Monopoles on 3 dimensional AC manifolds

Goncalo Oliveira
Duke University and Imperial College London

2 August 2013

Abstract

We construct monopoles in any asymptotically conical (AC) 3-manifold $X$ with $b_2^+(X) = 0$. For sufficiently large mass, our construction covers an open set in the moduli space of monopoles.

We also give a more general construction of Dirac monopoles in any AC manifold, which may be useful for generalizing our result to the case when $b_2^+(X) \neq 0$.

Let $(X^3, g)$ be an asymptotically conical (AC) manifold, $P \to X$ an $SU(2)$ bundle and $g_P$ the associated adjoint bundle, equipped with an $Ad$-invariant metric. A pair $(A, \Phi)$ where $A$ is a connection on $P$ and $\Phi \in \Omega^0(X, g_P)$ called the Higgs field is said to be a monopole if they satisfy

\[ \ast F_A - \nabla_A \Phi. \]

Since $(X, g)$ is AC it is the interior of a manifold with boundary $\overline{X}$. Let $\Sigma = \partial \overline{X}$ and denote by $\Sigma_i$, for $i \in \{1, ..., b_0(\Sigma)\}$ its connected components. We shall refer to the $i$-th end of $X$ has the one modeled on $(1, +\infty) \times \Sigma_i$, and let $\rho$ denote a radial coordinate which at each end is identified with the radial distance along the cone. A monopole is said to have finite mass if at each end the norm of the Higgs field converges to a constant $m_i \in \mathbb{R}^+$. Under such conditions one can prove \cite{6}, \cite{10}

\[ |\Phi| = m_i - \frac{k_i^O}{2\rho} + O(\rho^{-2}), \]

for some $m_i \in \mathbb{R}$ and $k_i^O \in \mathbb{N}$. We shall call $k = k_1^O + ... + k_{b_0(\Sigma)}^O$ the total charge of the monopole and tuple $m = (m_1, ..., m_{b_0(\Sigma)}) \in \mathbb{R}^{b_0(\Sigma)}$ the mass.

Remark 1. In fact one can prove that under the assumption of finite mass the Higgs field becomes converges to a parallel section of $g_P$ at each end. In fact if it does not vanish, i.e. $m_i \neq 0$ the connection $A$ converges to reducible HYM connections at the ends. Having this in mind we remark that each of the $k_i^O$ is the degree of the complex line bundles over the $\Sigma_i$’s associated with each of such reductions.

Definition 1. Denote the space of total charge $k \in \mathbb{Z}$ and mass $m \in \mathbb{Z}^{b_0(\Sigma)}$ configurations by $C_{k,m}(X, g)$. The space of mass $m$ and total charge $k$ monopoles is denoted by $M_{k,m}$ and consists on those $(A, \Phi) \in C_{k,m}$ such that equation \[0.1\]

Let $\mathcal{G}$ be the space of gauge transformations $g \in C^\infty(X, SU(2))$, which converge to the identity ate the ends of $X$. Equation \[0.1\] is invariant under the $\mathcal{G}$-action and we define

\[ \mathcal{M}_{k,m}(X, g) = M_{k,m}(X, g)/\mathcal{G}, \]

called the moduli space of total charge $k$ and mass $m$ monopoles.
The main results of this paper are

**Theorem 1.** Let \( k \in \mathbb{Z} \) and \((X, g)\) be an asymptotically conical 3-manifold with \( b^2(X) = 0 \) (notice this implies \( b^0(\Sigma) = 1 \)). Then, there is \( \mu \in \mathbb{R} \), such that if \( m \geq \mu \) and \( X^k(m) \subset X^k \) denotes the open set defined by
\[
X^k(m) = \left\{ (p_1, \ldots, p_k) \in X^k \mid \text{dist}(p_i, p_j) > 4m^{-\frac{1}{2}}, \text{ for } i \neq j \right\},
\]
there is a map
\[
\tilde{h} : X^k(m) \times H^1(X, S^1) \times T^k \to M_{k,m},
\]
i.e. its image consists of monopoles.

Moreover, this construction is then showed to descend well to the moduli space of monopoles

**Theorem 2.** The map \( h \) in equation (0.3) descends to a local diffeomorphism
\[
h : X^k(m) \times H^1(X, S^1) \times T^k \to M_{k,m}
\]

**Remark 2.**

1. We may interpret the monopoles in the image of the map \( h \) as well being formed by \( k \) well separated monopoles. Then one may think of the parameters in \( X^k(m) \times H^1(X, S^1) \times T^k \) used in their construction as follows: The points \((p_1, \ldots, p_k) \in X^k(m)\) denote the location of the \( k \) monopoles, \( T^k \) denotes local phases assigned to each of these and \( H^1(X, S^1) \) a possible twist with a flat connection, i.e. a usual vector potential whose strength (magnetic field) vanishes inside the superconductor filling in \( X \).

2. In [7] Kottke computes the dimension of the moduli space of monopoles with fixed mass on an asymptotically conical 3 manifolds and obtains the formula \( \dim(M_{m,k}) = 4k + \frac{1}{2}b^1(\Sigma) \). The long exact sequence on cohomology \( H_c(X) \to H(X) \to H(\Sigma) \) and the duality \( H^*_c \cong (H^{3-*})^\ast \), can be used to rewrite Kottke’s formula as
\[
\dim(M_{m,k}) = 4k + b^1(X) - b^2(X) + b^0(\Sigma) - 1,
\]
and the construction described here gives a good geometric interpretation of all these parameters in an open set in \( M_{m,k} \). Even though it will be evident that the elements of \( b^2(X) \) obstruct the gluing construction, the author believes the analysis here can be changed to take these into account and extend theorems [7] and [2] to the case of \( b^2(X) \neq 0 \).

We shall now give a short outline of the paper and of the proof of the results above. The first result of the paper is a construction of certain Dirac monopoles. This requires definition [4] which constructs \( X^k(m) \subset X^k \) as the intersection of a \( 3k - b^2(X) \) dimensional submanifold with a big open set in \( X^k \). Then, for each element in \( X^k(m) \times H^0(\Sigma, S^1)/S^1 \times H^1(X, S^1) \) theorem [8] constructs a Dirac monopole. Later in section section 2.1 proposition [4], these Dirac Monopoles are smoothed out around the singular points \( p_i \in X \). To smooth each singular point requires an element of \( S^1 \) and this construction gives a map
\[
H : X^k(m) \times H^0(\Sigma, S^1)/S^1 \times H^1(X, S^1) \times T^k \to C_{k,m}(X, g),
\]
whose image consists of approximate solutions to the Bogomolny equations. Still in in section 2.1 we estimate the error term \( e_0 = e(A_0, \Phi_0) \) of a configuration in the image of the map \( H \). Section [8] constructs a general setup to solve the monopole equation by deforming an approximate solution \((A_0, \Phi_0)\) in the image.
of the map $H$. More precisely, section 3.1 constructs Function Spaces depending on the approximate solution $(A_0, \Phi_0)$. These are specially adapted to uniformly invert the linearized equation, make the the error term $\epsilon_0$ small, and handle the nonlinearities. Then, in section 3.2 the linearised equation is shown to admit a right inverse with uniformly bounded norm on the previously defined function spaces. Finally, section 3.3 solves the monopole equation, see proposition 6, by using a special version of the contraction mapping principle.

To the author’s knowledge the first reference in the literature investigating monopoles on a large class of 3-manifolds is Braam’s paper [1], which explores monopoles in asymptotically hyperbolic manifolds. Monopoles on asymptotically Euclidean 3-manifolds have been investigated by Floer [3] and Ernst [2]. The main motivation for all these is the possibility of using the moduli space of monopoles on noncompact 3-manifolds to attack problems in 3-dimensional topology. This tries to imitate the way instantons have shed light on 4 dimensional topology and this possibility have remained unexplored. In this direction here we have extended Floer’s and Ernst to the more general class of asymptotically conical manifolds where we are able to describe an open set of the moduli space.

0.1 Acknowledgements

The work presented here was done while I was a PhD student at Imperial College London. I would like to thank Simon Donaldson for guidance and encouragement. I would also like to thank Chris Kottke, Lorenzo Foscolo and Michael Singer for discussions. I am very grateful for having had my PhD supported by the FCT doctoral grant with reference SFRH / BD / 68756 / 2010.

1 Preliminary Remarks

1.1 Linearized Operator

Let $(\nabla_A, \Phi)$ be a connection and Higgs field, not necessarily satisfying the Bogomolny equations. For such a configuration the quantity $\epsilon_0 = *F_{A_0} - \nabla_A \Phi$ may be nonzero. The linearized Bogomolny equation fits into a sequence

\[
\Omega^0(\mathfrak{su}(P)) \xrightarrow{d_1} \Omega^1(\mathfrak{su}(P)) \oplus \Omega^0(\mathfrak{su}(P)) \xrightarrow{d_2} \Omega^1(\mathfrak{su}(P)),
\]

with $d_1 \xi = (-\nabla_A \xi, -[\Phi, \xi])$ and

\[
d_2(a, \phi) = *d_A a - \nabla_A \phi - [a, \Phi].
\]

Their formal adjoints are given by $d_1^*(a, \phi) = -\nabla^*_A a + [\Phi, \phi]$ and $d_2^*(a) = (*d_A a + [a, \Phi], -\nabla^*_A a)$. If $(A, \Phi)$ is a monopole then the sequence in (1.1) is actually an elliptic complex and so the operator $D = d_2 \oplus d_1^*$ acting on sections of $(\Lambda^1 \oplus \Lambda^0)(\mathfrak{su}(P))$ is elliptic. Its formal adjoint is $D^* = d_2^* \oplus d_1^*$ and these can be written as

\[
D = \begin{pmatrix} *d_A & -\nabla_A \\ -d_A^* & 0 \end{pmatrix} + [\Phi, .] \quad D^* = D - 2[\Phi, .].
\]

Lemma 1. (Standard Weitzenböck) Let $\nabla_A$ be a connection and $u \in \Omega^1(\mathfrak{su}(2)) \oplus \Omega^0(\mathfrak{su}(2))$, then

\[
\Delta_A u = \nabla^*_A \nabla_A u + F^W(u) + \text{Ric}^W(u).
\]

Where $F^W(a, \phi) = (*[F_A \wedge a], 0)$ and $\text{Ric}^W(a, \phi) = (\text{Ric}(a), 0)$.
Lemma 2. (Monopole Weitzenböck) Let \((\nabla_A, \Phi)\) be a connection and an Higgs Field. Let \(u \in \Omega^1(\mathfrak{su}(2)) \oplus \Omega^0(\mathfrak{su}(2))\), then

\[
DD^*u = \nabla_A^* \nabla_A u - [\Phi, \Phi] + R_{\mathcal{A}}^W(u) + \epsilon_0^W(u)
\]

\[
D^* Du = DD^* u + 2(\nabla_A \Phi)^W(u).
\]

Where \(b^W(a, \phi) = ([a \wedge b] - [b, \phi] + [(b, a)])\) and \(b\) is either \(\epsilon_0 = \ast F_A - \nabla_A \Phi, \ast \text{Ric}\) or \((\epsilon_0 + 2d_A \Phi)\).

If \((A, \Phi) = (A_0 + a, \Phi_0 + \phi)\) for suitable \(u = (a, \phi) \in \Omega^1(\mathfrak{su}(P)) \oplus \Omega^0(\mathfrak{su}(P))\) is a monopole, then

\[
\epsilon_0 + D(u) + Q(u, u) = 0,
\]

where the operator \(D\) is as above and \(Q(u, u) = \left(\ast [a \wedge a] - [a, \phi]\right).

1.2 Some Further Analytical Remarks

There is a scale invariance in the Bogomolny equation which is inherited from the conformal invariance of the ASD equations in 4 dimensions. The precise result is

Proposition 1. Let \((\nabla_A, \Phi)\) be a monopole on \((M^3, g)\), where \(M^3\) is a Riemannian 3 manifold. Then \((\nabla_A, \delta^{-1} \Phi)\) is a monopole for \((M^3, \tilde{g} = \delta^2 g)\).

Proof. In general, if \(\omega\) is a \(k\) form and \(\ast\) the Hodge operator for the metric \(\tilde{g}\), then \(\ast \omega = \delta^{n-2k} \ast \omega\) \((n = 3)\). This implies that \(\ast F_A = \delta^{-1} \ast F_A = \delta^{-1} \nabla_A \Phi\), and the result follows. \(\square\)

The Yang-Mills-Higgs (YMH) Energy is defined on a precompact set \(U \subset X\) as

\[
E_U = \frac{1}{2} \int_U |\nabla_A \Phi|^2 + |F_A|^2.
\]

The Euler Lagrange equations are \(d_A^* F_A = [d_A \Phi, \Phi], \Delta_{d_A} \Phi = 0\). It is well known that monopoles not solve these, but also minimize the YMH energy on \(X\). The energy over a precompact set \(U\) with smooth boundary is given by the flux \(\int_{\partial U} (\Phi, F_A)\) and so the total energy is given by

\[
E_U = 4\pi \sum_{i=1}^k m_i k_i^O.
\]

The next two results will be used later in this chapter for the construction of monopoles on AC 3 manifolds.

