global estimate, but in some weighted $L^2$ space and under a smallness assumption on initial
data.

1. INTRODUCTION

The classical homogeneous Landau equation (also called Fokker-Planck-Landau equation) is a common
model in kinetic theory, see Chapman-Cowling [8] and Lifschitz-Pitaevskii [17]. This equation is obtained as a continuous approximation of the Boltzmann equation when grazing collisions prevail,
see for instance [1, 2, 9, 15, 23] for a detailed study of the limiting process, and references therein
on this subject. It describes the evolution of the (homogeneous) density function $f(t,v)$ of particles having the velocity $v \in \mathbb{R}^3$ at time $t > 0$:

\begin{equation}
\partial_t f = \partial_v \left\{ \int_{v_0} a_{ij}(f_s \partial_v f - f \partial_v f_s) \right\},
\end{equation}  

where

\begin{equation}
a_{ij}(z) = |z|^{\gamma+2} \Pi_{ij}(z), \quad \Pi_{ij}(z) = \delta_{ij} - \frac{z_i z_j}{|z|^2}, \quad z \neq 0.
\end{equation}

The properties of the Landau equation depend heavily on $\gamma$. It is customary to speak of hard potentials for $\gamma > 0$, and soft potentials for $\gamma \in (-3,0)$. The special cases, $\gamma = 0$ and $\gamma = -3$, are
called the Maxwellian and Coulomb potentials, respectively. Note the fact that the more $\gamma$ is negative, the
more the Landau equation is physically interesting, see Villani [25] for a detailed survey about
such considerations. We refer to [11, 12, 23, 25] for more details on this equation and its physical meanings.

For a given nonnegative initial data \( f_0 \), we shall use the notations

\[
(1.3) \quad m_0 = \int_{\mathbb{R}^3} f_0(v)dv, \quad e_0 = \frac{1}{2} \int_{\mathbb{R}^3} f_0(v) |v|^2 dv, \quad H_0 = \int_{\mathbb{R}^3} f_0(v) \log f_0(v)dv,
\]

for the initial mass, energy and entropy. It is classical that if \( f_0 \geq 0 \) and \( m_0, e_0, H_0 \) are finite, then \( f_0 \) belongs to

\[
L \log L(\mathbb{R}^3) = \{ f \in L^1(\mathbb{R}^3) : \int_{\mathbb{R}^3} |f(v)| \log(|f(v)|)dv < \infty \}.
\]

The solution of the Landau equation satisfies, at least formally, the conservation of mass, momentum and energy, that is, for any \( t > 0 \),

\[
\int_{\mathbb{R}^3} f(t,v)\varphi(v)dv = \int_{\mathbb{R}^3} f_0(v)\varphi(v)dv, \quad \varphi(v) = 1, \; v, \; |v|^2/2.
\]

We also define

\[
m = \int_{\mathbb{R}^3} f(t,v)dv = m_0, \quad e = \int_{\mathbb{R}^3} f(t,v)\frac{|v|^2}{2}dv = e_0.
\]

Another fundamental a priori estimate is the decay of entropy, that is, the solution satisfies, at least formally, for any \( t > 0 \),

\[
\int_{\mathbb{R}^3} f(t,v) \log f(t,v)dv \leq \int_{\mathbb{R}^3} f_0(v) \log f_0(v)dv.
\]

For \( s \geq 0 \), we introduce classical weighted spaces as follows

\[
\|f\|_{L^1_s(\mathbb{R}^3)} = \int_{\mathbb{R}^3} |f(v)| < v >^s dv = M_s(f),
\]

\[
\|f\|_{L^2_s(\mathbb{R}^3)}^2 = \int_{\mathbb{R}^3} |f(v)|^2 < v >^{2s} dv,
\]

where \( < v >= (1 + |v|^2)^{1/2} \). And we set

\[
b_i = \partial_i a_i(z), \quad c(z) = \partial_i a_{ij}(z),
\]

\[
\bar{a}_{ij} = a_{ij} * f, \quad \bar{b}_i = b_i * f, \quad \bar{c} = c * f.
\]

If \( \gamma > -3 \), we have

\[
a_{ij} = \Pi_{ij}(z)|z|^\gamma z_i z_j, \quad b_i = -2|z|^{\gamma+2} \frac{z_i}{|z|^2}, \quad c = -2(\gamma + 3)|z|^\gamma,
\]

and if \( \gamma = -3 \), the first two formulas remain true while the third one is replaced by

\[
c = -8\pi \delta_0.
\]

The theory of the homogeneous Landau equation for hard potentials is studied in great details by Desvillettes-Villani [11, 12], while the particular case of Maxwellian molecules \( \gamma = 0 \) can be found in Villani [24].

However, there are only scattered results concerning the soft potentials. We mention the compactness properties in Lions [18] and the existence of weak solutions in the inhomogeneous context by means of renormalization tools in Villani [21] for very soft potentials, the existence of H-solution under some assumptions on initial conditions considered in Villani [23]. By using a probabilistic approach, Guerin [16] studied the existence of a measure solution for \( \gamma \in (-1,0) \). Still by probabilistic approach, Fournier-Guerin [14] studied the uniqueness and local existence of such weak solutions for soft potentials. For the Coulomb potential case \( \gamma = -3 \), Arsen’ev-Peskov [3] studied the local
existence of weak solutions and Fournier [13] considered the local well-posedness result for such solutions. All these results give a priori estimates of solutions in some $L^p$ spaces, globally if $-2 < \gamma < 0$ and locally if $-3 \leq \gamma \leq -2$.

This paper is devoted to some further a priori energy estimates by using the coercivity of the Landau operator for soft potentials, given in Desvillettes-Villani [11], which is stated and proved therein for $\gamma > -2$ but remains true for $\gamma \geq -3$ (at least). Our main result is the following, where here and below we use $C$ or $C_i$ to denote a generic constant.

**Theorem 1.1.** Consider the Cauchy problem for the classical homogenous Landau equation (1.1)-(1.2) with initial data $f_0 \in L^1_2(\mathbb{R}^3) \cap L \log L(\mathbb{R}^3)$. Let the initial mass $m_0$, energy $e_0$ and entropy $H_0$ defined in (1.3) be finite. Then we have

1. Assume that $-2 \leq \gamma < 0$ and $f_0 \in L^2(\mathbb{R}^3)$. Then we have the following global in time a priori estimate on a weak solution in $L^2(\mathbb{R}^3)$

$$\|f(t)\|_{L^2(\mathbb{R}^3)}^2 \leq Ce^{Ct}(\|f_0\|_{L^2(\mathbb{R}^3)}^2 + C_1 t),$$

where the constants $C_1$ and $C_2$ depend on $\gamma$, $m_0$, $e_0$ and $H_0$.

2. Assume that $-3 \leq \gamma < -2$ and that $f_0 \in L^p_\infty(\mathbb{R}^3)$ for some $\alpha \geq -1 - 3\gamma/2$. Assume moreover that $\|f_0\|_{L^p_\infty(\mathbb{R}^3)}$ is suitably small. Then there exists a constant $\tilde{C}$ depending only on the entropy estimates of $f_0$ and on $\|f_0\|_{L^2_\infty(\mathbb{R}^3)}$ such that one has a global in time a priori estimate on a weak solution

$$f \in L^\infty([0, \infty); L^p_\infty(\mathbb{R}^3)) \quad \text{and} \quad \|f(t, \cdot)\|_{L^p_\infty(\mathbb{R}^3)} \leq \tilde{C}.$$

3. Under assumptions stated in 1. or 2. above, one has

$$f \in L^2(0, T; H^1_\alpha(\mathbb{R}^3))$$

for any fixed $T > 0$,

where $H_\alpha$ denotes the corresponding weighted Sobolev space.

We note that from these a priori energy estimates in weighted $L^2$ spaces and similar ones for higher derivatives, eventually with different weight functions which can be obtained following the general scheme displayed below, one could get the complete existence result by using the arguments of Desvillettes-Villani [11] and Arsen’ev-Peskov [3]. In particular, one could eventually have an immediate regularization property of solutions.

Moreover, we remark that uniqueness and convergence to equilibrium results of these weak solutions can be derived based on the works of Fournier [13] and Fournier-Guerin [14]. Note also that we decided to work in $L^2$ type spaces, but our proofs can also be adapted to more general weighted $L^p$ spaces with $1 < p < +\infty$, at the expense of changing one crucial argument used in the proofs, namely Pitt’s inequality, see Beckner [4, 5, 6] for example. Finally, a comparison with the recent result of Fournier-Guerin [14] shows that we slightly improve their results even in the case $\gamma > -2$ but close to $\gamma = -2$, and of course in the case $-3 \leq \gamma \leq -2$, though we need a smallness assumption.

The proof of our main result above rests mainly on Pitt’s inequality [4, 5, 6]. However, it is possible to avoid this inequality at least in the case of not too soft potentials $\gamma \in (-2, 0)$, by using standard Nash Gagliardo Nirenberg inequalities [19] for example, and assuming enough control of moments in $L^1$, as follows from Villani [23]. For example, one can show that

**Proposition 1.2.** Under the same hypothesis as in Theorem 1.1, assume moreover that $\gamma \in (-2, 0)$, that $M_\alpha(t)$ is bounded by $c_\mu(1 + t)$, where $\mu = \frac{4\gamma(3-\gamma)}{3(2+\gamma)}$. Then it follows that

$$\|f(t)\|_{L^2(\mathbb{R}^3)}^2 \leq C(1 + t)^2.$$

Comparing with Theorem 1.1, we improve on the temporal growth of this $L^2$ norm. But we do ask for many more moments: in particular, note that for $\gamma$ very close to $-2$, then we ask for almost all
moments to be controlled. This point might be linked with working with $L^2$ type estimations, see last Section for further comments.

The organization of the paper is as follows. Firstly, a proposition of coercivity for soft potentials is proved in Section 2, following the arguments of Desvillettes-Villani [11], for $\gamma \geq -3$. This section is merely for the convenience of the reader since the proof follows by carefully looking to the proof in [11].

Then in Section 3, the a priori energy estimates are carried out for the case $\gamma \in (-2, 0)$ to get the global estimate of weak solutions, giving the first part of Theorem 1.1. In Section 4, we carry out the weighted energy estimates for the case $-3 < \gamma \leq -2$ to get the global estimates of weak solutions in weighted $L^2$ spaces, upon a smallness assumption on the initial data. This gives the second part of Theorem 1.1, completed by Section 5, for the special case $\gamma = -3$.

