Abstract:

Background: Several discriminating techniques have been proposed to discriminate between β-thalassemia trait (βTT) and iron deficiency anemia (IDA) so far. These discrimination techniques are important clinically, but they are challenging and normally difficult; so if a patient with IDA is diagnosed as βTT, then it is deprived of iron therapy. This study is the first application of the Bayesian tree-based method for differential diagnosis of βTT from IDA.

Method: In this study, 907 patients were enrolled with the ages over 18-year-old with microcytic anemia. Bayesian Logit Treed (BLTREED) has been used to discriminate βTT from IDA.

Results: Mean corpuscular volume (MCV) was found as the main predictor in diagnostic discrimination. BLTREED model showed high sensitivity (96%), specificity (93%), accuracy (95%), Youden's index (89), as well as positive and negative predictive values in the differential diagnosis of βTT from IDA. Also, AUC revealed a more precise classification with an area under the curve value of 0.98.

Conclusions: BLTREED model showed excellent diagnostic accuracy for differentiating βTT from IDA. In addition, understanding tree-based methods are easy and need not a statistical experience, so this advantage can help physicians in making the right clinical decision. Thus, we suggest the using of the BLTREED model as a powerful method in data mining techniques in order to develop sensitive and accurate diagnostic methods for discriminating between these two anemia disorders.

Keywords: Bayesian Decision Tree, diagnosis, iron deficiency anemia (IDA), β-thalassemia trait (βTT)
Highlight

1- To the best of our knowledge this study is the first application of Beysian tree-based method for differential diagnosis of βTM from IDA.

2- We propose an automatic detection model of beta-Thalassemia carriers based on a Beysian tree-based method.

3- The proposed model will support medical decisions for differential diagnosis of βTM from IDA to avoid much more expensive, time-consuming laboratory tests especially in countries with limited recourses or poor health services.

1. Introduction:

Iron deficiency anemia (IDA) and β-thalassemia trait (βTT) are the two most common hypochromic microcytic anemia. βTT is more prevalent in the Mediterranean region, in specific geographical areas, including the Caspian Sea and Persian Gulf regions, the 10% prevalence was reported (1). To prevent iron overload and its complications caused by misdiagnosis and inaccurate treatment, and also determining the necessity of prenatal investigations for hemoglobin chain disorders, it is important to differential βTT from IDA (2). Hemoglobin electrophoresis, serum iron and ferritin levels are considered to make a definitive differential diagnosis between βTT and IDA (3-5). However, to reduce costs related to diagnostic workup, various major studies have been conducted to propose appropriate discrimination indices to distinct between βTT and IDA. These indices have been defined to quickly discriminate between IDA and βTT and avoid more time-consuming and expensive methods. Mentzer (6), Shine and Lal (7), England and Fraser (8), RBC (9), Srivastava (10), Ricerca (11), Green and
King (12), Bessman (RDW) (13), Das Gupta (14), Jayabose (RDWI) (15), Telmissani-MCHD (16), Telmissani-MDHL (16), Huber-Herklotz (17), Kerman I (18), Kerman II (18), Sirdah (19), Ehsani (20), Keikhaei (21), Nishad (22), Wongprachum (23), Sehgal (24), Pornprasert (25), Sirachainan (26), Bordbar (27), Matos and Carvalho (28), Janel (11T) (29), CRUISE Index (30), Index26 (30) are hematological discrimination indices used for discriminating between the IDA and βTT. However, these indices obtained empirically and have an inconsistent performance for differential diagnosis of βTT and IDA in the same patient (31). Sometimes the same indices showed different discrimination power in varied age groups (32, 33).

Recently, the accessibility of powerful statistical software has provided the application of data mining techniques for health-related data. Many studies have been proposed to advance statistical methods and data mining techniques such as decision Trees methods (68) for differential diagnostic between βTT and IDA to avoid much more expensive, time-consuming, and complicated laboratory procedures and non-satisfactory hematological indices in discriminating between βTT and IDA (34-37, 39, 69, 70). (34-39). Urrechaga, Aguirre, and Izquierdo (38) used multivariable discriminant analysis for differential diagnosis of microcytic anemia. Wongserree et.al (39) implemented neural network and genetic programming for thalassemia classification. Dogan and Turkoglu (36) proposed a decision tree for detecting iron deficiency anemia from hematology parameters.

Setsirichok (34) evaluated the classification of blood characteristics by a C4.5 decision tree, a naive Bayes classifier and a multilayer perceptron for classifying eighteen classes of thalassemia abnormality. Jahangiri et al. (37) used classic decision-tree-based methods for constructing a differential diagnosis scheme and investigating the performance of several tree-based methods for the differential diagnosis of βTT from
IDA. Decision Trees have advantages over traditional statistical methods like discriminant analysis, generalized linear models (GLMs) and survival analysis. The main advantage of tree-based methods is tree structure that makes it easy to interpret the clinical data and to be accepted by medical researchers and clinicians. But these methods suffer from greediness problem and this problem have disadvantages like: limit the exploration of tree space, dependence future splits to previous splits, generate optimistic error rates and the inability of the search to find a global optimum (71).