Lemma 3. Let \(\nabla_A\) be a metric compatible connection on an Hermitian vector bundle \(E\) over an AC manifold \((X^3, g)\). Then, for all \(\alpha \in [1, 3]\), there is a constant \(c_K(\alpha) > 0\), such that

\[
\left(\int_X |u|^2 + |dvol_g|^{2\alpha / \rho^3}\right)^{\frac{1}{2\alpha}} \leq c_K(\alpha) \left(\int_X |\nabla_A u|^2\right)^{\frac{1}{2}}
\]

for all smooth and compactly supported section \(u\). In particular for \(\alpha = 3, 1\) one has respectively \(\|u\|_{L^6}^2 \leq c_K \|\nabla_A u\|_{L^2}^2\) and \(\|\rho^{-1} u\|_{L^2}^2 \leq c_K \|\nabla_A u\|_{L^2}^2\).
Proof. Kato’s inequality $|\nabla |u|| \leq |\nabla A u|$, holds pointwise for all irreducible Hermitian connections. The proof follows from combining this with corollary 1.3 in [4]. 

Lemma 4. In the conditions of lemma 3. Let $u$ be a section such that $\nabla A u \in L^2$, then there is a covariant constant limit $u|_{\Sigma} \in \Gamma(\Sigma, E|_{\Sigma})$. Moreover, on the cone $C(\Sigma_i)$ over each end there is an inequality

$$\| u|_{\Sigma_i} \|_{L^{2^*}_0} \leq C_1 \| \nabla A u \|_{L^2}.$$ 

Proof. This lemma is a particular case of propositions A.0.16 and A.0.17 in the Appendix A to [10]. 

1.3 Monopoles in $(\mathbb{R}^3, g_E)$

In this short section $\mathcal{M}_{k,m}$ denotes the moduli space of charge $k \in \mathbb{Z}$ and mass $m \in \mathbb{R}^+$ monopoles in Euclidean $\mathbb{R}^3$. In the construction of the approximate solution it will be important to scale these monopoles. This is due to the fact that given $\lambda \in \mathbb{R}^+$, there is a bijection $\mathcal{M}_{k,m} \to \mathcal{M}_{k,\lambda m}$, which can be described as follows. Let $\lambda \in \mathbb{R}^+$ and $(A, \Phi)$ a monopole on $(\mathbb{R}^3, g_E)$, then $(A, \lambda \Phi)$ is a monopole on $(\mathbb{R}^3, \lambda^{-2} g_E)$. Using the scaling map $\exp_\lambda(x) = \lambda x$ on $\mathbb{R}^3$ we define

$$\Phi_\lambda = \lambda \exp_\lambda \Phi, \quad A_\lambda = \exp_\lambda A, \quad (g_E)_\lambda = \lambda^{-2} \exp_\lambda g_E.$$ 

Since the Euclidean metric is invariant under scaling $(g_E)_\lambda = g_E$, and $(A_\lambda, \Phi_\lambda)$ is a monopole for the Euclidean metric. However, the monopole $(A_\lambda, \Phi_\lambda)$ no longer has mass $m$ but mass $\lambda m$.

Fix a framing $\eta : \mathbb{C}^2|_{\mathbb{R}^3 \setminus \{0\}} \to H^k \oplus H^{-k}$ which identifies the limiting Higgs Field and connection with the pullbacks via $\eta$ of those determined by the unique $SU(2)$ invariant configurations on the Hopf bundle $H$. These framings are unique up to a factor of $\mathbb{S}^1/\mathbb{Z}_k$, where $\mathbb{S}^1$ denotes the automorphism group of $H$ equipped with its unique $SU(2)$ invariant connection. Moreover, such a framing $\eta$ also gives an isomorphism $\mathbb{S}^2|_{\mathbb{R}^3 \setminus \{0\}} \to \mathbb{R}^+ \oplus \mathbb{R}^2$. Hence, given a section $a$ of the adjoint bundle, one can write $a = a_\parallel \oplus a_\perp$ according to this splitting. These components will be respectively called the longitudinal and the transverse one.

Example 1. Fixing a framing gives a model for the Hopf bundle $H$, this together with the map that to a charge one monopole assigns the zero of the Higgs field, gives a map $M_{1,1} \cong \mathbb{R}^3 \times \mathbb{S}^1$. Hence, one can consider monopoles with a fixed center and then $M_{1,1} \cong \mathbb{S}^1$.

There is a unique spherically symmetric monopole with mass 1, $\mathbb{R}^3$, which we shall call the BPS monopole and denote

**Definition 2.** There is a unique spherically symmetric monopole with mass 1, $\mathbb{R}^3$, which we shall call the BPS monopole and denote it by $(A_{BPS}, \Phi_{BPS})$. Then, any element $\eta$ in $M_{1,1} \cong \mathbb{S}^1$ is a framing $\eta : \mathbb{C}^2|_{\mathbb{R}^3 \setminus \{0\}} \to H \oplus H^{-1}$ which at infinity identifies the connection $A_{BPS}$ with the direct sum of the unique $SU(2)$ invariant connection on $H$. Moreover, one remarks that $|\Phi_{BPS}| > 1/2$ outside the ball of radius $R$ in $\mathbb{R}^3$.

The following lemma is an important tool for estimating the error term of the approximate solution

**Lemma 5.** Let $(A, \Phi)$ be the Dirac monopole on $\mathbb{R}^3$ with mass 1. Then, for all $k$ and $(A, \Phi) \in C_{k,1}$, there is $\nu$, such that

$$| (\Phi - \Phi_D) \parallel = O(r^\nu), \quad | (\Phi - \Phi_D) \perp = O(e^{-r}), \quad |A - A_D| = O(e^{-r})$$

on $\mathbb{R}^3 \setminus \{0\}$. Moreover, if $k = 1$ i.e. for the BPS monopole then $\nu = -\infty$, i.e. $|\Phi - \Phi_D| = O(e^{-r})$.  

5
2 Dirac Monopoles

This section contains the linear analysis necessary for the construction of Dirac monopoles, the main result come in the form of theorem 3 below.

Given a total charge \( k \in \mathbb{N} \) and mass \( m = (m_1, \ldots, m_{b_0(\Sigma)}) \in \mathbb{R}^{b_0(\Sigma)} \) we shall construct Dirac monopoles with this mass and total charge. We shall call

\[
m_0(m) = \frac{1}{b_0(\Sigma)} \sum_{i=1}^{b_0(\Sigma)} m_i,
\]

the average mass of the monopole.

**Definition 3.** Let \( p = (p_1, \ldots, p_k) \in X^k \) and define the current \( \delta \in (C_0^\infty(X))^* \), by

\[
\delta(f) = \sum_{i=1}^{k} f(p_i)
\]

for a compactly supported \( f \in C_0^\infty(X) \).

These points can be repeated and so the current \( \delta \) has multiplicities giving a vector \( k^I = (k^I_1, \ldots, k^I_{2^k-\text{pts}}) \in \mathbb{Z}^{2^k-\text{pts}} \) of charges generating a flux that must then leave \( X \) through its ends with some charges \( k^O \in \mathbb{Z}^{b_0(\Sigma)} \) with \( |k^I| = |k^O| \). The Laplacian \( \Delta \) acts \( C_0^\infty(X) \), and one can consider its transpose operator, also denoted by \( \Delta \) acting on \( H \in (C_0^\infty(X))^* \) by \( \Delta H(g) = H(\Delta g) \), for all \( g \in C_0^\infty(X) \).

**Proposition 2.** Let \( (p_1, \ldots, p_k) \in X^k \) and \( (m_1, \ldots, m_{b_0(\Sigma)}) \in H^0(\Sigma, \mathbb{R}) \), then there is a current \( H^D \in (C_0^\infty(X))^* \) such that \( \Delta H^D = \delta \). This can be represented by an integral operator

\[
H^D(f) = \int_X f \phi^D,
\]

where \( \phi^D \) is an harmonic function on \( X \setminus \{p_1, \ldots, p_k\} \) and \( k^O \in \mathbb{R}^{b_0(\Sigma)} \) satisfying \( |k^O| = |k^I| \) such that

\[
(2.1) \quad \phi^D \big|_{U(p_i)} = -\frac{k^I_i}{2r} + O(r^0)
\]

\[
(2.2) \quad \phi^D \big|_{U(\Sigma_i)} = m_i - \frac{k^O_i}{Vol(\Sigma_i)} \frac{1}{r} + O(r^{-2}).
\]

Where \( U(p_i) \) and \( U(\Sigma_i) \) respectively denote a neighborhood of \( p_i \) and the \( i \)-th end.

The proof is an exercise in the calculus of variations, which below is hidden by the use of the Riesz representation theorem. Before the proof two lemmas are required. Let \( V \) denote the space of functions \( f : X \to \mathbb{R} \), with \( \nabla f \in L^2 \). Given \( g \in L^1_{\text{loc}} \) a function \( u \in V \) is called a weak solution to \( \Delta u = g \) if for all test functions \( \psi \in C_0^\infty(X) \)

\[
\langle du, d\psi \rangle_{L^2} = \int_X g \psi.
\]

Recall that if \( f : X \to \mathbb{R} \) is such that \( \nabla f \in L^2 \), then according to lemma 4 the limit of \( f \) along any end exists, is constant and will be denoted by \( f|_{\Sigma_i} \) on each connected component \( \Sigma_i \) of \( \Sigma \).
Lemma 6. Let \( g \in L^6(X) \), then there is a unique weak solution \( u_g \in V \) of
\[
\Delta u_g = g \\
u_g|_{\Sigma_i} = 0.
\]

Proof. Those \( f \in V \) such that \( f|_{\Sigma_i} \) vanishes form an Hilbert space \( H \), namely the completion of \( C^\infty_0(X) \)
in the inner product \( \langle f_1, f_2 \rangle_H = \int_X df_1 \wedge df_2 \), for \( f_1, f_2 \in C^\infty_0(X) \). To find a weak solution \( u_g \in H \) one proves the linear functional \( f \mapsto \int_X gf \) is bounded on \( H \). This follows from
\[
|\int_X gf| \leq \|g\|_{L^6} \|f\|_{L^6} \leq \|g\|_{L^6} \|f\|_H,
\]
where we used first Hölder’s inequality and then the Sobolev inequality from lemma 3. The Riesz representation theorem gives an element \( u_g \in H \) such that \( \langle u_g, f \rangle_H = \int_X gf \), for all \( f \in H \), i.e. \( u_g \) is a weak solution to the problem. To prove uniqueness suppose there are two solutions \( u, v \in H \). Then \( w = u - v \) is an harmonic function in \( H \). Moreover, since \( w \in H \) we have \( dw \in L^2 \) and \( w|_{\Sigma_i} = 0 \) and so there is a sequence \( R_i \to \infty \) such that \( w|_{r^{-1}(R_i)} = o(R_i^{-1/2}) \) and \( dw|_{R_i} = o(R_i^{-3/2}) \). So one can compute
\[
0 = \int_X w \Delta w = -\int_X (d(w * dw) - dw \wedge *dw) = \lim_{i \to \infty} \int_{r^{-1}(R_i)} w * dw + \|w\|^2_H = \|w\|^2_H,
\]
and conclude \( w \in H \) with \( dw = 0 \) and so \( w = 0 \), i.e \( u = v \). \( \Box \)

Corollary 1. Given \( m = (m_1, ..., m_{b^0(\Sigma)}) \in \mathbb{R}^{b^0(\Sigma)} \), there is a unique solution \( u_m \in V \) of the problem
\[
\Delta u_m = 0 \\
u_m|_{\Sigma_i} = m_i, \; i = 1, ..., b^0(\Sigma).
\]

Proof. Let \( g \in C^\infty(X) \) with \( g|_{\Sigma} = m \) be a smooth extension of \( m \) to the whole \( X \), such that \( \Delta g \in L^6 \). Then from lemma 6 one concludes that there is a unique solution \( \tilde{u} \in H \) to the problem \( \Delta \tilde{u} = \Delta g \). Then the solution \( u_m \) is given by setting \( u_m = g - \tilde{u} \). \( \Box \)