In Section 6, again the same process is shown to yield local in time estimate for the case $\gamma \in (-3, -2)$, unless we can get better moment estimates in $L^1$ (that is, if the moment is uniformly bounded w.r.t. time). But up to now, we have only a upper bound with a linear time growth according to Villani [22].

Finally, Section 7 is devoted to the proof of Proposition 1.2.

2. Coercivity

This section is devoted to the proof of coercivity for soft potentials, which is an extension of hard potential case in Desvillettes-Villani [11]. In fact as mentioned to us by Desvillettes, the proof stated therein works for $\gamma > -2$ but we show that it still holds true for $\gamma \geq -3$.

Proposition 2.1. (Coercivity) Let $\gamma \in [-3, 0)$. Let $f \in L^1 \cap L \log L(\mathbb{R}^3)$ with $m(f) = m_0$, $e(f) \leq e_0$, $H(f) \leq H_0$. Then there exist a constant $C_{\text{coer}}$, explicitly computable and depending on $\gamma$, $m_0$, $e_0$ and $H_0$, such that

$$\forall \xi \in \mathbb{R}^3, \quad \bar{a}_{ij} \xi_i \xi_j \geq C_{\text{coer}} < v >^{\gamma} |\xi|^2.$$  

To prove the coercivity proposition, we use the same notations as in [11], and recall the following lemma from [11]:

Lemma 2.2. Let $f \geq 0$ be a function of $L^1(\mathbb{R}^3)$ such that $m(f) = m_0$, $e(f) \leq e_0$, $H(f) \leq H_0$. Then, for all $\epsilon > 0$, there exists $\eta(\epsilon) > 0$, depending only on $m_0$, $e_0$, $H_0$ such that for any measurable set $A \subset \mathbb{R}^3$,

$$|A| \leq \eta(\epsilon) \Rightarrow \int_A f \leq \epsilon,$$

where $|A|$ denotes the Lebesgue measure of $A$.

Proof of Lemma 2.2: the arguments are taken from the nonhomogeneous case dealt with by Desvillettes [10]. But we slightly modify some of his steps, since we display an explicit expression of $\eta(\epsilon)$ which could be required elsewhere (and which of course is not unique as regards of the proof below).

We note firstly that

$$\int f |\log f| - \int f \log f = 2 \int_{f \leq 1} -f \log f$$

$$= 2 \int_{e^{-1/w_0^2} \leq f \leq 1} -f \log f + 2 \int_{f \leq e^{-1/w_0^2}} -f \log f$$

$$\leq 2m + 2e + 3(2\pi)^3 \exp(1).$$

Using the decrease of entropy, and the conservation of mass and energy, it follows that
\[
\int f|\log f| \leq H_0 + 2m_0 + 2e_0 + 3(2\pi)^3 \exp(1) \equiv \tilde{H}_0.
\]

Now let a fix an arbitrary set \( A \). One has, for all \( \delta \geq 1 \)

\[
\int_A f = \int_{A, f \leq \delta} f + \int_{A, f \geq \delta} f \leq \delta |A| + (\log \delta)^{-1} \tilde{H}_0.
\]

Assume that \( |A| \leq \frac{\tilde{H}_0}{\delta \log \delta} \). Then it follows that

\[
\int_A f \leq 2\tilde{H}_0 \frac{1}{\log \delta}.
\]

We want this to be less than a fixed \( \varepsilon > 0 \). It is enough to take the value of \( \delta \) as \( \delta = e^{2\tilde{H}_0 \varepsilon^{-1}} \). In conclusion, we have shown that setting

\[
\eta(\varepsilon) = \frac{\varepsilon}{2} e^{-2\tilde{H}_0 \varepsilon^{-1}},
\]

then it follows that

\[
\int_A f \leq \varepsilon
\]

for any measurable set \( A \) such that \( |A| \leq \eta(\varepsilon) \), ending the proof.

**Proof of Proposition 2.1:** Let \( \xi \in \mathbb{R}^3, |\xi| = 1, 0 < \theta < \frac{\pi}{2} \). And set

\[
D_{\theta, \xi}(v) = \left\{ v_* \in \mathbb{R}^3 : \left\| \frac{v - v_*}{|v - v_*|} : \xi \right\| \geq \cos \theta \right\},
\]

which is the cone centered at \( v \), of axis directed by \( \xi \) and of angle \( \theta \) (see the figure in [11]).

For all \( v_* \in \mathbb{R}^3 \setminus D_{\theta, \xi}(v) \), we have

\[
a_{ij}(v - v_*)\xi_i \xi_j = |v - v_*|^{2} \left\{ a_{ij} \right\} \left( \frac{v - v_*}{|v - v_*|^2} \right) \xi_i \xi_j
\]

\[
= |v - v_*|^{2} \left( 1 - \frac{v - v_*}{|v - v_*|^2} \right) \xi_i^2 \geq |v - v_*|^{2} \sin^2 \theta.
\]

Then for all \( v \in \mathbb{R}^3, \theta \in (0, \frac{\pi}{2}), R_* > 0 \), we get

\[
\tilde{a}_{ij}(v)\xi_i \xi_j \geq \int_{\mathbb{R}^3 \setminus D_{\theta, \xi}(v)} dv_v f_* \left( 1_{|v_*| \leq R_*} a_{ij}(v - v_*) \xi_i \xi_j \right)
\]

\[
\geq \int_{\mathbb{R}^3 \setminus D_{\theta, \xi}(v)} dv_v f_* \left( 1_{|v_*| \leq R_*} |v - v_*|^{2} f_* \sin^2 \theta \right).
\]

We first take care of large \( |v_*| \). Let \( R_* = 2(e_0/m_0)^{1/2} \) and \( B_* \) be the ball with center 0 and radius \( R_* \). Then

\[
\int_{B_*} dv_v f_* \geq m_0 \left( 1 - \frac{2e_0}{m_0 R_*^2} \right) \geq \frac{m_0}{2},
\]

and we also note that

\[
|B_* \cap D_{\theta, \xi}(v)| \leq 2\pi R_* (|v| + R_*)^2 \tan^2 \theta.
\]

We consider two cases:

**Case 1:** \(|v| \geq 2R_* \). Note that
\[ \forall v, v_* \in \mathbb{R}^3, |v| \geq 2R_*, |v_*| \leq R_* : \quad \frac{1}{2} |v| \leq |v - v_*| \leq \frac{3}{2} |v|, \]

from (2.2), we have

\[ (2.5) \quad a_{ij}(v)\xi_i \xi_j \geq \begin{cases} \left(\frac{1}{2}|v|^2\right)^{\gamma+2} \sin^2 \theta \int_{B_i \setminus D_{\kappa}(v)} dv_* f_* & \text{for } \gamma \in [-2, 0), \\ \left(\frac{3}{2}|v|^2\right)^{\gamma+2} \sin^2 \theta \int_{B_i \setminus D_{\kappa}(v)} dv_* f_* & \text{for } \gamma \in [-3, -2). \end{cases} \]

Now we choose \( \theta > 0 \) such that

\[ \tan^2 \theta = \min\left\{ \frac{2\eta(m_0)}{9\pi R_* |v|^2}, 1 \right\}, \]

so according to (2.4), we have

\[ |B_* \cap D_{\theta}(v)| \leq 2\pi R_* \left(\frac{3}{2} |v|^2\right)^{\tan^2 \theta} \leq \eta\left(\frac{m_0}{4}\right) \]

thus \( \int_{B_* \cap D_{\kappa}(v)} dv_* f_* \leq \frac{m_0}{4} \)

and then from (2.3) and (2.5) we have

\[ a_{ij}(v)\xi_i \xi_j \geq \begin{cases} \left(\frac{1}{2}|v|^2\right)^{\gamma+2} \sin^2 \theta \min\left\{ \frac{2\eta(m_0)}{9\pi R_* |v|^2}, 1 \right\} \left(\frac{2}{3} |v|^2\right)^{\gamma} \min\left\{ \frac{2\eta(m_0)}{9\pi R_* |v|^2}, 4R_*^2 \right\} & \text{for } \gamma \in [-2, 0), \\ \left(\frac{3}{2}|v|^2\right)^{\gamma+2} \sin^2 \theta \min\left\{ \frac{2\eta(m_0)}{9\pi R_* |v|^2}, 1 \right\} \left(\frac{2}{3} |v|^2\right)^{\gamma} \min\left\{ \frac{2\eta(m_0)}{9\pi R_* |v|^2}, 4R_*^2 \right\} & \text{for } \gamma \in [-3, -2), \end{cases} \]

which is also

\[ (2.6) \quad a_{ij}(v)\xi_i \xi_j \geq \eta|v|^\gamma > c < v >^\gamma \quad \text{for } \gamma \in [-3, 0), |v| \geq 2R_* \]

where \( c \) is a constant depending on \( \gamma, m_0, \epsilon_0 \) and \( H_0 \).

**Case 2:** \( |v| \leq 2R_* \). Note that when \( |v_*| \leq R_* \), we have \( |v - v_*| \leq 3R_* \) thus

\[ \int_{B_* \setminus D_{\kappa}(v)} dv_* f_* |v - v_*|^{\gamma+2} \geq \int_{B_* \setminus D_{\kappa}(v)} dv_* f_* |v - v_*|^{\gamma+3}/(3R_*) \]

\[ \geq \left[ \frac{2\eta(m_0)}{9\pi R_* |v|^2} \right]^{\gamma+3/3} \int_{B_* \setminus D_{\kappa}(v)} dv_* f_* 1_{|v - v_*| \geq \left[ \frac{1}{4} \eta\left(\frac{m_0}{8}\right) \right]^{1/3}}. \]

Note that

\[ \int_{B_* \setminus D_{\kappa}(v)} dv_* f_* 1_{|v - v_*| \geq \left[ \frac{1}{4} \eta\left(\frac{m_0}{8}\right) \right]^{1/3}} = \int_{B_* \setminus D_{\kappa}(v)} dv_* f_* - \int_{B_* \setminus D_{\kappa}(v)} dv_* f_* 1_{|v - v_*| \leq \left[ \frac{1}{4} \eta\left(\frac{m_0}{8}\right) \right]^{1/3}} \]

\[ \geq \int_{B_*} dv_* f_* - \int_{B_* \cap D_{\kappa}(v)} dv_* f_* - \frac{m_0}{8}, \]

and we know the first term is greater than \( m_0/2 \) from (2.3) . For the second term to be less than \( m_0/8 \), we expect

\[ |B_* \cap D_{\theta}(v)| \leq 2\pi R_* (3R_*^2)^{\tan^2 \theta} \leq \eta\left(\frac{m_0}{8}\right), \]

which requires

\[ \tan^2 \theta = \min\left\{ \frac{\eta\left(\frac{m_0}{8}\right)}{18\pi R_*^3}, 1 \right\}, \]
thus from (2.2) we have
\begin{equation}
\bar{a}_{ij}(v)\xi_i\xi_j \geq \left[ \frac{3}{32}\eta(\frac{m_0}{\pi}) \frac{m_0}{3R_*} \sin^2 \theta \right] \min \left[ \frac{1}{2 \pi R_*}, 1 \right], \text{for } |v| \leq 2R_*.
\end{equation}
Estimates (2.6) and (2.7) together ensure the validity of (2.1).
\[ \square \]