Corollary 2. Let \( g \in L^6(X) \) and \( m = (m_1, ..., m_{b^0(\Sigma)}) \in \mathbb{R}^{b^0(\Sigma)} \), there is a unique solution \( u \in V \) of the problem
\[
\Delta u = g \\
u|_{\Sigma_i} = m_i, \; i = 1, ..., b^0(\Sigma).
\]

Proof. Let \( u_g \in H \subset V \) be the solution to \( \Delta u_g = g \), \( u_g|_{\Sigma} = 0 \) given by lemma 3 and let \( u_m \in V \) be the solution to \( \Delta u_m = 0 \), \( u_m|_{\Sigma} = m \) given by corollary 1. Then \( u = u_g + u_m \) is the desired solution and the uniqueness follows from a similar argument as the one used in the proof of lemma 6. \( \Box \)
Proof. (of proposition 3) There is a 1-parameter family of smoothings of the current \( \delta \) represented by smooth 3-forms \( \delta^\epsilon dvol \), such that \( \delta(f) = \lim_{\epsilon \to 0} \int_X \delta^\epsilon f \), for all \( f \in C_0^{\infty}(X) \). The \( \delta^\epsilon \) can be chosen to have uniformly bounded \( L^1 \)-norm, i.e. \( ||\delta^\epsilon||_{L^1} = \int_X |\delta^\epsilon| dvol_X = k \), and to be supported on small \( \epsilon > 0 \) balls around the points \( p_i \). At this point it must be remarked that the original distribution \( \delta \) does not make sense as an element of \( H^* \), as elements of \( H \) need not be bounded. However, it does make sense as a current, i.e. \( \delta \in (C_0^{\infty}(X))^* \) as \( ||\delta^\epsilon||_{L^1} = k \) is bounded independently of \( \epsilon \) and so

\[
|\delta(f)| = \left| \lim_{\epsilon \to 0} \int_X \delta^\epsilon f \right| \leq k ||f||_{L^\infty}.
\]

The trick now is to understand that for each \( \epsilon \) the norm \( ||\delta^\epsilon||_{L^\frac{2}{3}} \) is still bounded, however not independently of \( \epsilon \). Then corollary 2 gives a family of functions \( \phi^\epsilon_D \in V \), weakly solving

\[
\Delta \phi^\epsilon_D = \delta^\epsilon \quad \phi^\epsilon_D|_{\Sigma_i} = m_i, \ i = 1, ..., b^0(\Sigma),
\]

and with \( \phi^\epsilon_D \) unique for each \( \epsilon \). Since the \( \delta^\epsilon \) are smooth, elliptic regularity guarantees that so are the \( \phi^\epsilon_D \). However it must be remarked that the norm \( ||\phi^\epsilon_D||_H \) is not uniformly bounded independently of \( \epsilon \). For \( f \in C_0^{\infty}(X) \)

\[
\delta(f) = \lim_{\epsilon \to 0} \int_X \delta^\epsilon f = \lim_{\epsilon \to 0} \langle \phi_D^\epsilon, f \rangle_H,
\]

and since for all \( \epsilon \) we have \( \langle \phi_D^\epsilon, f \rangle_H = \int_X \delta^\epsilon f \leq k ||f||_H \), the weak limit as \( \epsilon \to 0 \) of the \( \phi_D^\epsilon \) exists and gives a current \( \phi^D \) weakly solving \( \Delta \phi^D = \Delta \delta \). This current is represented by an unbounded function which we still denote by \( \phi^D \) such that the integral \( \int_X f \phi^D = \lim_{\epsilon \to 0} \int_X \phi_D^\epsilon f \) is well defined for all \( f \in C_0^{\infty}(X) \). As the \( L^1 \)-norm of the \( \delta^\epsilon \) is bounded independently of \( \epsilon \) and \( \Delta \phi^\epsilon_D = 0 \) outside an \( \epsilon \)-neighborhood of the \( p_i \)'s one respectively concludes that \( \phi^D \in L^1_{loc} \) and is smooth away from the \( p_i \)'s.

Moreover, as the metric is asymptotically conical \( \phi_D \) behaves as \( \Sigma_i \) at each end. Locally on small balls \( U_{p_i} \) around each \( p_i \) the metric is approximately Euclidean, so that on these \( \Sigma_i \) holds. The last thing to be checked is the identity \( |k^I| = |k^O| \), this follows from integrating

\[
0 = \int_{X \backslash \{p_1, ..., p_{n-pts.}\}} \Delta \phi^D dvol = - \int_{X \backslash \{p_1, ..., p_{n-pts.}\}} d \ast \phi^D
\]

\[
= \lim_{\epsilon \to 0} \sum_{\epsilon-pts.} \int_{\partial B\epsilon(p_i)} \ast \phi^D \leq \lim_{r \to \infty} \sum_{\epsilon-pts.} \int_{\Sigma_i^r} \ast \phi^D
\]

\[
= \sum_{\epsilon-pts.} k^I_{\epsilon} - \sum_{\epsilon-ends.} k^O_{\epsilon},
\]

where we use Stokes’ theorem and the local behavior of \( \phi^D \) both at the singular points \( p_i \) and at the ends \( \Sigma_i \).

Remark 3. The distribution \( \delta \) can be extended from the smooth compactly supported functions to those \( f \) which are smooth and bounded. Then, the second Green’s identity gives

\[
\delta(f) = \left\{ \begin{array}{ll}
\int_X df \wedge \ast \phi^D, & \text{if } \phi^D \text{ is supported}\,

\int_X f \Delta \phi^D + \int_{\Sigma} f \ast \phi^D,
\end{array} \right.
\]

8
where the integrals involving $\phi^D$ can be interpreted as the corresponding limits as $\epsilon \to 0$. Since, $*d\phi_D|_{\Sigma_i} = \frac{k_i^O}{\text{Vol}(\Sigma_i)} d\text{vol}_{\Sigma_i}$,

$$\int_{\Sigma_i} f * d\phi_D = \sum_{i=1}^{b_0(\Sigma_i)} k_i^O \frac{1}{\text{Vol}(\Sigma_i)} \int_{\Sigma_i} f,$$

moreover if $df \in L^2$, then $f$ converges to a constant by lemma 4 and the formula above simplifies to

$$\int_{\Sigma_i} f * d\phi_D = \sum_{i=1}^{b_0(\Sigma_i)} k_i^O f|_{\Sigma_i}. \quad \text{One still needs to show } \Delta\phi_D = \sum_{i=1}^{\sharp-\text{pts}} \delta(p_i), \text{ but this can be achieved by the limit } \lim_{\epsilon \to 0} \Delta\phi_D^\epsilon \text{ this can be seen to converge uniformly to zero outside the } p_i \text{’s leaving } \sum_{i=1}^{\sharp-\text{pts}} \delta(p_i). \text{ To check that } \Delta\phi_D \text{ does not get any contribution at } \infty \text{ one needs to use the fact that the metric is asymptotically conical and so at the } i\text{-th end}

$$\phi^\epsilon_D = m_i - \frac{k_i^O}{\text{Vol}(\Sigma_i)} \frac{1}{\sqrt{r^2 + \epsilon^2}} + o(r^{-2}),$$

one computes

$$(2.3) \quad \Delta\phi^\epsilon_D = \frac{\partial^2 \phi^\epsilon_D}{\partial r^2} + \frac{2}{r} \frac{\partial \phi^\epsilon_D}{\partial r} + \ldots

= \frac{k_i^O}{\text{Vol}(\Sigma_i)} \frac{3\epsilon^2}{(r^2 + \epsilon^2)^{\frac{3}{2}}} + \ldots$$

and so the integration of $\Delta\phi^\epsilon_D$ times a bounded function is finite and then converges to zero as $\epsilon \to 0$. Inserting all this information one concludes that $\delta$ extends as

$$\delta(f) = \sum_{i=1}^{\sharp-\text{pts}} k_i^O f(p_i) - \sum_{i=1}^{\sharp-\text{ends}} k_i^O \frac{1}{\text{Vol}(\Sigma_i)} \int_{\Sigma_i} f.$$  

The next goal is to construct a line bundle with connection on $U = X \backslash \{p_i\}_{i=1}^{\sharp-\text{pts}}$.

**Proposition 3.** Let $U = X \backslash \{p_i\}_{i=1}^{\sharp-\text{pts}}$ and $F_D = *d\phi_D$. Then $F_D$ is a closed 2-form on $U$ and the class $[F_D] \in H^2(U, \mathbb{R}/\mathbb{Z})$ is uniquely determined by a class $[F_X] \in H^2(X, \mathbb{R}/\mathbb{Z})$. Moreover, the $F_D$ is the curvature of a connection on a line bundle over $U$ if and only if the class $[F_X]$ vanishes.

**Proof.** Let $R$ be one of the following Abelian Groups $\mathbb{Z}, \mathbb{R}, \mathbb{R}/\mathbb{Z}$. Since $H^1(U, \{p_i\}), H^2(U, \mathbb{R})$ and $H^3(U, R)$ all vanish, the long exact sequence for the pair $U = X \backslash \{p_i\}_{i=1}^{\sharp-\text{pts}} \cup_{i=1}^{\sharp-\text{pts}} U_{p_i}$, gives

$$0 \to H^2(U, R) \to H^2(U, R) \to \bigoplus_{i=1}^{\sharp-\text{pts}} H^2(U, \{p_i\}, R) \to 0.$$  

The 2-form $F_D = *d\phi_D$ is closed in $U$, since $dF_D = - * \Delta\phi^D$ which vanishes in $U$. It represents a class in $H^2(U, \mathbb{R})$ and is the curvature of a connection on a line bundle over $U$ if and only if this class has integer periods, equivalently if $[F_D]$ vanishes in $H^2(U, \mathbb{R}/\mathbb{Z})$. In fact, from the definition of $\phi_D$ one knows that the image of $[F_D]$ in $H^2(U, \{p_i\}, \mathbb{R}/\mathbb{Z})$ vanishes, since

$$\int_{\partial U_{p_i}} F_D = \int_{U_{p_i}} dF_D = \int_{U_{p_i}} \delta = k_i^i \in \mathbb{Z}.$$  

So by exactness of the Mayer-Vietoris sequence, the class $[F_D] \in H^2(U, \mathbb{R}/\mathbb{Z})$ is the image of a class in $[F_X] \in H^2(X, \mathbb{R}/\mathbb{Z})$ and for $F_D$ to be the curvature of a connection on a line bundle over $U$ one just needs $[F_X]$ to vanish as well.  

\[\square\]
Moreover, for any two different connections \( \nabla \) and \( \nabla' \) one can consider \( L = \nabla - \nabla' \) with \( c, m \in \mathbb{R}^b(\Sigma) \) given by

\[
c(m_1, \ldots, m_b) = (m + c), \quad m \in \mathbb{R}^b(\Sigma)
\]

for \( c \in \mathbb{R} \) and let \( H^0(\Sigma, R)/R \) denote the space of \( R \)-equivalence classes.

2. Define the map

\[
b : X^k \times H^0(\Sigma, \mathbb{R})/\mathbb{R} \to H^2(X, \mathbb{R}/\mathbb{Z})
\]

\[
(p, [m]) \mapsto [F_X],
\]

where \([F_X]\) is the class determined via proposition 3. Moreover, fixing the mass \( m \) denote by \( b[m] \) the map that to \( p \in X^k \) assigns \( b[m](p) = b(p, [m]) \in H^2(X, \mathbb{R}/\mathbb{Z}) \).

The map \( b \) above is indeed well defined, since changing the mass \( m = (m_1, \ldots, m_b) \) by an overall constant amounts to add this constant to \( \phi_D \). Hence \( F_D = *d\phi_D \) remains unchanged and proposition 3 can be rephrased as

**Corollary 3.** Given \( (p, [m]) \in X^k \times H^0(\Sigma, \mathbb{R})/\mathbb{R} \), these determine a line bundle \( L \) over \( U = X \setminus \{p_1, \ldots, p_k\} \) with connection \( \nabla_D \) and curvature \( F_D = *d\phi_D \) if and only if \( b[p, [m]] = 0 \).

**Remark 4.** To make a connection with Hitchin’s point of view in [5] one must regard the formal sum of points \( \sum_{i=1}^k p_i \) as a sort of divisor on the 3-dimensional Riemannian manifold \( (X, g) \). This divisor can be equivalently regarded as a flat gerbe, since \( H^3(X, \mathbb{Z}) = 0 \) as \( X \) is noncompact. The holonomy of the flat connection represents a class in \( H^2(X, \mathbb{R}/\mathbb{Z}) \) and one has the following equivalent statements. 1. The holonomy vanishes. 2. The flat gerbe is trivial. 3 The divisor is linearly trivial. 3 There is a Dirac monopole on \( U \).

**Theorem 3.** Let \( m \in H^0(\Sigma, \mathbb{R}) \), then for each

\[
(p, [c], \alpha) \in b^{-1}[m](0) \times H^0(\Sigma, \mathbb{S}^1)/\mathbb{S}^1 \times H^1(X, \mathbb{S}^1)
\]

there is a reducible \( SU(2) \) bundle \( L \oplus L^{-1} \) over \( X \setminus \{p_1, \ldots, p_k\} \) equipped with a charge \( k \) and mass \( m \) Dirac monopole \( (A_D, \Phi_D) \). In particular, if \( b_2 = 0 \), then the map \( b \) vanishes and there is such a Dirac monopole for all \( p \in X^k \).

Moreover, for any two different \( (p, [c], \alpha) \) and \( (p', [c'], \alpha') \) the Dirac monopoles associated with these are not related by any gauge transformation \( g \in C^\infty(X, \mathbb{S}^1) \) converging to 1 over the ends.

**Proof.** This has 4 steps.

1. From proposition 2 one constructs the function \( \phi_D \), which determines a 2-form via \( F_D = *d\phi_D \). Then, from proposition 3 or equivalently corollary 3 one knows that the two form \( F_D \) is the curvature of a connection \( \nabla_D \) on a line bundle \( L \) over \( X \setminus \{p_1, \ldots, p_k\} \) if and only if \( b(p, [m]) = 0 \).

We also note that the connections \( \nabla_D \) associated with different tuples of points are obviously gauge inequivalent and may possibly live in different line bundles.
2. For each representative \( c = (c_1, \ldots, c_n) \in H^0(\Sigma, \mathbb{R}) \) of the class \([c] \in H^0(\Sigma, \mathbb{S}^1)/\mathbb{S}^1\), corollary \( \text{[4]} \) gives a unique harmonic function \( f_c \) which converges at the ends \( \Sigma_i \) to \( c_i \). Moreover, different representatives \( c \) give rise to harmonic functions \( f_c \) which differ by a constant, so the one form \( a = 2\pi if_c \) is uniquely determined by the class \([c] \in H^0(\Sigma, \mathbb{R})/\mathbb{R}\). Then, we upgrade the connection \( \nabla_D \) to \( \nabla_D + a \), its curvature is
\[
F_{\nabla_D+a} = F_D + da = F_D,
\]
since \( da = d^2 f_c = 0 \). This shows the pair \((\nabla_D + a, \phi_D)\) is still a monopole on \( L \rightarrow X \setminus \{p_1, \ldots, p_k\} \). Note that the connections \( \nabla_D \) and \( \nabla_D + a \) are related by the gauge transformation \( g = e^{if_c} \), which only converges to 1 if the class \([c] \in H^0(\Sigma, \mathbb{R})\) vanishes. In order to ease notation in what follows the monopole \((\nabla_D + a, \phi_D)\) will still be denoted by \((\nabla_D, \phi_D)\).

3. A class \( \alpha \in H^1(X, \mathbb{S}^1) \) represents a gauge equivalence class of flat connections \( \nabla^F \) on a torsion line bundle \( L^F \) over \( X \). One can now twist this with the Dirac monopole without changing the Higgs field. This gives the line bundle \( L \otimes L^F \), which one still denotes by \( L \), equipped with the connection \( \nabla = \nabla_D \otimes 1 + 1 \otimes \nabla^F \). The curvature of this connection remains unchanged and so it still satisfies the Bogomolny equation \( *F_D = d\phi_D \).

4. To finish the proof increase the gauge group to \( SU(2) \), either by equipping \( L \) with a metric and considering the principal bundle \( P = \mathbb{S}^1(L) \times_{U(1)} SU(2) \), or by considering the vector bundle \( L \oplus L^{-1} \), associated with \( P \) through the standard representation of \( SU(2) \) in \( \mathbb{C}^2 \). Then, the adjoint bundle is \( g_P = \mathbb{R} \oplus L^2 \). Define the connection \( A_D = \nabla_D \oplus (-\nabla_D) \) on \( E \) and Higgs field \( \Phi_D = \phi_D \oplus 0 \), these do satisfy the monopole equations on \( U \) and have Dirac type singularities at the points \( p_i \), for \( i = 1, \ldots, k \).

\[ \square \]

### 2.1 The Approximate Solution

This section constructs an approximate solution to the monopole equations in proposition \( \text{[4]} \) whose error term is estimated in lemma \( \text{[8]} \). Recall the map \( b \) from definition in \( \text{[4]} \) and theorem \( \text{[3]} \) which proves that if \( p = (p_1, \ldots, p_k) \in X^k \) and \( m \in H^0(\Sigma, \mathbb{R}) \) are such that \( b(p, [m]) = 0 \), then one can construct a reducible Dirac Monopole \( (A_D, \Phi_D) \) on an \( SU(2) \)-bundle \( L \oplus L^{-1} \) over \( X \setminus \{p_1, \ldots, p_k\} \). Before proceeding to the construction of an approximate solution it is helpful to show how one can make this Dirac monopole have very large Higgs field in a big open set in \( X \).

**Lemma 7.** Let \([m] \in H^0(\Sigma, \mathbb{R})/\mathbb{R}\) be an \( \mathbb{R} \)-equivalence class. Then, there is \( \mu \in \mathbb{R} \) (depending on the metric \( g \) and the class \([m]\)) with the following property. Let \( \phi_D \) the Higgs field constructed in proposition \( \text{[2]} \) associated with a representative \( m \in [m] \) with average mass \( m_0(m) \geq \mu \). Then, there is \( \epsilon_i = \sqrt{\frac{10k_i}{8m_0}} \)
\[
\phi_D \geq \frac{m_0}{2},
\]
on \( U_i = X \setminus \bigcup_{i=1}^{k} B_{\epsilon_i}(p_i) \).

**Proof.** Let \( m_{\text{init}} \in H^0(\Sigma, \mathbb{R}) \) be a representative in the class \([m]\) with average mass \( m_0(m_{\text{init}}) = 0 \). Then, equation \( \text{[2.1]} \) in proposition \( \text{[2]} \) implies that there are \( c_i \in \mathbb{R} \) and a positive \( \delta < \text{inj}(X, g) \) such that on \( B_{\delta}(p_i) \),
\[
\phi_D(r) = c_i - \frac{k_i}{2r} + O(r).
\]
One can always add a constant $m_0$ and construct a new Dirac monopole $\phi_D$ with mass $m = m_{\text{init}} + (m_0, \ldots, m_0)$. Then $[m] = [m_{\text{init}}]$, but $m_0([m]) = m_0$. Then, by possibly changing the constants $c_i$ by some term linear in $\delta$ one can assume that on each $B_\delta(p_i)$

$$\phi_D \geq m_0 + c_i - \frac{b_i}{2r},$$

and is increasing along the radial coordinate. The goal now is to increase $m_0$ in order to find $\epsilon < \delta$, such that for $r \in (\epsilon, \delta)$ one has $\phi_D \geq \frac{m_0}{2}$. As the $c_i$’s do not change with $m_0$, one can change $m_0$ so that $m_0 + c_i \geq \frac{9}{10} m_0$, i.e. $m_0 \geq 10 \max_i (-c_i)$. Then it is enough to solve

$$\frac{9}{10} m_0 - \frac{b_i}{2r} \geq \frac{m_0}{2},$$

which gives $r \geq \frac{10 k}{8 m_0}$. This quantity is strictly decreasing with increasing $m_0$, and so we can arrange for $\sqrt{\frac{10 k}{8 m_0}} << \delta$, as $\delta$ does not depend on $m_0$. Then, set $\epsilon_i = \sqrt{\frac{10 k}{8 m_0}} > \frac{10 k}{8 m_0}$ for big $m_0$. Then, one has

$$\phi_D|_{\partial B_{\epsilon_i}} \geq \frac{m_0}{2},$$

so that the problem is reduced to show that $\phi_D \geq \frac{m_0}{2}$ on the whole of $U_\epsilon = X \cup_i B_{\epsilon_i}(p_i)$. This follows from the fact that $\phi_D$ is harmonic on $U_\epsilon$ and so by the maximum principle it has no interior maximum or minimum. These are attained at the ends of $X$ or at the spheres $\partial B_{\epsilon_i}$. Since, the $\epsilon_i$’s where chosen smaller than $\delta$ and on each $B_\delta(p_i)$, $\phi_D$ is increasing with $r = \text{dist}(p_i, \cdot)$, the conclusion is that the minimum is attained at the inner boundaries and so $\phi_D \geq \frac{m_0}{2}$ on $X \setminus \cup_i B_{\epsilon_i}(p_i)$. \hfill \Box

**Definition 5.** Let $m \in H^0(\Sigma, \mathbb{R})$ be a configuration with positive average mass $m_0$. Define $X^k(m)$ as the set of $p = (p_1, \ldots, p_k) \in X^k$ such that $b(p, [m]) = 0$ and $\text{dist}(p_i, p_j) \geq \frac{4}{\sqrt{m_0}}$, for all distinct $i, j \in \{1, \ldots, k\}$.

**Remark 5.** In the case where $b^2(X) = 0$, the map $b$ vanishes identically and $H^0(\Sigma, \mathbb{R}) \cong \mathbb{R}$ so $X^k(m)$ is the open subset of $X^k$ where the distinct points are at distance more than $4/\sqrt{m}$ apart. However, in general this is the intersection of this open set $U(m)$ with a submanifold $b^{-1}_m(0)$ of $X^k$ of dimension $3k - b^2(X)$. Moreover, this submanifold only depends on the equivalence class $[m]$ and so by increasing $m_0(m)$ one can make the open set $U(m)$ as large as one wants and so $X^k(m) = b^{-1}_m(0) \cap U(m)$ is certainly nonempty.

**Proposition 4.** Fix an identification $\mathbb{S}^1 \cong (\bar{M}_1(\mathbb{R}^2))$ with the moduli space of charge 1 centered monopoles on $\mathbb{R}^2$ and denote $k$ copies of this by $\mathbb{T}^k$. Then, for all $[m] \in H^0(\Sigma, \mathbb{R})/\mathbb{R}$, there is $\mu_0 > 0$, such that for $m_0(m) > \mu_0$ there is a function

$$H : X^k(m) \times H^0(\Sigma, \mathbb{S}^1)/\mathbb{S}^1 \times H^1(X, \mathbb{S}^1) \times \mathbb{T}^k \to C_{k,m}(X, g),$$

with the property that for each configuration $(A_0, \Phi_0) = H(p, [c], \alpha, \theta)$ there are real numbers $\epsilon^i_{\text{out}} = 2\epsilon^i_{\text{in}} = O(m_0^{-1/2})$ and $\lambda_i = O(m_0)$ such that

- $(A_0, \Phi_0)$ is a configuration on a $SU(2)$ bundle $E$, such that $E|_{X \setminus \cup_{i=1}^k B_{\epsilon^i_{\text{out}}}(p_i)} \cong L \oplus L^{-1}$, where $L \oplus L^{-1}$ is the bundle from theorem\[2\]
- On $X \setminus \cup_{i=1}^k B_{\epsilon^i_{\text{out}}}(p_i)$, the configuration $(A_0, \Phi_0)$ coincides with a Dirac monopole,
Using geodesic normal coordinates on each $B_{\epsilon_i}(p_i)$, $(A_0, \Phi_0)$ coincides with a centered charge 1 and mass $\lambda_i$ BPS monopole on $\mathbb{R}^3$.

Proof. Let $x = (p_i, [c], \alpha, \theta) \in X^k(m) \times H^0(\Sigma, \mathbb{S})/\mathbb{R} \times H^1(X, \mathbb{S}) \times \mathbb{T}^k$. Starting with $(p_i, [c], \alpha)$, theorem 3 in the last section constructs a reducible $SU(2)$ Dirac monopole $(A_D, \Phi_D)$ on $L \oplus L^{-1}$ over $X \setminus \{p_1, \ldots, p_k\}$. From the proof of lemma 7 in a neighborhood of each $p_i$, one can write

$$\phi_D = -\frac{1}{2r} + c_i + m_0 + O(r),$$

where the $c_i$'s are constants independent of the average mass $m_0$ and depend only on the points $p_i$ and the class $[m]$. Moreover there is $\mu > 0$, such that for $m_0 > \max \{1 + 2 \sup_i |c_i|, \mu\}$ and define

$$(2.7) \quad \lambda_i = m_0 + c_i$$

$$(2.8) \quad \epsilon_{\epsilon_i} = \lambda_i^{-1/2},$$

and one can check that locally around each $p_i$ for $r > \epsilon_{\epsilon_i}$, it holds that $\phi_D > \frac{1}{2} r$.