**Remark 2.3.** From the proof, we can see that actually the coercivity proposition holds for all \( \gamma < 0 \).

3. The case \( \gamma \geq -2 \): energy estimates

We multiply the equation (1.1) by \( f \) and integrate to get
\begin{equation}
\frac{d}{dt} \frac{1}{2} \| f \|_{L^2}^2 + \int \int a_{ij}(v - v_*) f_i \partial_{v_i} f \partial_{v_j} f = \frac{1}{2} \int \int a_{ij}(v - v_*) \partial_{v_i} f_\ast \partial_{v_j} f_\ast.
\end{equation}

The second term on the l.h.s. can be bounded below by using the coercivity property (2.1) thus
\begin{equation}
\int \int a_{ij}(v - v_*) \partial_{v_i} f_\ast \partial_{v_j} f_\ast \geq C_{\text{coer}} \int |v > \gamma |\nabla_v f_\ast|^2 dv.
\end{equation}

For the nonlinear term arising on the on the r.h.s., we have
\begin{equation}
\frac{1}{2} \int \int a_{ij}(v - v_*) \partial_{v_i} f_\ast \partial_{v_j} f_\ast = (\gamma + 3) \int \int |v - v_*|^\gamma f_\ast f_\ast = A_1 + A_2,
\end{equation}
where
\begin{equation}
A_1 = (\gamma + 3) \int_{v_*} \int_{|v - v_*| \leq R} |v - v_*|^\gamma f_\ast f_\ast
\end{equation}
and
\begin{equation}
A_2 = (\gamma + 3) \int_{v_*} \int_{|v - v_*| \leq R} |v - v_*|^\gamma f_\ast f_\ast.
\end{equation}

For the first term in (3.3), since \( \gamma < 0 \), we have
\begin{equation}
A_1 \leq (\gamma + 3) R^\gamma \int_{v_*} \int_{|v - v_*| \leq R} f_\ast f_\ast \leq (\gamma + 3) R^\gamma m \| f \|_{L^2}^2.
\end{equation}

The second term can be estimated as follows
\begin{equation}
A_2 = (\gamma + 3) \int_{v_*} \int_{|v - v_*| \leq R} |v - v_*|^\gamma f_\ast f_\ast
= (\gamma + 3) \int_{v_*} \int_{|v - v_*| \leq R} |v - v_*|^\gamma f_\ast f_\ast
\end{equation}
\begin{equation}
\leq c_\gamma (1 + R^2)^{-\gamma/2},
\end{equation}
we get
\begin{equation}
A_2 \leq c_\gamma (1 + R^2)^{-\gamma/2} \int_{v_*} < v - v_* > \gamma f_\ast \int_{v} |v - v_*|^\gamma (< v > \gamma f_\ast)^2.
\end{equation}

We use Pitt’s inequality [4, 5, 6] to get that
\begin{equation}
\int_{v} |v - v_*|^\gamma (< v > \gamma f_\ast)^2 \leq c_{\text{pitt}} \int_{\xi} [\xi]^{-\gamma} |< v > \gamma f_\ast|^2 f(\xi)^2.
\end{equation}

In order to use Pitt’s inequality, we need that \( \gamma \in (-3, 0) \).

Recalling that
\begin{equation}
M_{-\gamma}(t) = \int_{v_*} < v_* > \gamma f_\ast,
\end{equation}
we get
\[ A_2 \leq 3c_\gamma (\gamma + 3)(1 + R^2)^{-\gamma/2} M_{-\gamma}(t) c_{\text{pitt}} \int_\xi |\xi|^{-\gamma} f(\xi)^2. \]

For any \( R_* \), write
\[ \int_\xi |\xi|^{-\gamma} f(\xi)^2 \leq \int_{|\xi| \leq R_*} |\xi|^{-\gamma} f(\xi)^2 + \int_{|\xi| \geq R_*} |\xi|^{-\gamma} f(\xi)^2, \]
and using the fact that \( f \) is in \( L^1 \), we get
\[ \int_\xi |\xi|^{-\gamma} f(\xi)^2 \leq m^2 \int_{|\xi| \leq R_*} |\xi|^{-\gamma} + \int_{|\xi| \geq R_*} |\xi|^{-\gamma} f(\xi)^2. \]

Now we need to assume \(-\gamma \leq 2\):
\[ \int_\xi |\xi|^{-\gamma} f(\xi)^2 \leq R_*^{-\gamma+2} m^2 + \frac{1}{R_*^{\gamma+2}} \int_{|\xi| \geq R_*} |\xi|^{-\gamma} f(\xi)^2 \]
\[ \leq R_*^{-\gamma+2} m^2 + c_{\text{parseval}} \frac{1}{R_*^{\gamma+2}} \|\nabla v[< v >^{\gamma/2} f]\|_{L^2}^2 \]
\[ \leq \max(m^2, c_{\text{parseval}})[R_*^{-\gamma+2} + \frac{1}{R_*^{\gamma+2}} \|\nabla v[< v >^{\gamma/2} f]\|_{L^2}^2]. \]

Optimizing w.r.t. \( R_* \), we find
\[ \int_\xi |\xi|^{-\gamma} f(\xi)^2 \leq 2 \max(m^2, c_{\text{parseval}}) \|\nabla v[< v >^{\gamma/2} f]\|_{L^2}^{\gamma+1}. \]

All in all, we have obtained, for \( \gamma \geq -2, \)
\[ A_2 \leq 3c_\gamma (\gamma + 3)(1 + R^2)^{-\gamma/2} c_{\text{pitt}} 2 \max(m^2, c_{\text{parseval}}) M_{-\gamma}(t) \|\nabla v[< v >^{\gamma/2} f]\|_{L^2}^{\gamma+1}. \]

Fix a small \( \varepsilon > 0 \). Then
\[ A_2 \leq e^{10/6} 3c_\gamma (\gamma + 3)(1 + R^2)^{-\gamma/2} c_{\text{pitt}} 2 \max(m^2, c_{\text{parseval}}) M_{-\gamma}(t) e^{-\gamma/6} \|\nabla v[< v >^{\gamma/2} f]\|_{L^2}^{\gamma+1}. \]

And apply Young’s inequality for product with \( p = \frac{10}{\gamma+6}, q = \frac{10}{4+\gamma}, \) we obtain
\[ A_2 \leq \frac{1}{q} \left( e^{10/6} 3c_\gamma (\gamma + 3)(1 + R^2)^{-\gamma/2} c_{\text{pitt}} 2 \max(m^2, c_{\text{parseval}}) M_{-\gamma}(t) \right)^q \]
\[ + \frac{1}{p} \left( e^{\gamma/6} \|\nabla v[< v >^{\gamma/2} f]\|_{L^2}^{\gamma+1}\right)^p, \]
which is also
\[ (3.5) \quad A_2 \leq \frac{4 + \gamma}{10} \left( e^{10/6} 3c_\gamma (\gamma + 3)(1 + R^2)^{-\gamma/2} c_{\text{pitt}} 2 \max(m^2, c_{\text{parseval}}) M_{-\gamma}(t) \right)^{\frac{4+\gamma}{10}} \]
\[ + \frac{\gamma + 6}{10} e^{\gamma/2} \|\nabla v[< v >^{\gamma/2} f]\|_{L^2}^2. \]

Note that there are two terms in \( A_2 \) above: \( M_{-\gamma} \) and \( \|\nabla v[< v >^{\gamma/2} f]\|_{L^2}^2. \) First, for \( \gamma \in [-2, 0], \)
\[ (3.6) \quad M_{-\gamma} = \int_\xi < v >^{-\gamma} f \leq \int_\xi (1 + v^2) f = \epsilon + e. \]

Second, we consider \( \|\nabla v[< v >^{\gamma/2} f]\|_{L^2}^2. \) Note that
\[ \nabla v[< v >^{\gamma/2} f] = \frac{\gamma}{2} < v >^{\gamma/2-2} f v + < v >^{\gamma/2} \nabla v f. \]
Now, since $\gamma < 0$, we have
\[
\| \nabla_v < v >^{\gamma/2} f \|_{L^2}^2 \leq 2 \left( \| < v >^{\gamma/2-2} f v \|_{L^2}^2 + \| < v >^{\gamma/2} \nabla_v f \|_{L^2}^2 \right) \leq \frac{\gamma^2}{2} \| f \|_{L^2}^2 + 2 \| < v >^{\gamma/2} \nabla_v f \|_{L^2}^2.
\]

(3.7)

Recall the constant $C_{coer}$ which appears in the coercive inequality (3.2). Then we can choose $\epsilon$ such that
\[
-\frac{\gamma + 6}{5} \epsilon^2 = \frac{1}{2} C_{coer},
\]
and then combining all the above results, we get
\[
\frac{d}{dt} \| f \|_{L^2}^2 + C_{coer} \| < v >^{\gamma/2} \nabla_v f \|_{L^2}^2 \leq C_1 + C_2 \| f \|_{L^2}^2,
\]
or, we just simply have
\[
\frac{d}{dt} \| f \|_{L^2}^2 \leq C_1 + C_2 \| f \|_{L^2}^2,
\]
and therefore, by directly using Gronwall’s inequality, we get
\[
\| f(t) \|_{L^2}^2 \leq e^{C_2 t} \left( \| f_0 \|_{L^2}^2 + C_1 t \right),
\]
then we have the first part of Theorem 1.1.

**Remark 3.1.** 1. By repeating the same process for higher derivatives, one can get the global existence of weak solutions. However, the bound depends on time, but the result does not require any assumption of smallness on the initial data. This is compatible with the works of Fournier-Guerin [14] where they have global existence in that case too, though in different $L^p$ spaces.