The identification $\mathbb{S}^1 \cong M_1([\mathbb{R}^3])$ gives for each element of $\theta_i \in \mathbb{S}^1$ a framed centered BPS monopole $(A_{BPS}^{\theta_i}, \Phi_{BPS}^{\theta_i}, \eta_i)$. As the bundle $L$ has degree one on small spheres around each $p_i$ we can use the framing $\eta_i$ to identify the trivial $C^2$ bundle over $\partial B_{\epsilon_i} \setminus \{p_i\}$ with the restriction of $L \oplus L^{-1}$. This extends the bundle $L \oplus L^{-1}$ over the points $p_i$ to form the bundle $E$.

Recall from definition 2 that $|\Phi_{BPS}^{\theta_i}| \geq \frac{1}{2} c^0$ outside $B_1(0) \subset \mathbb{R}^3$. After scaling these BPS configurations to have mass $\lambda_i$, they satisfy $|\Phi_{BPS}^{\lambda_i}| \geq \frac{1}{2} c^0$ outside the ball of radius $\lambda^{-1}_i$ in $\mathbb{R}^3$. Let $\epsilon_{\epsilon_i} = 2(\lambda_i)^{-1/2}$, then $\text{dist}(p_i, p_j) > 2\epsilon_{\epsilon_i}$. Then using geodesic normal coordinates centered at the points $p_i$ and $\theta = (\theta_1, \ldots, \theta_k) \in \mathbb{T}^k$ to identify the bundles we can pullback these scaled monopoles $(A_{BPS}^{\lambda_i}, \Phi_{BPS}^{\lambda_i})$ from a small ball $B_{\epsilon_i} \subset \mathbb{R}^3$ to the ball $B_{\epsilon_i}(p_i)$.

Now consider the open cover of $X$ given by the $B_{\epsilon_i}(p_i)$ and $U_e = X \setminus \cup_{i=1}^k B_{\epsilon_i}(p_i)$ and let $\{\chi_{\epsilon_i}, \chi_1, \ldots, \chi_k\}$ be a partition of unity subordinate to this cover, such that

$$\chi_{\epsilon_i} = \left\{ \begin{array}{ll} 1 & \text{in } B_{\epsilon_i}(p_i), \\ 0 & \text{in } X \setminus B_{\epsilon_i}(p_i). \end{array} \right.$$

and

$$\sum_{i=1}^k |\nabla \chi_{\epsilon_i}| + |\nabla \chi_{\epsilon_i}| \leq c \sup_{i \in \{1, \ldots, k\}} (\epsilon_{\epsilon_i} - \epsilon_{\epsilon_i})^{-1} \leq c \sqrt{m_0}.
$$

Define the approximate solution as the following configuration on $E$

$$(2.9) \quad \Phi_0 = \chi_{\epsilon_i} \phi_D + \sum_{i=1}^k \chi_{\epsilon_i} \Phi_{BPS}^{\lambda_i}$$

$$(2.10) \quad A_0 = A_D + \sum_{i=1}^k \chi_{\epsilon_i} (A_{BPS}^{\lambda_i} - A_D).$$

One must remark that even though the connection $A_D$ does not extend over the points $p_i$, the connection $A_0$ does, as on each trivialization over $B_{\epsilon_i}(p_i)$, the connection $A_0$ is represented by the connection $A_{BPS}^{\lambda_i}$. □
Lemma 8. There is a constant $c > 0$ independent of $m$, such that for any approximate solution $(A_0, \Phi_0)$ in the image of the map $H$ the quantity $e_0 = \ast F_{A_0} - \nabla A_0 \Phi_0$ vanishes outside the balls $B_{\epsilon^i_{\text{out}}}(p_i)$ and its $C^0$ norm is bounded by
\[ |e_0| \leq cm_0. \]

In particular, if the metric $g$ on $X$ is exactly Euclidean on the balls $B_{\epsilon^i_{\text{out}}}(p_i)$, then in fact the error $e_0$ is supported on the annulus $B_{\epsilon^i_{\text{out}}}(p_i) \setminus B_{\epsilon^i_{\text{in}}}(p_i)$.

Proof. On $X \setminus \cup_{i=1}^k B_{\epsilon^i_{\text{out}}}(p_i)$ the configuration $(A_0, \Phi_0)$ agrees with the Dirac monopole $(A_D, \Phi_D)$ and hence satisfies the monopole equations. So, the error term $e_0 = \ast F_{A_0} - \nabla A_0 \Phi_0$ is supported on the small balls $\cup_{i=1}^k B_{\epsilon^i_{\text{out}}}(p_i)$. On each of these balls, say $B_{\epsilon^i_{\text{out}}}(p_i)$ the bundle $E$ has a trivialization and $\chi_{\text{in}} = 1 - \chi_{\text{out}}$, these may be used to write
\[
\Phi_0 = A_{\lambda_i}^{BPS} + \chi_{\text{out}}(\Phi_D - \Phi_{\lambda_i}^{BPS}) \\
A_0 = A_{\lambda_i}^{BPS} + \chi_{\text{out}}(A_D - A_{\lambda_i}^{BPS}).
\]

Since this agrees with $(A_{\lambda_i}^{BPS}, \Phi_{\lambda_i}^{BPS})$ in the ball $B_{\epsilon^i_{\text{in}}}(p_i)$, the error term only depends on how far the metric $g$ on these balls differs from the Euclidean one. Computing the curvature and the covariant derivative of the Higgs field
\[
F_{A_0} = F_{A_{\lambda_i}^{BPS}} + d_{A_{\lambda_i}^{BPS}} \chi_{\text{out}}(A_D - A_{\lambda_i}^{BPS}) + \chi_{\text{out}}^2 [(A_D - A_{\lambda_i}^{BPS}) \wedge (A_D - A_{\lambda_i}^{BPS})]
= F_{A_{\lambda_i}^{BPS}} + d \chi_{\text{out}} \wedge (A_D - A_{\lambda_i}^{BPS}) + \chi_{\text{out}} d_{A_{\lambda_i}^{BPS}} (A_D - A_{\lambda_i}^{BPS}) + \chi_{\text{out}}^2 [(A_D - A_{\lambda_i}^{BPS}) \wedge (A_D - A_{\lambda_i}^{BPS})],
\]
\[
\nabla_{A_0} \Phi_0 = \nabla_{A_{\lambda_i}^{BPS}} \Phi_0 + \chi_{\text{out}} [(A_D - A_{\lambda_i}^{BPS}) \wedge (A_D - A_{\lambda_i}^{BPS})],
= \nabla_{A_{\lambda_i}^{BPS}} \Phi_0^{BPS} + d \chi_{\text{out}} (\Phi_D - \Phi_{\lambda_i}^{BPS}) + \chi_{\text{out}} \nabla_{A_{\lambda_i}^{BPS}} (\Phi_D - \Phi_{\lambda_i}^{BPS}) + \chi_{\text{out}} [(A_D - A_{\lambda_i}^{BPS}) \wedge (A_D - A_{\lambda_i}^{BPS})],
\]
\[
\ast F_{A_0} - \nabla_{A_0} \Phi_0 = \ast F_{A_{\lambda_i}^{BPS}} - \nabla_{A_{\lambda_i}^{BPS}} \Phi_0 + \chi_{\text{out}} \left( \ast d_{A_{\lambda_i}^{BPS}} (A_D - A_{\lambda_i}^{BPS}) - \nabla_{A_{\lambda_i}^{BPS}} (\Phi_D - \Phi_{\lambda_i}^{BPS}) \right) + \ast (d \chi_{\text{out}} \wedge (A_D - A_{\lambda_i}^{BPS})) - d \chi_{\text{out}} (\Phi_D - \Phi_{\lambda_i}^{BPS}) + \chi_{\text{out}}^2 \ast [(A_D - A_{\lambda_i}^{BPS}) \wedge (A_D - A_{\lambda_i}^{BPS})] - \chi_{\text{out}} [(A_D - A_{\lambda_i}^{BPS}) \wedge (A_D - A_{\lambda_i}^{BPS})].
\]

The first of these terms would vanish if the metric $g$ is Euclidean in these balls. The terms $|A_D - A_{\lambda_i}^{BPS}|$ and $|\Phi_D - \Phi_{\lambda_i}^{BPS}|$ always appear multiplied by $\chi_{\text{out}}$ or $d \chi_{\text{out}}$ which are supported outside $B_{\epsilon^i_{\text{in}}}(p_i)$. So, one starts by estimating these on the annulus $B_{\epsilon^i_{\text{out}}}(p_i) \setminus B_{\epsilon^i_{\text{in}}}(p_i)$, where lemma 8 gives
\[
\Phi_D = \Phi_{\lambda_i}^{BPS} + O(\lambda_i e^{-\lambda_i r}), \quad A_D = A_{\lambda_i}^{BPS} + O(\lambda_i r e^{-\lambda_i r}),
\]
and since on these annuli $r \in (\epsilon^i_{\text{in}}, \epsilon^i_{\text{out}})$ and $\lambda_i = O(m_0)$, while $\epsilon^i_{\text{out}} = O(m_0^{-1/2})$
\[
|A_D - A_{\lambda_i}^{BPS}| + |\Phi_D - \Phi_{\lambda_i}^{BPS}| = O(m_0 e^{-\sqrt{m_0}}).
\]
and this gives
\[ | \ast (d\chi_{\text{out}} \wedge (A_D - A_{\text{BPS}})) | + |d\chi_{\text{out}}(\Phi_D - \Phi_{\text{BPS}})| = O(m_0^{3/2} e^{-\sqrt{m_0}}) \]
\[ |\chi_{\text{out}}^2 (A_D - A_{\text{BPS}})| + |\chi_{\text{out}} [(A_D - A_{\text{BPS}})](\Phi_0)| = O(m_0 e^{-\sqrt{m_0}}) \]
\[ \chi_{\text{out}}^2 (| \ast d_{\text{BPS}}(A_D - A_{\text{BPS}})| + |\nabla_{\text{BPS}}(\Phi_D - \Phi_{\text{BPS}})|) = O(m_0 e^{-\sqrt{m_0}}). \]

Back to evaluate the first term \(*F_{A_{\text{BPS}}} - \nabla_{\text{BPS}} \Phi_{\text{BPS}}\), one needs to compare the metric \(g\) with the Euclidean metric \(g_0\) on the balls \(B_{\epsilon_{\text{out}}} (p_i)\). Let the \(\{x_i\}_{i=1,2,3}\) denote geodesic normal coordinates centered at the point \(p_i\) and recall that these are used to pullback the configuration \((A_{\text{BPS}}, \Phi_{\text{BPS}})\) from \(\mathbb{R}^3\) to this small ball. In these coordinates \(g = g_0 + x_i x_j \gamma_{ij} + O(x^3)\) for some symmetric 2-tensor \(\gamma = x_i x_j \gamma_{ij}\). After a short computation expanding the formula \(\omega \wedge \ast \omega = |\omega|^2 dvol_g\) for any \(k\)-form \(\omega\), one concludes that
\[ \ast_g \omega = \left(1 + \frac{\gamma(\omega, \omega)}{|\omega|^2_{g_0}} - \frac{1}{6} \text{Ric}^{ij} x_i x_j \right) \ast_0 \omega + O(x^3). \]

Applying this to \(*F_{A_{\text{BPS}}}\) gives
\[ *F_{A_{\text{BPS}}} - \nabla_{\text{BPS}} \Phi_{\text{BPS}} = *_0 F_{A_{\text{BPS}}} - \nabla_{\text{BPS}} \Phi_{\text{BPS}} + \]
\[ + \left(\frac{\gamma(F_{A_{\text{BPS}}}, F_{A_{\text{BPS}}})}{|F_{A_{\text{BPS}}}|^2_{g_0}} - \frac{1}{6} \text{Ric}^{ij} x_i x_j \right) *_0 F_{A_{\text{BPS}}}, \]
the first term vanishes because \((A_{\text{BPS}}, \Phi_{\text{BPS}})\) is a monopole for the metric \(g_0\). Regarding the second term it is \(O((\epsilon_{\text{out}})^2 |F_{A_{\text{BPS}}}|_{g_0})\), then since \(\epsilon_{\text{out}} = O(m_0^{-1/2})\) and \(|F_{A_{\text{BPS}}}|_{g_0} = O(m_0^2)\), which gives
\[ | \ast F_{A_{\text{BPS}}} - \nabla_{\text{BPS}} \Phi_{\text{BPS}}|_g = O(m_0). \]

Summing all these terms for big \(m_0\) (all the previous ones were lower order compared to this one), gives the result in the statement. \(\square\)