2. We work with the usual $L^2$ space but one can easily adapt our arguments for weighted $L^2$ spaces. This is done for example in the next section when $-3 < \gamma < -2$. The same remark also applies for estimation of higher derivatives as well.

4. **The case $-3 < \gamma < -2$: weighted energy estimates**

We carry out the weighted energy estimates in this section for $-3 < \gamma < -2$. Of course one can consider the general case of $\gamma \in (-3, 0)$ but recall that we have already good estimates from the previous section.

We want to estimate $g = < v >^\alpha f$ in $L^2$, and we assume that $\alpha \geq -1 - 3/2\gamma$, see below for the final arguments, explaining this value of the weight.

Multiplying the Landau equation by $< v >^\alpha g$ and setting $g = < v >^\alpha f$, we have
\[
\partial_t g = \partial_v \left\{ \int_{v_i} a_{ij} (f_s < v >^\alpha \partial_v f - g \partial_v f_s) \right\} - \left\{ \int_{v_i} a_{ij} (f_s \partial_v f - f \partial_v f_s) \right\} \partial_v < v >^\alpha = \partial_v \left\{ \int_{v_i} a_{ij} (f_s \partial_v g - g \partial_v f_s) \right\} - \partial_v \left\{ \int_{v_i} a_{ij} (f_s \partial_v f - f \partial_v f_s) \right\} < v >^\alpha - \left\{ \int_{v_i} a_{ij} (f_s \partial_v f - f \partial_v f_s) \right\} < v >^\alpha.
\]
Multiplying by \( g \) and integrating, we get
\[
\frac{d}{dt} \|g\|_{L^2}^2 = - \int_v \int_v a_{ij} f \partial_v g \partial_v g + \int_v \int_v a_{ij} \partial_v f \partial_v g \partial_v g \\
+ \int_v \int_v a_{ij} f \partial_v g \partial_v \langle v \rangle^\alpha < v >^\alpha \\
- \int_v \int_v a_{ij} f g \partial_v f \partial_v \langle v \rangle^\alpha < v >^\alpha + \int_v \int_v a_{ij} f g \partial_v f \partial_v \langle v \rangle^\alpha < v >^\alpha \\
= -I + II + III - IV + V.
\]

We then estimate each of these terms. Here \( I \) can be controlled through the coercivity estimation (2.1). More precisely, we have
\[
I \geq C_{coer} \int \langle v \rangle^\gamma |\nabla_v g|^2 dv.
\]

By a similar argument as for (3.7) with \( f \) replaced by \( g \), we have
\[
\int \langle v \rangle^\gamma |\nabla_v g|^2 dv \geq \frac{1}{2} \int \langle v \rangle^\gamma g |\nabla_v g|^2 dv - \frac{2}{4} \int g^2 dv,
\]
and thus (4.2) can be rewritten as
\[
I \geq \frac{C_{coer}}{2} \int \langle v \rangle^\gamma |\nabla_v g|^2 dv - C_{coer} \int g^2 dv.
\]

Now, as in the previous section, the term \( II \) is
\[
II = (\gamma + 3) \int \int |v - v_s|^\gamma f_s g^2 \equiv (\gamma + 3)[A + B],
\]
where
\[
A = \int \int 1_{|v - v_s| \geq \epsilon} |v - v_s|^\gamma f_s g^2 \leq Mc^\gamma \|g\|_{L^2}^2
\]
and
\[
B = \int \int 1_{|v - v_s| \leq \epsilon} |v - v_s|^\gamma f_s g^2.
\]

We further decompose \( B \) over the sets \( \{f \leq f_s\} \) and \( \{f \geq f_s\} \) to get
\[
B \leq \int \int 1_{|v - v_s| \leq \epsilon} |v - v_s|^\gamma < v >^{2\alpha} f^3 + \int \int 1_{|v - v_s| \leq \epsilon} |v - v_s|^\gamma < v >^{2\alpha} f^3,
\]
and then after direct computation we obtain
\[
B \leq Cc^{3+\gamma}(1 + \epsilon^2)^{\gamma} \int < v >^{2\alpha/3} f^3.
\]

We need to control \( < v >^{2\alpha/3} f \) in \( L^3 \) by using a control of \( < v >^\alpha f \) and of \( \nabla[< v >^{\gamma/2+\alpha} f] \) in \( L^2 \), and we will do it by applying Holder’s inequality [7].

We write \( p_1 = p_2 = p_3 = 9 \) and
\[
< v >^{2\alpha/3} f = f^{\alpha/3} \int < v >^{\alpha} f^{\gamma/3} < v >^{\gamma/2+\alpha} f \frac{d}{d\alpha} \langle v \rangle^{2\alpha/3} < v >^{2\alpha/3-2/3\gamma}. < v >^{2\alpha/3-2/3\gamma-2/3(\gamma/2+\alpha)}
\]

The last exponent is \(-2/9\alpha - \gamma/3\). Raised to the power \( 9 \) this is \(-2\alpha - 3\gamma\). We ask this number to be less than \( 2\alpha - 1 - 3/2\gamma\).

In conclusion we write, with \( \alpha \geq -1 - 3/2\gamma\),
Finally we obtain the interpolation inequality
\[(4.8)\quad \int <v>^{2\alpha/3} f^3 \leq C [\int <v>^2 f^\frac{1}{2}]^2 [\int <v>^\alpha f^\frac{2}{3}] <v>^\alpha f^\frac{2}{3} \int |\nabla(<v>^\alpha f)|^2.
\]
In conclusion, we combine (4.4)-(4.8) to get
\[(4.9)\quad II \leq mC\varepsilon^\gamma||g||^2_{L^2} + C\varepsilon^{3+\gamma}(1 + \varepsilon^2)^\alpha [\int <v>^2 f^{\frac{1}{2}} || <v>^\alpha f ||_{L^2}^{\frac{2}{3}}] \int |\nabla(<v>^\alpha f)|^2.
\]
We now analyze the term \(III\) which is given by
\[
III = \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha.
\]
We have immediately that
\[
III = \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha \partial_v + \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha \partial_v <v>^\alpha + \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha \partial_v <v>^\alpha + \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha \partial_v <v>^\alpha
\]
\[
= \frac{1}{2} \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha \partial_v <v>^\alpha + \frac{1}{2} \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha \partial_v <v>^\alpha - \frac{1}{2} \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha \partial_v <v>^\alpha
\]
\[
- \frac{1}{2} \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha \partial_v <v>^\alpha
\]
\[
(see the next section for similar arguments).
\]
Since \(f <v>^\alpha = g\), this term can be controlled like \(B\) in (4.6), thus controlled by \(II\), and we can absorb \(III\) and \(II\) together to get that
\[
II + III \leq mC\varepsilon^\gamma||g||^2_{L^2} + C\varepsilon^{3+\gamma}(1 + \varepsilon^2)^\alpha [\int <v>^2 f^{\frac{1}{2}} || <v>^\alpha f ||_{L^2}^{\frac{2}{3}}] \int |\nabla(<v>^\alpha f)|^2.
\]
Next for \(IV\), we have
\[
IV = \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha = \frac{1}{4} \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha
\]
\[
= -\frac{1}{4} \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha - \frac{1}{4} \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha + C \int_v \int_v |v - v_s|^\gamma f_s f^2 <v>^\alpha - \frac{1}{2} \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha
\]
\[
\leq C \int_v \int_v |v - v_s|^\gamma f_s f^2 <v>^\alpha - \frac{1}{2} \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha + C \int_v \int_v |v - v_s|^\gamma f_s f^2 <v>^\alpha - \frac{1}{2} \int_v \int_v a_{ij} f_s f \partial_v g \delta_{ij} <v>^\alpha
\]
and so again we can absorb it with earlier terms. One can see that \(V\) is also similar so all in all
\[
II + |III| + |IV| + |V| \leq mC\varepsilon^\gamma||g||^2_{L^2} + C\varepsilon^{3+\gamma}(1 + \varepsilon^2)^\alpha [\int <v>^2 f^{\frac{1}{2}} || <v>^\alpha f ||_{L^2}^{\frac{2}{3}}] \int |\nabla(<v>^\alpha f)|^2.
\]
By combining the above estimations, the final conclusion is that
\[
(4.10)\quad \frac{d}{dt}||g||^2_{L^2} + C_{c} ||\nabla v <v>^\gamma/2 g||^2 \leq
\]
\[ CC_{\text{coer}}\|g\|_{L^2}^2 + mC\varepsilon\|g\|_{L^2}^2 + C\varepsilon^{3+\gamma}(1 + \varepsilon^2)^\alpha \int \nabla(v > \gamma/2) g^2 dv. \]

Set \( E = \int < v >^2 f dv = m + \varepsilon \) (the summation of mass and energy) which is bounded uniformly in time. Setting

\[ X = \|g\|_{L^2}^2, \quad \| < v >^\gamma/2 g \|_{H^1}^2 = \int \| \nabla(< v >^\gamma/2 g) \|^2, \]

the above inequality (4.10) reads as

\[ \frac{d}{dt} X + CC_{\text{coer}} < v >^\gamma/2 g \|_{H^1}^2 \leq \]

\[ CC_{\text{coer}}X + mC\varepsilon^\gamma < v >^\gamma/2(1 + \varepsilon^2)^\alpha E^\gamma X^\gamma \| < v >^\gamma/2 g \|_{H^1}^2, \]

which can be also written under the form

\[ \frac{d}{dt} X \leq -\| < v >^\gamma/2 g \|_{H^1}^2 \left( C_{\text{coer}} - C\varepsilon^{3+\gamma}(1 + \varepsilon^2)^\alpha E^\gamma X^\gamma \right) + [CC_{\text{coer}} + mC\varepsilon^\gamma] X. \]

(4.11)

We want to proceed as in Toscani [20]. However, we have a major trouble in that the moment of order \( s \) of \( f \) in \( L^1 \) are not known to be uniformly bounded w.r.t. time, see Villani [22]. This means that using Nash’s inequality as in Toscani [20] at that point involves a lower bound which decays in time, and hence can be very small for large time. Since we want to get global solutions, we are going to use Pitt’s inequality instead of Nash’s inequality.

Assume that at time \( t \), we have for some \( \delta \geq 0 \)

\[ C_{\text{coer}} - C\varepsilon^{3+\gamma}(1 + \varepsilon^2)^\alpha E^\gamma X^\gamma \geq \delta, \]

that is

\[ C\varepsilon^{3+\gamma}(1 + \varepsilon^2)^\alpha E^\gamma X^\gamma \leq C_{\text{coer}} - \delta, \]

(4.12)

which is to be used for \( \delta < C_{\text{coer}} \).