This lemma points out one other "problem", there is no hope in controlling the error term in the \(C^0\) norm provided by the metric \(g\). This is related to the fact that there is no mass independent lower bound on the first eigenvalue of \(d_2 d_2^*\) for the large mass BPS monopole. The idea to overcome this issue is to rescale all data inside the balls \(B_{\epsilon_{\text{out}}} (p_i)\) and work there with the metric \(g_{m_0^{-1}} = m_0^2 \exp^* \ast g_{m_0^{-1}} g\). Then one can use the scaling identity
\[ (2.11) \quad | \ast F_{A_{\text{BPS}}} - \nabla_{\text{BPS}} \Phi_{\text{BPS}}|_g = \epsilon^2 | \ast F_{A_{\text{BPS}}} - \nabla_{\text{BPS}} \Phi_{\text{BPS}}|_g, \]
for all \(\epsilon > 0\). Applying this with \(\epsilon = m_0^{-1}\) gives the following result

**Corollary 4.** There is \(c \in \mathbb{R}^+\), such that \(e_0 = *F_{A_{\text{BPS}}} - \nabla_{A_{\text{BPS}}} \Phi_{\text{BPS}}\) vanishes on \(X \setminus \cup_{i=1}^k B_{\epsilon_{\text{out}}} (p_i)\) and one the interior of these balls
\[ |(e_0)|_{m_0^{-1}} = m_0^{-2} |e_0|_g \leq cm_0^{-1}. \]

Based on this, one can define function spaces where not only the error term will be small but the first eigenvalue of \(d_2 d_2^*\) is bounded from below.
3 Proof of the Main Theorem

Our goal is to apply a version of the Banach space Implicit Function theorem to solve the monopole equation. In order to do that we divide our proof into 3 major steps: 1. In subsection 3.1 we introduce suitable function spaces. 2. In subsection 3.2 we prove that using these function spaces the linearisation of the monopole equation $d_2$ is surjective. 3. Finally in subsection 3.3 we use the result from the second step in order to find a solution to the monopole equation. This also requires the spaces defined in the first step to give the initial approximate solution a small error term. In fact, we shall be able to control the error term in the approximate solutions in a uniform manner with respect to the mass of the approximate solution.

3.1 Function Spaces

This section introduces function spaces specially adapted to solve the monopole equation. To proceed with the definition of these Function spaces some preparation is needed. Let $(A_0, \Phi_0)$ be the approximate solution constructed in section 2.1. Then on $U = X \setminus \bigcup_{i=1}^k B_{r_{\text{out}}}(p_i)$ the adjoint bundle $\mathfrak{g}_E$ splits as $\mathfrak{g}_E = \mathbb{R} \oplus L^2$ and one writes a section $f = f^\parallel \oplus f^\perp$ according to this splitting. Let $\beta \in \mathbb{R}$ and $K \subset X$ containing $\bigcup_{i=1}^k B_1(p_i)$ and for each $n \in \mathbb{N}_0$, define $W_n : X \to \mathbb{R}$ to be smooth weight functions, interpolating between the values

$$W_n = \begin{cases} \ m_{0-2+n}^{-}, & \text{in } \bigcup_{i=1}^k B_{r_{\text{out}}}(p_i), \\ \ \rho^{-\beta-\frac{2}{2}}, & \text{in } X \setminus K, \end{cases}$$

Define for smooth compactly supported $f$, the norms

$$\|f\|_{0, \beta}^2 = \sum_{i=1}^k \int_{B_1(p_i)} |W_0 f|^2_g \text{dvol}_g$$

$$+ \int_{X \setminus \bigcup_{i=1}^k B_1(p_i)} \left( |W_0 f|^2_g + |f |^2_g \right) \text{dvol}_g.$$  \hspace{1cm} \text{(3.1)}

$$\|f\|_{n, \beta}^2 = \sum_{j=0}^n \sum_{i=1}^k \int_{B_1(p_i)} |W_j \nabla_{A_0}^j f|^2_g \text{dvol}_g$$

$$+ \sum_{j=0}^n \int_{X \setminus \bigcup_{i=1}^k B_1(p_i)} \left( |W_j \nabla_{A_0}^j f|^2_g + \lvert \partial d_{\Phi_0} \left( \nabla_{A_0}^j f^\perp \right) \rvert^2_g \right) \text{dvol}_g.$$ \hspace{1cm} \text{(3.2)}

**Definition 6.** For $n \in \mathbb{N}_0$ and $\beta \in \mathbb{R}$, let $H_{n, \beta}$ be the Hilbert space completion of $C_0^\infty (X, (\Lambda^0 \oplus \Lambda^1) \otimes \mathfrak{g}_E)$ in the inner product obtained from polarizing the norms 3.1 and 3.2.

**Remark 6.** 1. Recall the error $e_0$ of $(A_0, \Phi_0)$ is supported in the small balls $B_{r_{\text{out}}}(p_i)$ and to make it small in the $C^0$ norm we used an $\epsilon = m_{0-1}$-rescaled norm $g_{\epsilon} = \exp^\epsilon g$, i.e. for $f \in \Gamma (X, \Lambda^l \otimes \mathfrak{g}_E)$ one needed to use $|f_{\epsilon}|_{g_{\epsilon}} = \epsilon^2 |f|_g$, where $f_{\epsilon} = \exp^\epsilon f$ if $l = 1$ and $f_{\epsilon} = \epsilon \exp^\epsilon f$ if $l = 0$. Indeed, the functions $W_n$ are defined so that $W_0 = m_{0-2}$, on $\bigcup_{i=1}^k B_{r_{\text{out}}}(p_i)$.

2. Outside a big compact set $K$ the function spaces to be defined will coincide with the usual $L^2$ spaces for the $f^\perp$ component and the Lockhart-McOwen weighted spaces in the $f^\parallel$ component. These are suitable to order to find a bounded right inverse to the operator $d_2$. 

16
The second item follows from the fact that
\[ (3.3) \]

\[ \text{Proof.} \]
\[ \text{inverse for some } \]
\[ \text{following statements hold.} \]

\[ \text{Lemma 9. Let } (X^3, g) \text{ be AC and denote by } g_\Sigma \text{ the metric on the link } \Sigma \text{ at the conical end of } X, \text{ then the following statements hold.} \]

1. There is a discrete set

\[ D(d + d^*) = \{ \beta \in \mathbb{R} \mid (\beta + 1)(3 - 1 + \beta) \in \text{Spec}(\Sigma)_0 \}, \]

such that if \( \beta \in \mathbb{R} \setminus D(d + d^*) \) the operator \[ d^* \] on 1-forms is Fredholm. Here \text{Spec}(\Sigma)_0 denotes the spectrum of the Laplacian \( \Delta_{g_\Sigma} \) on functions.

2. For \( \beta \leq -\frac{1}{2} \), \( \ker(d + d^*)_\beta = \ker(\Delta)_\beta \) and for 1-forms, there is an isomorphism \( \ker(\Delta)_{-\frac{3}{2}} \cong H^1_\Sigma(X, \mathbb{R}) \cong H^2(X, \mathbb{R})^* \).

\[ \text{Proof.} \]
The first item see from [9], chapter 6. The weights appearing in \( D(d + d^*) \) correspond to the rates of the homogeneous closed and coclosed 1-forms on the metric cone \((\mathbb{R}^+ \times \Sigma, g_C = dr^2 + r^2 g_\Sigma)\). The second item follows from the fact that \( L^2_{0,-3/2} = L^2 \) and the statement that there is an isomorphism between the space of \( L^2 \) harmonic 1-forms and the compactly supported cohomology, see [8].

\[ \square \]

\[ \text{Corollary 5. Let } (X^3, g) \text{ be AC with } b^2(X) = 0, \text{ then there is a constant } c > 0 \text{ such that for } \alpha < -1 \text{ and all } u \in L^1_{1,\alpha} \]

\[ \| (d + d^*)u \|_{L^2_{0,\alpha-1}} \geq c \| u \|_{L^1_{1,\alpha}}. \]

\[ \text{Proof.} \]
It follows from the fact that \( d + d^* \) is Fredholm for those \( \alpha \notin D(d + d^*) \), that \( L^2_{0,\alpha-1} = (d + d^*)(L^1_{1,\alpha}) \oplus W_{\alpha-1} \), with \( W_{\alpha-1} \cong \ker(d + d^*)_{-2-\alpha} \). Since \( d + d^* \) has closed image for \( \alpha \notin D(d + d^*) \), there is \( c > 0 \) such that

\[ \| (d + d^*)u \|_{L^2_{0,\alpha-1}} \geq c \| u \|_{L^1_{1,\alpha}}, \]

for all \( u \in \ker(d + d^*)_{\frac{1}{2}} \). Moreover, for \( \alpha \leq -\frac{3}{2} + 1 \), we can integrate by parts and so \( \ker(\Delta)_\alpha = \ker(d + d^*)_\alpha \). This together with the second item in lemma [9] gives \( \ker(d + d^*)_{\alpha} \subset \ker(\Delta)_{-\frac{3}{2}} \cong H^2(X, \mathbb{R})^* \), for all \( \alpha \leq -\frac{3}{2} \). Then, the assumption that \( b^2(X) = 0 \) finally gives \( \ker(d + d^*)_{\alpha} = 0 \) for all \( \alpha \leq -\frac{3}{2} \). However, as the the Laplacian \( \Delta_{g_\Sigma} \) has no negative eigenvalues, the first item in lemma [9] gives that there are no critical rates \( \alpha \) in the interval \((-2, -1)\). Hence, one can increase \( \alpha \) up until (but excluding) \(-1\).
3.2 The Linear Equation

The goal of this section is to solve the linear equation associated with the linearized monopole equation. Namely, one needs to find a range for \( \beta \in \mathbb{R} \) such that if \( g \in H_{\beta-1} \), then one can solve

\[
d_2 f = g
\]

for \( f \in H_{1,\beta} \). In other words one needs to construct a right inverse \( Q \) to the operator \( d_2 : H_{1,\beta} \rightarrow H_{\beta-1} \).

This whole section is occupied with the proof of

**Proposition 5.** Let \( (X, g) \) be asymptotically conical with \( b^2(X) = 0 \). Then there is \( \mu > 0 \), such that if \( m_0(m) > \mu \), the operator

\[
d_2 : H_{1,\beta} \rightarrow H_{0,\beta-1},
\]

associated with any approximate solution \( (A_0, \Phi_0) \) constructed in proposition 2.7, is surjective for all \( \beta > -1 \). In particular, there is a uniformly bounded right inverse \( Q : H_{\beta-1} \rightarrow H_{1,\beta} \).

To prove this proposition we need to show that the cokernel of \( d_2 \) in \( H_{0,\beta-1} \) vanishes. Using the \( L^2 \) inner product one can identify \( H_{\beta-1}^* \cong H_{0,-\beta-2} \) and the cokernel of \( d_2 \) in \( H_{0,\beta-1} \) with the kernel of \( d_2^* \) in \( H_{0,-\beta-2} \). The goal is to find a range of \( \beta \) for which this vanishes. To prove this it enough to prove an inequality of the form

\[
\|d_2^*(f)\|_{H_{0,\alpha-1}} \geq c\|f\|_{H_{0,\alpha}},
\]

for some \( \alpha \in \mathbb{R}, c > 0 \) and all \( f \in H_{1,\alpha} \). Then, we set \( \beta = -\alpha - 2 \) and construct \( Q : H_{0,\beta-1} \rightarrow H_{1,\beta} \) to be such that \( u = Qf \) is the unique solution of \( d_2 u = f \) such that \( u \) is \( H_{1,\beta} \)-orthogonal to the kernel of \( d_2 \) in \( H_{1,\beta} \). To proceed with the proof, let \( \chi \) be a bump function such that

\[
\chi = \begin{cases} 
0 & \text{in } \bigcup_{i=1}^{k} B_{\epsilon_{in}}(p_i), \\
1 & \text{in } U = X \setminus \bigcup_{i=1}^{k} \overline{B_{\epsilon_{out}}(p_i)},
\end{cases}
\]

and vanishing with all derivatives on \( \partial B_{\epsilon_{in}}(p_i) \). One can further suppose that there is a constant \( C > 0 \), such that \( |d\chi|_g \leq C m_0^{1/2} \) on each annulus where \( d\chi \) is supported. Hence its \( L^2 \) norm is bounded by \( \|d\chi\|_{L^2} \leq C m_0^{-1/2} \), as the volume of the set containing the support of \( d\chi \) is of order \( (\epsilon_{out})^3 \cong O(m_0^{-3/2}) \). Then, for any section \( f \in \Omega^1(X, g_P) \) one can write \( f = (1-\chi)f + \chi f \), where the first term is supported inside the balls \( B_{\epsilon_{out}}(p_i) \) and the second one is supported on \( U \), the complement to their closure.

**Lemma 10.** There is \( \mu > 0 \) such that if \( m_0(m) > \mu \) and \( \alpha < -1 \), there is a constant \( c > 0 \), such that

\[
\|d_2^*(\chi f)\|_{H_{0,\alpha-1}} \geq c\|\chi f\|_{H_{0,\alpha}},
\]

for all \( f \in H_{1,\alpha} \).

**Proof.** Recall that in the complement \( U \), the approximate solution \( (A_0, \Phi_0) \) gives a splitting \( g_P \cong \mathbb{R} \oplus L^2 \), which is preserved by the operator \( d_2 \). Moreover, this is an orthogonal decomposition with respect to the \( Ad \)-invariant metric on \( g_P \). So

\[
\|d_2^*(\chi f)\|_{H_{0,\alpha-1}}^2 = \|d_2^*(\chi f)\|_{H_{0,\alpha-1}}^2 + \|d_2^*(\chi f^\perp)\|_{H_{0,\alpha-1}}^2,
\]

and it is enough to separately prove the inequality for each of these terms.
1. The longitudinal component $\chi f^\parallel$ is a one form, so $\|\chi f^\parallel\|_{H_{0,\alpha}} = \|\chi f^\parallel\|_{L^2_{n,\beta}}$ and

$$d_2^\parallel(\chi f^\parallel) = (\ast d(\chi f^\parallel), -d^\ast(\chi f^\parallel)).$$

Then using corollary 5 guarantees that $\|d_2^\parallel(\chi f^\parallel)\|^2_{H_{0,\alpha-1}} \geq c \|\chi f^\parallel\|^2_{H_{1,\alpha}}$, for all $\alpha < -1$ and some $c$ not depending of $f$.

2. For the transverse component $\chi f^\perp$, $\|\chi f^\perp\|_{H_{0,\alpha}} = \|\chi f^\perp\|_{L^2}$ for all $\alpha \in \mathbb{R}$. So we need to consider

$$(3.5) \quad d_2^\perp(\chi f^\perp) = \left(\ast d_{A_0}(\chi f^\perp) + [\chi f^\perp, \partial_\alpha], -\nabla_{A_0} \chi f^\perp\right),$$

in usual $L^2$ spaces. Notice that $\chi f^\perp$ is supported in $U$, where the approximate solution $(A_0, \Phi_0)$ coincides with the Dirac monopole $(A_D, \Phi_D)$. This is by construction such that $\Phi_D = \Phi_D \oplus 0$, using the decomposition $g_{P} = \mathbb{R} \oplus L^2$. Then, integrating by parts together with the Weitzenbök formula [4] gives

$$\|d_2^\perp(\chi f^\perp)\|^2_{L^2} = \langle \chi f^\perp, \partial_{\alpha} \rangle_{L^2}$$

Recall, from lemma 7 that, $\phi_D$ is harmonic on $U$ and is bounded from below by its values at $\partial U$, these being greater or equal to $\frac{m_0}{2}$. Then, $\phi_D \geq \frac{m_0}{2}$ on $U$ and

$$\|d_2^\perp(\chi f^\perp)\|^2_{L^2} \geq \|\nabla D(\chi f^\perp)\|^2_{L^2} + \left(\frac{m_0^2}{4} - \sup_X |Ric|\right) \|\chi f^\perp\|^2_{L^2}$$

$$\geq \|\nabla D(\chi f^\perp)\|^2_{L^2} + \frac{m_0^2}{4} - \sup_X |Ric| \|\chi f^\perp\|^2_{L^2}$$

$$\geq c_2 \|\chi f^\perp\|_{H_{1,\alpha}}$$

for any $\alpha \in \mathbb{R}$ and one can take $c_2 = \min \left\{1, \frac{m_0^2}{4\max_Z(m_i)}\right\} > 0$ for $m_0 > 2\sqrt{\|Ric\|_{L^\infty}}$.

Sum these two inequalities to get

$$\|d_2(\chi f)\|_{H_{0,\alpha-1}} \geq c \|\chi f\|_{H_{1,\alpha}},$$

with $c = \min\{c_1, c_2\}$. For the two inequalities to be true and the statement to hold one needs $\alpha < -1$ due to the component $\chi f^\parallel$, and $m_0 > \mu > 2\sqrt{\|Ric\|_{L^\infty}}$ for the component $\chi f^\perp$.

We shall now use lemma 10 to prove the inequality 3.4. This is done as follows. One minimizes the functional

$$J(f) = \|d_2^\parallel f\|^2_{H_{0,\alpha-1}},$$

subject to the constraint that $\|f\|_{H_{0,\alpha}} = 1$. The minimizer $f$ satisfies an elliptic equation of the kind

$$d_2 d_2^\parallel f + g_1 d_2^\parallel f + g_2 f = 0,$$

where $g_1, g_2$ are smooth functions. A standard iteration argument in elliptic PDE theory can then be used to obtain an $L^\infty$ bound on the minimizer $f$, over compact sets. So that one can write $\|f\|_{L^\infty(K)} < C$, for
$C > 0$ some constant and $K$ some compact set containing $\bigcup_{i=1}^k B_{i_{out}}(p_i)$. Denote by $\sigma d_2^*$ the symbol of the operator $d_2^*$, then

$$\|d_2^*(\chi f)\|_{0,H_{\alpha-1}}^2 = \|\sigma d_2^*(d\chi) f + \chi d_2^* f\|_{H_{0,\alpha-1}}^2 \leq \|\sigma d_2^*(d\chi) f\|_{H_{0,\alpha-1}}^2 + \|\chi d_2^* f\|_{H_{0,\alpha-1}}^2 \leq C_2 \|d\chi\|_{H_{0,\alpha-1}}^2 + \|d_2^* f\|_{H_{0,\alpha-1}}^2,$$

where in the first term one used the bound $\|f\|_{L^\infty} < C$ on $f$ and $C_2 > 0$ denotes some possibly larger constant in order to also bound $|\sigma d_2|$.

In the last term it was used that $\|\chi d_2^* f\|_{H_{0,\alpha-1}}^2 \leq \|d_2^* f\|_{H_{0,\alpha-1}}^2$. Now notice that $|d\chi|$ is supported on the union of the annuli $B_{\varepsilon_{out}}(p_i) \setminus B_{\varepsilon_{in}}(p_i)$, where $|d\chi| \leq C m_0^{1/2}$. However, in this region the spaces $H_{0,\alpha-1}$ use the rescaled norm $\|(d\chi) m_{-1}\|_{g_{m_{-1}}} \leq C m_0^{-3/2}$, see equation \ref{eq:3.1} and the definitions preceding it. Moreover, having into account the volume of the annuli one obtains $\|d\chi\|_{H_{0,\alpha-1}}^2 \leq C m_0^{-3}$, so that

$$\|d_2^* f\|_{H_{0,\alpha-1}}^2 \geq \|d_2^*(\chi f)\|_{H_{0,\alpha-1}}^2 - C_3 m_0^{-3},$$

for some $C_3 > 0$. Insert here the intermediate inequality from proposition \ref{prop:10}

$$\|d_2^* f\|_{H_{\alpha-1}}^2 \geq c \|\chi f\|_{H_{1,\alpha}}^2 - C_3 m_0^{-3} \geq c \|f\|_{H_{0,\alpha}}^2 - c \sum_{i=1}^k \|f\|_{H_{0,\alpha}(B_{\varepsilon_{out}}(p_i))}^2 - C_3 m_0^{-3}.$$

The first term is $c$ as $f$ satisfies the constraint that $\|f\|_{H_{0,\alpha}} = 1$. The last two ones can be made arbitrarily small using the $L^\infty$ bound on $f$ over compact sets and by letting $m_0$ get big. Hence one obtains the inequality in equation \ref{eq:3.4}, then the discussion above it proves the main proposition \ref{prop:5} of this section.

### 3.3 The Nonlinear Terms

Equipped with the surjectivity of the operator $d_2$, proved in proposition \ref{prop:5}, we will now apply the Implicit Function Theorem to solve the monopole equation $\star F_{A_{0+a}} - \nabla A_{0+a} (\Phi_0 + \phi) = 0$. This can be written in the form

$$e_0 + d_2 (a, \phi) + N((a, \phi), (a, \phi)) = 0,$$

where $e_0$ is the error term of the approximate solution $(A_0, \Phi_0)$, $d_2$ the linearisation of the monopole equation at $(A_0, \Phi_0)$ and $N$ is the nonlinear term $N((a, \phi), (b, \psi)) = \star \frac{1}{2} [a \wedge b] - \frac{1}{2} [a, \psi] - \frac{1}{2} [b, \phi]$. We shall look for a solutions $(a, \phi)$ in the image of the right inverse to $d_2$, i.e. $(a, \phi) = Qu$ for some $u$ a 1 form with values in $\mathfrak{g}_P$, such that $u \in H_{0,\beta-1}$, with $\beta > -1$. Then, the equation is

$$u + N(Qu, Qu) = -e_0,$$

which is solved using the following particular version of the contraction mapping theorem.

**Lemma 11.** Let $B$ be a Banach space and $q : B \to B$ a smooth map such that for all $u, v \in B$

$$\|q(u) - q(v)\| \leq k (\|u\| + \|v\|) \|u - v\|,$$

where $k > 0$. Then $q$ has a unique fixed point $u_0 \in B$. Moreover, the error $e = u_0 - u$ satisfies $\|e\| \leq m \|u\|$, for some $m > 0$.
for some fixed constant $k$ (i.e. independent of $u$ and $v$). Then, if $\|v\| \leq \frac{1}{10k}$ there is a unique solution $u$ to the equation

$$u + q(u) = v,$$

which satisfies the bound $\|u\| \leq 2\|v\|.$

In this lemma one interprets $\Sigma$ as a fixed point equation contraction mapping principle applies and one obtains the estimate by keeping track of the norms in the iterations, see [6]. This will be used to prove

**Proposition 6.** Let $k \in \mathbb{N}$ and $(X, g)$ be asymptotically conical with $b^2(X) = 0$. Then, there is $\mu > 0$, such that for all $m \in H^0(\Sigma, \mathbb{R})$ with $m \geq \mu$ and $(p, \alpha, \theta) \in X^k(m) \times H^1(X, S^1) \times \mathbb{T}$. There is a unique charge $k$ and mass $m$ monopole $(A, \Phi)$, which can be written as $(A, \Phi) = (A_0, \Phi_0) + Qu$ and satisfies

$$\|(A, \Phi) - (A_0, \Phi_0)\|_{H_{1,\beta}} \leq Cm^{-\frac{7}{2}},$$

where $(A_0, \Phi_0) = H(p, \alpha, \theta)$ is the approximate solution from proposition [2] and $C$ denotes a constant independent of $m$.

**Lemma 12.** Let $\beta = -1/2 \notin D(d + d^*)$. Then, there is $C > 0$, such that for all $f, g \in H_{1,\beta}$

$$\|N(f, g)\|_{H_{0,\beta-1}} \leq C\|f\|_{H_{1,\beta}}\|g\|_{H_{1,\beta}}.$$

**Proof.** That $\beta = -\frac{1}{2} \notin D(d + d^*)$ follows from the first item in lemma [2] and the fact that the Laplacian $\Delta_\Sigma$ has positive eigenvalues. To prove the inequality, let $\chi$ be the bump function [5,2] from last section and write $N(f, g)$ as the sum of two components, one supported inside the balls $B_i(p_i)$ and the other one outside these. We shall prove the inequality separately for each of these two components.

1. If $f, g$ are supported inside the ball $B^\epsilon_{\text{out}}(p_i)$, then using both the Holdër and Sobolev inequalities

$$\|N(f, g)\|_{H_{0,\beta-1}} = \|m_0^{-2}fg\|_{L^2(B_i(p_i))} \leq C\|m_0^{-2}f\|_{L^4(B_i(p_i))}\|m_0^{-2}g\|_{L^4(B_i(p_i))} \leq C\|f\|_{H_{1,\beta}}\|g\|_{H_{1,\beta}}.$$  

Moreover the constant $C'' > 0$ is independent of $m_0$.