Then from (4.11) we obtain

\[ \frac{d}{dt} X \leq -\| < v >^\gamma/2 g \|_{H^1}^2 \left( C_{\text{coer}} - C\varepsilon^{3+\gamma}(1 + \varepsilon^2)^\alpha E^\gamma X^\gamma \right) + [CC_{\text{coer}} + mC\varepsilon^\gamma] X. \]

Pitt’s inequality tells us that

\[ \| < v >^\gamma/2 g \|_{H^1}^2 \geq C_{\text{pitt}} \int \frac{\| g \|_{L^2}^2}{|v|^2} dv. \]

(4.13)

We are going to show a lower bound for the r.h.s. of this inequality.

We start from

\[ \int f(v) dv \leq \int_{|v| \leq R} f(v) dv + \frac{1}{R^2} e, \]

which is also

\[ \int f(v) dv \leq \int_{|v| \leq R} < v >^{-\alpha} g(v) dv + \frac{1}{R^2} e \]

\[ = \int_{|v| \leq R} < v >^{-\alpha} < v >^{-\gamma/2} |v| < v >^{\gamma/2} |v|^{-1} g(v) dv + \frac{1}{R^2} e, \]

by using Cauchy-Schwartz inequality, we obtain

\[ \int f(v) dv \leq \left[ \int_{|v| \leq R} < v >^{-2\alpha} < v >^{-\gamma} |v|^2 \right]^{1/2} \left[ \int_{|v| \leq R} < v >^{\gamma} |v|^{-2} g^2 (v) dv \right]^{1/2} + \frac{1}{R^2} e. \]

(4.15)
Recall that we have $\alpha \geq -1 - 3/2\gamma$, so the exponent
\[ \tilde{\alpha} := -2\alpha - \gamma + 2 \leq 2\gamma + 4 \in (-2, 4) \quad \text{when} \quad \gamma \in (-3, 0). \]
Thus we can estimate the upper bound inside the first integral in (4.15) to get
\[ \int f(v)dv \leq CR^{7/2}[\int <v>^\gamma |v|^{-2} g^2(v)dv]^{\frac{1}{2}} + \frac{1}{R^{2/3}}e. \]
Omitting the constant $C$, this is of the form
\[ \int f(v)dv \leq R^{7/2}A + \frac{1}{R^{2/3}}e \quad \text{with} \quad A = [\int <v>^\gamma |v|^{-2} g^2(v)dv]^{\frac{1}{2}}, \]
and we choose $R$ such that
\[ R^{7/2}A = \frac{1}{R^{2/3}}e, \]
that is
\[ R = e^{2/11}A^{-2/11}. \]
It follows that
\[ m = \int f(v)dv \leq 2R^{7/2}A = 2e^{7/11}A^{4/11}, \]
and furthermore we get
\[ A \geq Cm^{11/4}e^{-7/4}, \]
which is also
\[ (4.16) \quad \int <v>^\gamma |v|^{-2} g^2(v)dv \geq Cm^{11/2}e^{-7/2}. \]
We can now go back to our differential inequality (4.13): by Pitt’s inequality (4.14) and (4.16), we have
\[ (4.17) \quad \frac{d}{dt}X \leq -C_{pitt}Ce^{3\gamma/2}e^{-7/2}\delta + [CC_{coer} + mCe^\gamma]X = F(X). \]
Recall that we have assumed (4.12), that is
\[ \delta < C_{coer} \]
and that we want
\[ Ce^{3+\gamma}(1 + e^{3\gamma})E^{3/2}X^\delta \leq C_{coer} - \delta, \]
that is
\[ X \leq [C_{coer} - \delta]3C^{-3}e^{-(3+\gamma)(1 + e^{3\gamma})^{-3\gamma}}/E \equiv \bar{X}. \]
Now, let $X_{eq}$ be the zero of the function $F$ defined in (4.17). Assume that
\[ (4.18) \quad X(0) \leq \bar{X} \equiv \min(\bar{X}, X_{eq}). \]
Then, in view of the form of the differential inequality (4.17) and the behavior of the function $F$, it follows that for all $t > 0$
\[ X(t) \leq \bar{X}. \]
Thus we have obtain a global bound for the weighted $L^2$ norm of $f$, uniformly in time, that is, we get
the second part of Theorem 1.1.
Remark 4.1. Note that $\bar{X}$ can be as large as we want, since this quantity depends on negative powers of $\varepsilon$, which is a free parameter that we can take small. However, taking such a small $\varepsilon$, we see that $X_{eq}$ which is given by

$$X_{eq} = \frac{C_{\text{pitt}} Cm^{1/2} e^{-7/2} \delta}{[C \text{coer} + mC \varepsilon]}$$

is going to be small. Therefore by choosing $\varepsilon$ sufficiently small, we can therefore assume that $\bar{X} = X_{eq}$ and it follows that we will have $X(t) \leq X_{eq}$.

At this point, it is important to recall that for any function $f$, again using the same notation as above, one has the following interpolation inequality

$$X \geq Cm^{7/2} e^{-3/2}$$

Thus we should have

$$Cm^{7/2} e^{-3/2} \leq \frac{C_{\text{pitt}} Cm^{1/2} e^{-7/2} \delta}{[C \text{coer} + mC \varepsilon]}$$

that is

$$\frac{C_{\text{pitt}} Cm^2 e^{-2} \delta}{[C \text{coer} + mC \varepsilon]} \geq \tilde{C}.$$  

Now we note, in view of previous results on coercivity that an upper bound for $C_{\text{coer}}$ is given by

$$\max\{C_1 mR^2, C_2 \frac{(Cm)^{(\gamma+3)/3}}{R}\}$$

We choose the value of $R$, such that these two terms are equal, getting an upper bound like $m^{(9-2\gamma)/9}$.

Then it is enough to ask for

$$\frac{C_{\text{pitt}} Cm^2 e^{-2} \delta}{[Cm^{(9-2\gamma)/9} + mC \varepsilon]} \geq \tilde{C}.$$  

Then we choose a smaller $\varepsilon$ so that the second term on the denominator is bigger than the first one, so we are led to ask for

$$\frac{C_{\text{pitt}} Cm^2 e^{-2} \delta}{[2mC \varepsilon]} \geq \tilde{C}$$

and replacing $\varepsilon$ by $\delta^{1/\gamma} \varepsilon'$ with $\varepsilon'$ sufficiently small, we should require that $m e^{-2}$ should be large enough.

Remark 4.2. Nash's inequality which was used in by Toscani [20] says that for all $h$:

$$[\int |h(v)|^2 dv]^{3/2} \leq C ||h||_{L^3}^3 ||\nabla h||_{L^2}^2.$$  

In our case, $h = <v >^{3/2} <v >^\alpha f$, so we see that we need a moment estimate on $f$. That estimate, see Villani [22], grows up linearly in time, and so we get a bad estimate.

We can also use the result of Desvillettes-Villani [11] Lemma 7 on Page 43: it says that for any $h$ smooth, for all $\beta > 0$, for all $\delta > 0$, we have

$$\int h^2 <v >^{2\beta} \leq \delta \int |\nabla h|^2 + C_\delta \left( \int h <v >^{5\beta/2} \right)^2.$$
Again the choice \( h = v > \gamma/2 \) leads to ask for a value of \( \gamma \) close to zero
\[
\int h^2 < v >^{2\beta} \leq C(\int |\nabla h|^2)^{5/2} \int h < v >^{5\beta/2}.
\]

Using it, we can show that, setting
\[
\bar{\gamma} = -1 - 9/4\gamma,
\]
one has
\[
\int |\nabla < v >^{\gamma/2} \|_2^2 \geq C\|g\|_2^{10/3} M_{\bar{\gamma}}(t)^{-4/3}.
\]

The corresponding additive inequality
\[
\int h^2 < v >^{2\beta} \leq C\delta^{-5/3} \int |\nabla h|^2 + C\delta^{-5/2} h < v >^{5\beta/2}
\]
gives
\[
\| < v >^{\gamma/2} \|_{H_1}^2 \geq C\delta^{-5/3} X - C\delta^{-25/3} [M_{\bar{\gamma}}(t)]^{2},
\]
and going back to our differential inequality (4.11), we get
\[
\frac{d}{dt} X \leq -\| < v >^{\gamma/2} \|_{H_1}^2 \left\{ C_{\text{coer}} - C e^{3\gamma}(1 + \epsilon^2)^\alpha E^\frac{1}{4} X^\frac{1}{2} \right\} + [CC_{\text{coer}} + mC\epsilon^n]X.
\]

Assume that at time \( t \), we have
\[
C_{\text{coer}} - C e^{3\gamma}(1 + \epsilon^2)^\alpha E^\frac{1}{4} X^\frac{1}{2} \geq 0,
\]
that is
\[(4.19) \quad C e^{3\gamma}(1 + \epsilon^2)^\alpha E^\frac{1}{4} X^\frac{1}{2} \leq C_{\text{coer}}.
\]

Then using the above inequality, we have
\[
\frac{d}{dt} X \leq -C\delta^{-5/3} X \left\{ C_{\text{coer}} - C e^{3\gamma}(1 + \epsilon^2)^\alpha E^\frac{1}{4} X^\frac{1}{2} \right\} + C\delta^{-25/3} [M_{\bar{\gamma}}(t)]^{2} \left\{ 2C_{\text{coer}} - C e^{3\gamma}(1 + \epsilon^2)^\alpha E^\frac{1}{4} X^\frac{1}{2} \right\}
\]
\[
+ [CC_{\text{coer}} + mC\epsilon^n]X,
\]
then
\[
\frac{d}{dt} X \leq -C\delta^{-5/3} X \left\{ C_{\text{coer}} - C e^{3\gamma}(1 + \epsilon^2)^\alpha E^\frac{1}{4} X^\frac{1}{2} \right\} - C\delta^{-25/3} [M_{\bar{\gamma}}(t)]^{2} C e^{3\gamma}(1 + \epsilon^2)^\alpha E^\frac{1}{4} X^\frac{1}{2}
\]
\[
+ C\delta^{-25/3} [M_{\bar{\gamma}}(t)]^{2} C_{\text{coer}} + [CC_{\text{coer}} + mC\epsilon^n]X.
\]

We see that we still have trouble with the growth rate of \( M_{\bar{\gamma}}(t) \).
5. The case $\gamma = -3$: weighted energy estimates

We adapt the proof given in the previous Section 4, by taking below $\gamma = -3$. Again setting $g = v^\alpha f$, we have

$$\frac{d}{dt} \|g\|_{L^2}^2 = - \int v \int v_a a_{ij} f_s \partial_{v^i} g \partial_{v^j} g + \int v \int v_a a_{ij} \partial_{v^i} f_s g \partial_{v^j} g$$

$$+ \int v \int v_a a_{ij} f_s \partial_{v^i} g \partial_{v^j} < v >^\alpha$$

$$- \int v \int v_a a_{ij} f_s g \partial_{v^i} f \partial_{v^j} < v >^\alpha + \int v \int v_a a_{ij} f g \partial_{v^i} f_s \partial_{v^j} < v >^\alpha$$

$$= -I + II + III - IV + V.$$

We still have

$$I \leq \frac{C_{\text{coer}}}{2} \int v |\nabla v [< v >^2] g|^2 - CC_{\text{coer}} \int g^2.$$

For the term $II$, we have

$$II = \int v \int v_a a_{ij} \partial_{v^i} f_s g \partial_{v^j} = \frac{1}{2} \int v \int v_a a_{ij} \partial_{v^i} f_s g \partial_{v^j}^2 = 4\pi \int < v >^2 f^3 dv$$

and therefore, similarly as in Section 4, we get, with $\alpha \geq -1 - 3/2\gamma$

$$II \leq \left[ \int v < v >^2 f \right]^{4/3} < v >^\alpha f \left[ \int v |\nabla ( < v >^\alpha f) |^2 \right].$$

Next, recalling the term $III$ which is given by

$$III = \int v \int v_a a_{ij} f_s f \partial_{v^i} g \partial_{v^j} < v >^\alpha,$$

we have immediately that

$$III = \int v \int v_a a_{ij} f_s f^2 \partial_{v^i} < v >^\alpha \partial_{v^j} < v >^\alpha + \int v \int v_a a_{ij} f \partial_{v^i} f < v >^\alpha \partial_{v^j} < v >^\alpha$$

$$= \int v \int v_a a_{ij} f_s f^2 \partial_{v^i} < v >^\alpha \partial_{v^j} < v >^\alpha + \frac{1}{2} \int v \int v_a a_{ij} f \partial_{v^i} f^2 < v >^\alpha \partial_{v^j} < v >^\alpha$$

$$= \frac{1}{2} \int v \int v_a a_{ij} f_s f^2 \partial_{v^i} < v >^\alpha \partial_{v^j} < v >^\alpha - \frac{1}{2} \int v \int v_a a_{ij} f \partial_{v^i} f^2 < v >^\alpha \partial_{v^j} < v >^\alpha$$

$$- \frac{1}{2} \int v \int v_a a_{ij} f_s f^2 < v >^\alpha \partial_{v^i} \partial_{v^j} < v >^\alpha.$$

Since

$$\partial_{v^i} < v >^\alpha = \partial_{v^i} (1 + |v|^2)^{\alpha/2} = \frac{\alpha}{2} (1 + |v|^2)^{(\alpha-1)/2} 2v$$

and $|\partial_{v^i} < v >^\alpha | \leq C (1 + |v|^2)^{(\alpha-1)/2} \leq C < v >^{\alpha-1}$,

we obtain

$$III \leq C \int v \int v_a |v - v_s|^{\alpha+2} f_s f^2 < v >^{2\alpha-2} + \int v \int v_a |v - v_s|^{\alpha+1} f_s f^2 < v >^{2\alpha-1} + \int v \int v_a |v - v_s|^{\alpha+2} f_s f^2 < v >^{2\alpha-2}$$

Then, we have for any $\varepsilon > 0$ fixed

$$III \leq III_0 + III_\varepsilon.$$
where

\[ \mathcal{III}_e = C \int_v \int_{v_a} 1_{|v - v_a| \leq \varepsilon} |v - v_a|^{\gamma+2} f_s f^2 < v > 2^{\alpha-2} + \int_v \int_{v_a} 1_{|v - v_a| \leq \varepsilon} |v - v_a|^{\gamma+1} f_s f^2 < v > 2^{\alpha-1} \]

and

\[ \mathcal{III}_e = C \int_v \int_{v_a} 1_{|v - v_a| \leq \varepsilon} |v - v_a|^{\gamma+2} f_s f^2 < v > 2^{\alpha-2} + \int_v \int_{v_a} 1_{|v - v_a| \leq \varepsilon} |v - v_a|^{\gamma+1} f_s f^2 < v > 2^{\alpha-1} \]

\[ + \int_v \int_{v_a} 1_{|v - v_a| \leq \varepsilon} |v - v_a|^{\gamma+2} f_s f^2 < v > 2^{\alpha-2} . \]

For \(\mathcal{III}_e\), one has

\[ \mathcal{III}_e \leq C \int_v me^{\gamma+2} f^2 < v > 2^{\alpha-2} + \int_v me^{\gamma+1} f^2 < v > 2^{\alpha-1} + \int_v me^{\gamma+2} f^2 < v > 2^{\alpha-2} \]

and thus

\[ \mathcal{III}_e \leq C m e^{\gamma+2} + m e^{\gamma+1} \|g\|_{L^2}^2. \]

For \(\mathcal{III}_e\), splitting over the sets \(f_s \leq f\) and \(f \leq f_s\), we obtain that

\[ \mathcal{III}_e \leq A + B \]

where

\[ A \leq C \int_v \int_{v_a} 1_{|v - v_a| \leq \varepsilon} |v - v_a|^{\gamma+2} f^3 < v > 2^{\alpha-2} + \int_v \int_{v_a} 1_{|v - v_a| \leq \varepsilon} |v - v_a|^{\gamma+1} f^3 < v > 2^{\alpha-1} \]

and

\[ B \leq C \int_v \int_{v_a} 1_{|v - v_a| \leq \varepsilon} |v - v_a|^{\gamma+2} f^3 < v > 2^{\alpha-2} + \int_v \int_{v_a} 1_{|v - v_a| \leq \varepsilon} |v - v_a|^{\gamma+1} f^3 < v > 2^{\alpha-1} \]

\[ + \int_v \int_{v_a} 1_{|v - v_a| \leq \varepsilon} |v - v_a|^{\gamma+2} f^3 < v > 2^{\alpha-2} . \]

We have

\[ A \leq C e^{3+2\gamma} \int_v f^3 < v > 2^{\alpha-2} + e^{3+\gamma+1} \int_v f^3 < v > 2^{\alpha-1} + e^{3+\gamma+2} \int_v f^3 < v > 2^{\alpha-2} \]

and we see immediately that

\[ A \leq C [e^{3+2\gamma} + e^{3+\gamma+1} + e^{3+\gamma+2}] I \]

and therefore

\[ A \leq C [e^{3+2\gamma} + e^{3+\gamma+1} + e^{3+\gamma+2}] \left[ \int f^3 \| < v > 2 \right] \leq C f^{\frac{3}{2}} \int \| \nabla ( < v > 2^{\alpha+\gamma/2} f) \|^2. \]

For \(B\), the same arguments leads to
\[ B \leq C(1 + \varepsilon^2)[\varepsilon^{3+2\gamma} + \varepsilon^{3+\gamma+1} + \varepsilon^{3+\gamma+2}] \int < v >^2 f \parallel < v >^\alpha f \parallel^2 L_2 \int |\nabla( < v >^{\alpha+\gamma/2} f )|^2 \]

and thus
\[ III_\varepsilon \leq C(1 + \varepsilon^2)[\varepsilon^{3+2\gamma} + \varepsilon^{3+\gamma+1} + \varepsilon^{3+\gamma+2}] \int < v >^2 f \parallel < v >^\alpha f \parallel^2 L_2 \int |\nabla( < v >^{\alpha+\gamma/2} f )|^2. \]

In conclusion, we get
\[ III \leq C(1 + \varepsilon^2)[\varepsilon^{3+2\gamma} + \varepsilon^{3+\gamma+1} + \varepsilon^{3+\gamma+2}] \int < v >^2 f \parallel < v >^\alpha f \parallel^2 L_2 \int |\nabla( < v >^{\alpha+\gamma/2} f )|^2 + Cm[\varepsilon^{\gamma+2} + \varepsilon^{\gamma+1}] \parallel g \parallel^2_{L_2}. \]

The same arguments can be applied to all other terms, and thus we get
\[ II + III + IV + |V| \leq C\left\{1 + (1 + \varepsilon^2)[\varepsilon^{3+2\gamma} + \varepsilon^{3+\gamma+1} + \varepsilon^{3+\gamma+2}]\right\} \int < v >^2 f \parallel < v >^\alpha f \parallel^2 L_2 \int |\nabla( < v >^{\alpha+\gamma/2} f )|^2 + Cm\tilde{O}(\varepsilon) \parallel g \parallel^2_{L_2}. \]

By combining the above estimations, the final conclusion is that
\[ \frac{d}{dt} \parallel g \parallel^2_{L_2} + C_{\text{coer}} \int \nabla v [ < v >^{\gamma/2} g ] \leq CC_{\text{coer}} \parallel g \parallel^2_{L_2} + C\left\{1 + O(\varepsilon)\right\} \int < v >^2 f \parallel < v >^\alpha f \parallel^2 L_2 \int |\nabla( < v >^{\alpha+\gamma/2} f )|^2 + Cm\tilde{O}(\varepsilon) \parallel g \parallel^2_{L_2}. \]

Again setting \( E = \int < v >^2 f dv = m + e \), which is bounded uniformly in time, let
\[ X = \parallel g \parallel^2_{L_2}, \quad \parallel < v >^{\gamma/2} g \parallel^2_{H_1} = \int |\nabla( < v >^{\gamma/2} g )|^2, \]
then we have obtained
\[ \frac{d}{dt} X \leq -\parallel < v >^{\gamma/2} g \parallel^2_{H_1} \left\{ C_{\text{coer}} - C(1 + O(\varepsilon))E^{\frac{\gamma}{2}}X^{\frac{\gamma}{2}} \right\} + [CC_{\text{coer}} + mC\tilde{O}(\varepsilon)]X. \]

At this point, we can use the arguments of Section 4. Assume that at time \( t \), we have for some \( \delta \geq 0 \)
\[ C_{\text{coer}} - C(1 + O(\varepsilon))E^{\frac{\gamma}{2}}X^{\frac{\gamma}{2}} \geq \delta, \]
that is
\[ C(1 + O(\varepsilon))E^{\frac{\gamma}{2}}X^{\frac{\gamma}{2}} \leq C_{\text{coer}} - \delta, \]
which is to be used for \( \delta < C_{\text{coer}} \).
Then we obtain, using again Pitt’s inequality (4.14) and (4.16),
\[ \frac{d}{dt} X \leq -C_{pitt} Cm^{11/2} e^{-7/2} \delta + [CC_{coer} + m\tilde{O}(1)]X = F(X). \]  

Recall that we have assumed 
\[ \delta < C_{coer} \]
and that we want 
\[ C(1 + O(\varepsilon))E^{1/2} X^{1/2} \leq C_{coer} - \delta, \]
that is 
\[ X \leq [C_{coer} - \delta]^3 C^{-3} (1 + O(\varepsilon))^{-3} / E \equiv \bar{X}. \]
Now, let \( X_{eq} \) be the zero of the function \( F \) defined in (5.7). Then assume that 
\[ X(0) \leq \bar{X} \equiv \min(\bar{X}, X_{eq}), \]
then in view of the form of the differential inequality and the behaviour of function \( F \), it follows that for all \( t > 0 \):
\[ X(t) \leq \bar{X}. \]
Thus we have obtain a global bound for the weighted \( L^2 \) norm of \( f \), uniformly in time, that is, we get the second part of Theorem 1.1, for the specific case \( \gamma = -3 \).