2. For $f, g$ supported on the big open set $U = X \setminus \bigcup_{i=1}^k \overline{B_i(p_i)}$, we can write $f = f^\| + f^\perp$, and similarly for $g$. Then

$$N(f, g) = \left(N(f^\|, g^\|) + N(f^\perp, g^\perp)\right) + N(f^\perp, f^\perp),$$

where the first two terms have values in $g_{\perp}^\|$, while the third has values in $g_{\perp}^\perp$. We shall now bound these separately. For $\beta \leq -\frac{1}{2}$ the Holdër and Sobolev inequalities give

$$\|N(f^\perp, g^\perp)\|_{H_{0,\beta-1}} \leq C\|\phi D N(f^\perp, g^\perp)\|_{L^2} \leq C\|\rho^{\frac{3}{2} - \beta} f^\perp + \frac{1}{2} g^\perp\|_{L^2} \leq C'\|\phi D f^\perp\|_{L^3}\|\rho^{-\frac{3}{2} - \beta} g^\perp\|_{L^6} \leq C\|\phi D f^\perp\|_{L^2}\|g^\perp\|_{L^6_{1,\beta}} \leq C''\|\phi D f^\perp\|_{L^2}\|g^\perp\|_{L^6_{1,\beta}},$$

21
where it was used that \( \beta + \frac{3}{2} - 1 = \beta + \frac{1}{2} \leq 0 \), for \( \beta \leq -\frac{1}{2} \) and that \( \|g\|_{L^6_{0,\beta}} = \|\rho^{1-\frac{3}{2}}g\|_{L^6} \), by definition. Since the weighted \( H \)-norm uses standard \( L^2_k \) spaces along the components in \( g_\beta \) and weighted norms along the \( g_\beta \), one can bound the last item above as

\[
\|N(f^+, g^+\|_{H_{0,\beta-1}} \leq C^\prime \|f^+, g\|_{H_{1,\beta}} \|g\|_{H_{1,\beta}}.
\]

The term \( N(f, g^+) \) follows by a similar computation. To evaluate the other term, which lies in \( g^\perp \), note that for \( \beta \geq -\frac{1}{2} \)

\[
\|N(f^+, g^-)\|_{H_{0,\beta-1}} \leq C\|\rho^{-\beta-1} - \frac{3}{2} N(f^+, g^-)\|_{L^2}
\leq C\|N(f^+, g^-)\|_{L^2},
\]

hence one can once again use the Hölder and Sobolev inequalities to bound the above quantity by

\[
\frac{1}{m_0} \|\phi_D f^\perp\|_{L^2} \|\phi_D g^\perp\|_{L^2} \leq C\|f\|_{H_{1,\beta}} \|g\|_{H_{1,\beta}}, \text{ for } m_0 > \sqrt{C}.
\]

\( \blacksquare \)

Proof. (of proposition \( \ref{prop:uniqueness} \)) We start by showing that \( q(u) = N(Qu, Qu) \) satisfies the hypothesis stated in lemma \( \ref{lem:existence} \) for \( B = H_{0,\beta-1} \) and \( \beta = -1/2 \). This is done by computing

\[
\|N(Qu, Qu) - N(Qv, Qu)\|_{H_{0,\beta-\frac{3}{4}}} = \|N(Q(u + v), Q(u - v))\|_{H_{0,\beta-\frac{3}{4}}}
\leq C\|Q(u + v)\|_{H_{1,\beta-\frac{1}{2}}} \|Q(u - v)\|_{H_{1,\beta-\frac{1}{2}}}
\leq C\left( \|u\|_{H_{0,\beta-\frac{3}{4}}} + \|v\|_{H_{0,\beta-\frac{3}{4}}} \right) \|u - v\|_{H_{0,\beta-\frac{3}{4}}},
\]

where the constant \( C \) may possibly change from one line to the other. The only hypothesis of lemma \( \ref{lem:existence} \) which remains to be checked is that it is possible to make \( \|e_0\|_{H_{0,\beta-\frac{3}{4}}} \leq \frac{1}{10c} \). This is an immediate consequence of corollary \( \ref{cor:regularity} \). This states the existence of an approximate monopole \( H(p_1, a_1, \theta_1) \), whose error term \( e_0 \) satisfies \( W_0\|e_0\| \leq cm_0^{-1} \), for some constant \( c > 0 \) not depending on \( m_0 \). Moreover, \( |e_0| \) is supported on \( \bigcup_{i=1}^k B_{\delta_{out}}(p_i) \)

\[
\|e_0\|_{H_{0,\beta-\frac{3}{4}}} = \int_X |W_0e_0|^2 \leq ckm_0^{-2}Vol(B_{\delta_{out}(p_i)}) \leq ckm_0^{-7/2}
\]

and so for big \( m_0 \) one obtains a solution \( u \) to equation \( \ref{eq:monopole} \). Moreover, there is a constant \( c' \) such that this is the unique solution which satisfies \( \|u\|_{H_{0,\beta-\frac{3}{4}}} \leq c'm_0^{-7/4} \). Then by setting \( (A, \Phi) = (A_0 + a, \Phi_0 + \phi) \), where \( (a, \phi) = Qu \), one obtains a monopole which is the unique one of this form satisfying

\[
\| (A, \Phi) - (A_0, \Phi_0) \|_{H_{1,\beta-\frac{1}{2}}} \leq Cm_0^{-7/4}.
\]

\( \blacksquare \)

### 4 Uniqueness in a Gauge Orbit

Proposition \( \ref{prop:uniqueness} \) can be used to make the following
Definition 7. Let \( k \in \mathbb{N} \) and \((X, g)\) be asymptotically conical with \( b^2(X) = 0 \) and \( m \in H^0(\Sigma, \mathbb{R}) \cong \mathbb{R} \), be such that \( m \geq \mu \), so that proposition 6 applies and defines a map

\[
\tilde{h} : X^k(m) \times H^1(X, \mathbb{S}^1) \times \mathbb{T}^k \rightarrow M_{k,m}.
\]

The image of the map \( \tilde{h} \) above corresponds to monopoles \((A, \Phi)\), which can be written as \((A_0, \Phi_0) + Qu\), where \( \|Qu\|_{H_{1,-1/2}} \leq Cm^{-7/4} \) and \((A_0, \Phi_0)\) is an approximate solution in the image of the map \( H \) from proposition 4. The goal of this section is to show that given \((A, \Phi)\) in the image of \( \tilde{h} \), all gauge equivalence classes of monopoles close to \((A, \Phi)\) come from this construction, i.e. to show

Theorem 4. The map \( \tilde{h} \) descends to a local diffeomorphism

\[
h : X^k(m) \times H^1(X, \mathbb{S}^1) \times \mathbb{T}^k \rightarrow M_{k,m}.
\]

The rest of this section is dedicated to prove this theorem. We shall now introduce some notation, let \( P = X^k(m) \times H^1(X, \mathbb{S}^1) \times \mathbb{T}^k \) denote the parameter space, \( x \in P \) be a point and \((A, \Phi) = \tilde{h}(x)\), then \([A, \Phi] = h(x) \in M_{k,m}\) is the corresponding gauge equivalence class. Moreover, \((A, \Phi) = (A_0, \Phi_0) + Qu\), where \((A_0, \Phi_0) = H(x)\) and \( \|Qu\|_{H_{1,-1/2}} \leq Cm^{-7/4}\).

Invoking the implicit function theorem, we may take a model for \( M_{k,m}\) as a slice in \( C_{k,m}\). This identifies a neighborhood of \( h(x)\) in \( M_{k,m}\), with a neighborhood of zero in \( \ker(d_1^* + d_2)_-1/2 \subset T_{h(x)}C_{k,m}\). Since \( d_1^* + d_2 \) is Fredholm 7, we can fix an orthonormal basis of \( \ker(d_1^* + d_2)_-1/2 \) and define a projection

\[
\pi_h : T_{h(x)}C_{k,m} \rightarrow \ker(d_1^* + d_2)_-1/2.
\]

Then it is enough to show that there are neighborhoods \( U \) of \( x \) in \( P \) and \( V \) of \( 0 \) in \( \ker(d_1^* + d_2)_-1/2\), such that

\[
\pi_h \circ \tilde{h} : U \rightarrow V
\]

is a diffeomorphism.

Lemma 13. There is \( \mu > 0 \) and \( R > 0 \) such that for all \( m \geq \mu \) the map

\[
\pi_h \circ H : P \rightarrow \ker(d_1^* + d_2)_-1/2,
\]

maps an open neighborhood \( U' \) of \( x \) in \( P \) onto \( B_R \) a ball of radius \( R \) in \( \ker(d_1^* + d_2)_-1/2 \subset C_{k,m}\), equipped with the metric \( H_{1,-1/2}\), i.e.

\[
B_R = \{ u \in \ker(d_1^* + d_2)_-1/2 \mid \|u\|_{H_{1,-1/2}} < R \}.\]

Proof. Notice that given \( x \in P \), the map \( dH_x : TP \rightarrow T_{H(x)}C_{k,m} \) is injective and we can define the norm

\[
\|v\|_P = \|dH_x(v)\|_{H_{1,-1/2}}\]

where \( v \in TP \) and \( dH_x(v) = \left. \frac{d}{dt} \right|_{t=0} H(\exp_x tv) \). It follows from 7 that \( d_1^* + d_2 \) has index \( i = 4k+b^1(X) \) and as it is surjective, we have \( \dim(\ker(d_1^* + d_2)) = \dim(T_x P) \) and so in order to show that \( \pi_h \circ H \) is an isomorphism it is enough to show that it is injective. In fact we shall prove an inequality of the form

\[
\|\pi_h \circ dH_x(v) - dH_x(v)\|_{H_{1,\beta}} \leq c(m) \|v\|_P,
\]

where \( \beta \approx \frac{1}{16} \).
with $c(m) > 0$ converging to zero as $m \to +\infty$ and all $v \in T_x P$. To prove this inequality notice that the operator $d_1^* \oplus d_2$ has closed image, $\pi_h(dH_x(v))$ is in its kernel and $\pi_h dH_x(v) - dH_x(v)$ is orthogonal to it. So, there is a constant $c > 0$ such that for all $v$

$$\|d_1^* \oplus d_2 (\pi_h dH_x(v) - dH_x(v))\|_{H_0, \beta - 1} \geq c \|\pi_h dH_x(v) - dH_x(v)\|_{H_1, \beta},$$

and the left hand side is equal to $\|d_1^* \oplus d_2 (\pi_h dH_x(v))\|_{H_0, \beta - 1}$ which by construction of the map $H$ is no greater than $c(m)\|dH_x(v)\|_{H_1, \beta} = c(m)\|x\|_P$, with $c(m) \to 0$ as $m \to +\infty$. Hence, for large enough $m$, the map $\pi_h \circ dH$ is a degree 1 map of a sphere of radius $R_1$ in $T_x P$ into a topological sphere in the annulus of in $\ker(d_1^* \oplus d_2)$ whose inner and outer radius are $R_1 - c(m)$ and $R_1 + c(m)$ respectively. Hence, by the implicit function theorem, for large $m$, $\pi_h \circ H$ is a local diffeomorphism and maps an $m$ independent neighborhood $U'$ of $x$ onto a neighborhood of $H(x)$. Moreover, one can use equation 4.3 to prove that there is an inequality

$$\|\pi_h dH_x(v)\|_{H_1, \beta} \geq (1 - c(m))\|v\|_P$$

and so the derivative $\pi_h \circ dH_x$ is uniformly bounded by below for large $m$. This implies that for large $m$, $\pi_h \circ H(U')$ is a neighborhood of $\pi_h \circ H(x)$ with a fixed size, in particular it contains a ball of a fixed radius $B_R$ around $\pi_h(H(x))$.

Recalling the discussion preceding the statement of the previous lemma, we shall now go on to prove that there are $U$ and $V$ such that

$$\pi_h \circ \tilde h : U \to V$$

is a diffeomorphism. We write $\tilde h(x) = H(x) + Q u$ with $Q u$ given by proposition 6. Hence, it follows from elliptic regularity that we can obtain $H_{k, \frac{1}{2}}$ bounds in on $Q u$ for all $k$. Moreover, these are such that converge to 0 as $m \to \infty$, in particular

$$\|Q u\|_{H_{1, \frac{1}{2}}} \leq C m^{-\frac{2}{7}}.$$  

Hence $\pi_h(\tilde h(x)) = \pi_h(H(x)) + \pi_h(Q u)$ and $\|\pi_h(Q u)\|_{H_{1, \frac{1}{2}}}$ is very small. It follows that the equation $\pi_h(\tilde h(x)) = y$, for $y$ contained in a ball of radius $R' < R$ always has a unique solution provided that $C m^{-\frac{2}{7}} < R - R'$. This can always be achieved by taking $m$ to be large enough, namely

$$m > \mu = \left(\frac{C}{R - R'}\right)^{\frac{7}{4}}.$$  

Hence we can take $V = B_{R'}$ and $U \subset U'$ to be its inverse image via $\pi_h \circ \tilde h$. This finishes the proof of theorem 4.