6. The case \(-3 < \gamma < -2\): local estimates

The energy estimate in Section 3 holds for \( \gamma \geq -2 \). For the case \( \gamma \in (-3, -2) \), we recall (3.1)
\[ \frac{d}{dt} \| f \|_{L^2}^2 + \int \int a_{ij}(v - v_\star) f_\star \partial v_i f_\partial v_j f = \frac{1}{2} \int \int a_{ij}(v - v_\star) \partial v_i f_\star \partial v_j f^2, \]
and from (3.2) and (3.7) we have
\[ \int \int a_{ij}(v - v_\star) \partial v_i f_\star \partial v_j f \geq \frac{C_{coer}}{2} \int \int |\nabla (\langle v >^{1/2}) f|^2 dv - C \int f^2 dv. \]
Next, we estimate
\[ \frac{1}{2} \int \int a_{ij}(v - v_\star) \partial v_i f_\star \partial v_j f^2 = (\gamma + 3) \int v_i \int |v - v_\star|^\gamma f_\star f^2. \]
The problem is that it looks like a \( L^3 \) norm, but at that point we need a \( L^1 \) weighted estimation. Up to now these bounds grow linearly in time [22] and so are not enough.

Let us fix a positive function of time \( \phi(t) \). We split \( A \) into two terms (forgetting the positive constant \( \gamma + 3 \) in front of \( A \))
\[ A = A_1 + A_2, \]
where
\[ A_1 = \int v_i \int |v - v_\star|^\gamma f_\star f^2 \]
and
\[ A_2 = \int v_i \int |v - v_\star|^\gamma f_\star f^2. \]

For \( A_1 \), since \( \gamma < 0 \), we have
\[ A_1 \leq \int v_i \int \phi(t)^\gamma f_\star f^2 \leq m\phi(t)^\gamma \| f \|_{L^2}^2. \]

For \( A_2 \), we split again according to whether or not \( f \leq f_\star \) to get
\[ A_2 \leq 2 \int v_i \int |v - v_\star|^\gamma f_\star f^3 \leq 2C\phi(t)^{3+\gamma} \| f \|_{L^2}^3. \]
Next, we are going to work on $\|f\|_{L^3}$: if $f = f_1 f_2 f_3$, then, with $\frac{1}{3} = \frac{1}{p_1} + \frac{1}{p_2} + \frac{1}{p_3}$, we have

$$
\|f\|_{L^3} \leq \|f_1\|_{L^{p_1}} \|f_2\|_{L^{p_2}} \|f_3\|_{L^{p_3}}.
$$

Now write

$$
1 = \frac{1}{p_1} + \frac{2}{p_2} + \frac{6}{p_3},
$$

so

$$
f = f^\frac{1}{p_1} \cdot f^\frac{2}{p_2} \cdot f^\frac{6}{p_3}.
$$

Thus

$$
= f^\frac{1}{n_1} < v > \frac{2}{p_2} \cdot (v > f)^{\frac{6}{p_3}}
$$

$$
= (v > f)^{\frac{6}{p_3}} \cdot \frac{1}{n_1} \cdot \frac{2}{n_2} \cdot (v > f)^{\frac{6}{n_3}}
$$

with evident notations. We make the choice $p_1 = p_2 = p_3 = 9$ for reasons linked to Sobolev inequality. Then we get

$$
\|f\|_{L^3}^3 \leq \|f_1\|_{L^{p_1}}^3 \|f_2\|_{L^{p_2}}^3 \|f_3\|_{L^{p_3}}^3
$$

$$
\leq [\int < v > \frac{1}{p_1} \cdot \frac{2}{p_2} \cdot \frac{6}{p_3} \cdot [\int f^2] \cdot [\int f^\frac{6}{p_3}]^\frac{1}{p_3}.
$$

Sobolev inequality tells us that

$$
[\int (v > f)^\frac{6}{p_3}]^\frac{1}{p_3} \leq \int \nabla (v > f)^2.
$$

Finally, we have obtained

$$
\|f\|_{L^3}^3 \leq C [\int < v > \frac{1}{p_1} \cdot \frac{2}{p_2} \cdot \frac{6}{p_3} \cdot [\int f^2] \cdot [\int \nabla (v > f)^2],
$$

and thus (6.2) becomes

$$
A_2 \leq C \phi(t) [\int < v > \frac{1}{p_1} \cdot \frac{2}{p_2} \cdot \frac{6}{p_3} \cdot [\int f^2] \cdot [\int \nabla (v > f)^2].
$$

From Villani [22] (Appendix B), in our case $\gamma \geq -3$, i.e., $-3 \leq 9$, we have

(6.3)

$$
M_{-3\gamma} := [\int < v > \frac{1}{p_1} \cdot \frac{2}{p_2} \cdot \frac{6}{p_3} \cdot [\int f^2] \cdot [\int \nabla (v > f)^2],
$$

then finally

$$
A_2 \leq C \phi(t) [\int < v > \frac{1}{p_1} \cdot \frac{2}{p_2} \cdot \frac{6}{p_3} \cdot [\int f^2] \cdot [\int \nabla (v > f)^2].
$$

Now we choose $\phi(t)$ such that (for some $\varepsilon$ fixed)

$$
\phi(t) [\int < v > \frac{1}{p_1} \cdot \frac{2}{p_2} \cdot \frac{6}{p_3} \cdot [\int f^2] \cdot [\int \nabla (v > f)^2] \leq \varepsilon,
$$

that is

$$
\phi(t) \leq e^{\frac{1}{12 \gamma}} (1 + t)^\frac{1}{12 \gamma},
$$

or, for simplicity, we just choose

(6.4)

$$
\phi(t) = e^{\frac{1}{12 \gamma}} (1 + t)^\frac{1}{12 \gamma}.
$$

With this choice, we get that

$$
A_2 \leq C \varepsilon \|f\|_{L^2}^\frac{3}{p_3} \int \nabla (v > f)^2.
$$

Recall (6.1) to get also

$$
A_1 \leq m \phi(t) [\int f^2] \leq m \varepsilon \frac{12}{12 \gamma} (1 + t)^\frac{12}{12 \gamma} \|f\|_{L^2}^2.
$$
In conclusion, we get:

\begin{equation}
A \leq m \exp^{\frac{\gamma}{3\gamma}} (1 + t) \frac{\alpha}{3\gamma} \|f\|_{L^2}^3 + C\|f\|_{L^2}^2 \int |\nabla(< v >^\frac{\gamma}{3\gamma} f)|^2.
\end{equation}

Fix $t$, and optimize w.r.t. $\varepsilon$. The above term is of the form

\[ e^{\frac{\gamma}{3\gamma}} B + \varepsilon D \]

with

\[ B = m(1 + t) \frac{\alpha}{3\gamma} \|f\|_{L^2}^3, \quad D = C\|f\|_{L^2}^2 \int |\nabla(< v >^\frac{\gamma}{3\gamma} f)|^2. \]

We have equality in (6.5) if

\[ e^{\frac{\gamma}{3\gamma}} B = \varepsilon D, \]

that is

\[ \varepsilon = B^{\frac{3\gamma}{9}} D^{-\frac{3\gamma}{9}}. \]

With this value, we get from (6.5) that

\[ A \leq 2\varepsilon D = 2B^{\frac{3\gamma}{9}} D^{-\frac{3\gamma}{9}} D = 2B^{\frac{3\gamma}{9}} D^{-\frac{\gamma}{9}}, \]

that is

\[ A \leq 2[m(1 + t) \frac{\alpha}{3\gamma} \|f\|_{L^2}^3]^{\frac{3\gamma}{9}} [C\|f\|_{L^2}^2 \int |\nabla(< v >^\frac{\gamma}{3\gamma} f)|^2]^\frac{4}{9} \]

\[ \leq C(1 + t)^{\frac{\gamma}{9}} \int |\nabla(< v >^\frac{\gamma}{3\gamma} f)|^2 \|f\|_{L^2}^{\frac{18+4\gamma}{9}}. \]

We choose another $\varepsilon$ and write

\[ A \leq C(1 + t)^{\frac{\gamma}{9}} \int |\nabla(< v >^\frac{\gamma}{3\gamma} f)|^2 \|f\|_{L^2}^{\frac{18+4\gamma}{9}} \]

\[ \leq C\varepsilon^{\frac{\gamma}{9}} (1 + t)^{\frac{\gamma}{9}} e^{-\varepsilon^3} \|\nabla(< v >^\frac{\gamma}{3\gamma} f)|^2 \|f\|_{L^2}^{\frac{18+4\gamma}{9}}, \]

use Young’s inequality for product of the first two factors (i.e. without the $L^2$ norm) with $p = -3/\gamma$ and $p' = 3/(3 + \gamma)$:

\[ A \leq \left( \frac{e^3}{p} \int |\nabla(< v >^\frac{\gamma}{3\gamma} f)|^2 + C\varepsilon^{\frac{\gamma}{9}} (1 + t)^{-\frac{\gamma}{3\gamma}} \right) \|f\|_{L^2}^{\frac{18+4\gamma}{9}}. \]

Combine the above estimates, we get a differential inequality

\begin{equation}
\frac{d}{dt} \|f\|_{L^2}^2 \leq -\left(c_{\text{coer}} - \frac{e^3}{p} \|f\|_{L^2}^{\frac{18+4\gamma}{9}} \right) \int |\nabla(< v >^\frac{\gamma}{3\gamma} f)|^2 + C\|f\|_{L^2}^2 + C(1 + t)^{-\frac{\gamma}{3\gamma}} \|f\|_{L^2}^{\frac{18+4\gamma}{9}}.
\end{equation}

We see that we have trouble with the growth rate of coefficient, due to lack of uniform in time bound of the moment in (6.3). The differential inequality (6.6) yields a local estimate of a weak solution in this case and thus we have the following weaker conclusion

**Proposition 6.1.** Let $\gamma \in (-3, -2)$. Let the initial data $f_0 \in L^2(\mathbb{R}^3)$, then we have a local in time a priori estimate (6.6) on a weak solution in $L^2$.

**Remark 6.2.** We emphasize here that when $\gamma \in (-3, -2)$, the a priori estimate in $L^2$ is only local, unless we can get a better moment estimates in $L^1$, that is, uniformly bounded w.r.t. time.
7. Proof of Proposition 1.2

Multiplying the Landau equation by \( f \) and integrating, we have
\[
\frac{d}{dt} \|f\|_{L^2}^2 + \int \int a_{ij}(v - v_z) f_s \partial_{v_i} f \partial_{v_j} f = \frac{1}{2} \int \int a_{ij}(v - v_z) \partial_{v_i} f_s \partial_{v_j} f^2.
\]
Moreover, as usual now, we have also (note here that we keep the weight on the second term on the r.h.s.)
\[
\int \int a_{ij}(v - v_z) f_s \partial_{v_i} f \partial_{v_j} f \geq \frac{C_{\text{coer}}}{2} \int |\nabla_v (< v >^{\gamma/2}) f|^2 dv - C \int < v >^{-2} f^2 dv.
\]
and
\[
\frac{1}{2} \int \int a_{ij}(v - v_z) \partial_{v_i} f_s \partial_{v_j} f = (\gamma + 3) \int \int |v - v_z|^\gamma f_s f^2.
\]
All in all, we have
\[
\frac{d}{dt} \|f\|_{L^2}^2 + \frac{C_{\text{coer}}}{2} \int |\nabla_v (< v >^{\gamma/2}) f|^2 dv \leq (\gamma + 3) \int \int |v - v_z|^\gamma f_s f^2 + C \int < v >^{-2} f^2 dv.
\]
Define the first term on the r.h.s. as \( NLT \) (non linear term), that is
\[
NLT = (\gamma + 3) \int \int |v - v_z|^\gamma f_s f^2.
\]
From now on, we will omit or abbreviate any non important constant. For any \( \varepsilon > 0 \), we can write
\[
NLT \leq C \int f^2(v) \left\{ \int |v - v_z|^\gamma 1_{|v - v_z| \leq \varepsilon} f_s + \int |v - v_z|^\gamma 1_{|v - v_z| > \varepsilon} f_s \right\}.
\]
Then, we can use classical estimations on the truncated Riez potentials, see [26] for example, involving the usual maximal function \( Mf(v) \) to get
\[
NLT \leq C \int f^2(v) \left\{ \varepsilon^{3+\gamma} Mf(v) + \varepsilon^\gamma m \right\}.
\]
Fixing \( v \), we optimize w.r.t. \( \varepsilon \) to find that
\[
NLT \leq C m^{1+\gamma/3} \int f^2(v) Mf(v)^{-\gamma/3} \leq C C m^{1+\gamma/3} \int Mf(v)^{2-\gamma/3} \leq C m^{1+\gamma/3} \int f^{2-\gamma/3},
\]
by using our assumption on the values of \( \gamma \).

Let \( q \) be defined by \( q = 2 - \gamma/3 = \frac{6-\gamma}{3} > 1 \). Note that we have also \( q_1 = \frac{q}{2} = \frac{6-\gamma}{6} > 1 \). The conjugate exponent is given by \( q'_1 = \frac{6-\gamma}{2-\gamma} \). We can then use Holder inequality together with the fact that \( \gamma - 2 \leq -3 \) to get
\[
C \int < v >^{-2} f^2 dv \leq C \left( \int f^{\frac{6-\gamma}{3}} \right)^{\frac{3}{6-\gamma}}.
\]
Using the conservation of mass, again skipping all constants, we have obtained
\[
\frac{d}{dt} \|f\|_{L^2}^2 + \frac{C_{\text{coer}}}{2} \int |\nabla_v (< v >^{\gamma/2}) f|^2 dv \leq C_1 + C_2 \int f^{6-\gamma} dv.
\]
Now the idea is this: we want to control the l.h.s. term by the r.h.s., and so we will use some Nash Gagliardo Nirenberg type inequalities, [19] for example.
We have a slight issue connected to moments (because on the l.h.s., we have only some control of a negative power weight in Sobolev space), but let’s forget this point for the moment. Firstly recall that (we are using homogeneous Sobolev spaces) $H_s \subset L^m$ for $0 < s < 3/2$ and $m = \frac{6-s}{3-2s}$. We want to choose $m = q = \frac{6-s}{3-2s}$. This gives the value of $s$ as $s = \frac{3\gamma}{2\gamma-12}$. Note that we have $0 < s < 1$.

If this is the case, it follows that $\|f\|_{H_s}^q \leq C\|f\|_{H_s}^q$.

On the other hand, by using classical ideas for proving Nash inequality (Fourier transform, optimizing for small and big frequencies), one can show that (for $s < 1$ which is the case here)

$$\|f\|_{H_s} \leq C m^{1-\frac{q}{s}(3+2\gamma)} \left( \int |\nabla f|^2 \right)^{\frac{1}{2}(3+2\gamma)}$$

and thus

$$\|f\|_{H_s}^q \leq C m^{1-\frac{q}{s}(3+2\gamma)} q \left( \int |\nabla f|^2 \right)^{\frac{1}{2}(3+2\gamma)}.$$ 

A little computation shows that $\mu \equiv \frac{m}{q}(3 + 2\gamma)q = \frac{1}{4}(3 - \gamma)$ which gives $\mu < 1$ iff $\gamma > -2$. Then (up to the control of weights), we can absorb the r.h.s. by the l.h.s in inequality (7.1).

Now to get everything rigorous, and in particular to take care of the loss of weights appearing on the l.h.s, we need to interpolate with a weighted $L^1$ space the r.h.s. of (7.1) (as well we can also use some improved type Nash inequalities).

Starting with a fixed $\varepsilon > 0$, we look for $\alpha \in (0, 1)$ such that $q = \alpha (1 + (1 - \alpha)(q + \varepsilon))$. We find that

$$\alpha = \frac{\varepsilon}{q + \varepsilon - 1}$$

and

$$1 - \alpha = \frac{q - 1}{q + \varepsilon - 1}.$$ 

It follows that

$$\int f^q = \int f^{q_{1+\varepsilon}(1-\alpha)(q+\varepsilon)} = \int f^{\alpha q_{1-\alpha}(q+\varepsilon)} = \int [v > \frac{1}{q_{1-\alpha}(q+\varepsilon)} f]^\alpha [v > \gamma/2 f]^{(1-\alpha)(q+\varepsilon)}$$

and using Holder inequality, we get

$$\int f^q \leq \left\{ \frac{M_{\frac{q}{q_{1-\alpha}(q+\varepsilon)}}}{q_{1-\alpha}(q+\varepsilon)} \right\}^\alpha \left\{ \int [v > \gamma/2 f]^{q+\varepsilon} \right\}^{1-\alpha},$$

which upon using another small $\bar{\varepsilon} > 0$, yields

$$\int f^q \leq C(\bar{\varepsilon})M_{\frac{q}{q_{1-\alpha}(q+\varepsilon)}}(t) + \bar{\varepsilon} \int [v > \gamma/2 f]^{q+\varepsilon}.$$ 

Set $q_{\varepsilon} = q + \varepsilon$, $\gamma_{\varepsilon} = \gamma - 3\varepsilon$ and $s_{\varepsilon} = \frac{2\gamma_{\varepsilon}}{2\gamma_{\varepsilon}-12}$.

Then, we still have

$$\|g\|_{L^{q_{\varepsilon}}}^{q_{\varepsilon}} \leq C m^{1-\frac{q_{\varepsilon}}{s_{\varepsilon}}(3+2s_{\varepsilon})q_{\varepsilon}} \left( \int |\nabla g|^2 \right)^{\frac{1}{2}(3+2s_{\varepsilon})q_{\varepsilon}}.$$ 

Then note that $\mu_{\varepsilon} = \frac{1}{10}(3 + 2s_{\varepsilon})q_{\varepsilon} = \frac{1}{4}[3 - \gamma_{\varepsilon}] = \frac{1}{4}[3 - \gamma + 3\varepsilon]$. Since we have assumed $\gamma > -2$, one obtains that $\mu_{\varepsilon} \leq 1$ when choosing any $\varepsilon$ such that $0 < \varepsilon \leq \frac{2\gamma}{3}$. Therefore we choose exactly $\varepsilon = \frac{2\gamma}{3}$.

With this value of $\varepsilon$, we find that $\alpha = \frac{2\gamma}{3}$, $1 - \alpha = \frac{2\gamma}{3}$, $q + \varepsilon = \frac{8}{3}$, and thus all in all, we find that

$$\int f^q \leq C(\bar{\varepsilon})M_{\frac{q}{q_{1-\alpha}(q+\varepsilon)}}(t) + \bar{\varepsilon} C(\bar{\varepsilon}) + \bar{\varepsilon} M(\alpha, m) \int |\nabla [v > \gamma/2 f]|^2,$$

and therefore choosing $\bar{\varepsilon}$ small enough, we find that, going back to our estimation inequality
\[ \|f\|_{L^2}^2(t) \leq C(1 + t)^2 \]

which ends the proof of Proposition 1.2.

**Remark 7.1.**

1. Of course, we get also a Sobolev estimation as well. Moreover, it might be also possible to have direct estimation of the nonlinear term by using Holder inequality, together with the standard Nash’s inequality.

2. Note that the growth of this \( L^2 \) estimate is linked with the moment estimate. One can also get weighted \( L^2 \) estimate and more generally \( L^p \) estimates. For example, one can show that the nonlinear term is estimated by \( \int f^{p-\gamma} \). But it does not seem to be possible to improve the range of values of \( \gamma \). However, working with large \( p \) seem to require less moments on \( f \).

3. By interpolating also with \( L^2 \), as in previous sections, one can get also local estimates for all \( \gamma > -3 \).