Bayesian tree approaches are proposed to solve the greediness problem of tree-based methods. Also, these Bayesian approaches can quantify uncertainty and these approaches explore the tree space more than classic tree approaches. Bayesian approaches combine prior information with observations unlike classic tree methods (these methods use only observations for data analysis). These Bayesian approaches define prior distributions on the components of classic tree methods and then use stochastic search algorithms through Markov chain Monte Carlo (MCMC) algorithms for exploring tree space (72-78). Bayesian tree-based methods have been developed since it can be account more sensibly and comprehensively for uncertainty than frequentist methods.

In this paper, a Bayesian tree-based method was proposed for the differential diagnosis of βTT from IDA based on simple laboratory test results.

2. Material and methods

2.1. Criteria For Selecting patient Groups

In this study, a total of 907 patients aged over 18 years old diagnosed with IDA or βTT were selected to develop new discriminating indices. Hematological parameters like
Hb (Hemoglobin), Mean Corpuscular Volume (MCV), Mean Corpuscular Hemoglobin (MCH), Red Blood Cell Distribution Width (RDW), Mean Corpuscular Hemoglobin Concentration (MCHC), and Red Blood Cell count (RBC) were measured by using Sysmex kx-21 automated hematology analyzer.

2.2. Inclusion criteria:
In the IDA group, patients had hemoglobin (Hb) levels less than 12 and 13 g/dL for women and men, respectively. Mean corpuscular hemoglobin (MCH) and Mean corpuscular volume (MCV) were below 80 fL and 27 pg for both sexes, respectively, and for men, ferritin of <28 ng/mL was considered as IDA. In the βTT group, patients had a MCV value below 80 fL. Patients with HbA2 levels of >3.5% were considered as βTT carriers.

2.3. Exclusion criteria:
For the IDA group, patients who had mutations associated with αTT (3.7, 4.2, 20.5, MED, SEA, THAI, FIL, and Hph) were excluded so, individuals presenting the two diseases simultaneously were not selected. For the βTT group, patients with αTT confirmed by presence of mutations in molecular analysis were excluded. All patients with malignancies or inflammatory/infectious diseases diagnosed based on clinical data and personal information obtained from medical records were also excluded. In addition, pregnant women with severe anemia (Hb < 8 g/dl) and anemia due to chronic disease or other hemoglobinopathies as well as the simultaneous development of IDA and βTT were excluded.

2.4. Ethical consideration
This study was approved and supported by Ethical committee affiliated by the Ahvaz Jundishapur University of Medical Sciences (AJUMS), Ahvaz, Iran.

2.5. Methods

CBC analysis of EDTA-K2 anti-coagulated blood samples was performed using the Sysmex kx-21 automated hematology analyzer (Japan) to measure differential parameters, including Hb, MCV, MCH, and RDW. Also, HbA2 (Hemoglobin A2), Serum Iron, TIBC (Total Iron-Binding Capacity) and Serum Ferritin measured for all patients. The patients with HbA2 > 3.5% diagnosed as βTT, that 537 patients had this condition and 370 patients with serum Iron < 50 µg/dl, TIBC > 450 µg/dl and serum Ferritin < 12 µg/dl diagnosed as IDA. Patients who had conditions of both βTT and IDA groups and or none of the diagnosis conditions of βTT and IDA groups were excluded from the study.

2.6. Statistical Analysis

Decision trees methods are defined as machine-learning methods for constructing prediction models from data and could provide a solution for constructing the diagnostic test (79, 80). These methods are valuable tools in data mining techniques. Tree-based models including nonparametric models and do not need any assumptions about the functional form of the data.

One of the advantages of these methods is the graphical presentation of results that make them easy to interpret and no need for statistical experience for understanding result of models (51, 81-83). Tree-based models also were constructed based on Bayesian algorithms. The Bayesian approach of CART model (BCART) with defining a prior distribution was proposed by Chipman et.al in 1998 (73). Bayesian Logit Treed
(BLTREED) model as an extension of BCART was also developed by Chipman et al. by fitting a logistic regression model for data prediction in the terminal nodes (74, 84).

2.6.1. Bayesian Logit Treed (BLTREED) Model

Bayesian approach (BCART) for CART model was constructed by defining a prior distribution on the pair of components of this model namely \((\theta, T)\); \(T\) is a binary tree with \(K\) terminal nodes or tree with size \(K\) and \(\theta = (\theta_1, \theta_2, \ldots, \theta_K)\) is parameters set in the terminal nodes \((\theta_i = p_{ij}, i=1, \ldots, K; j=1,\ldots, N)\); the number of distinct classes of the response variable and \(p_{ij}\) shows the probability of \(jth\) class of response variable in \(ith\) terminal node. It can be shown that the joint posterior distribution of parameters and tree structure were as following equation

\[
(\theta|T) \ p(T) = p(\theta, T)
\]

Where \(p(T)\) and \(p(\theta|T)\) shows the prior distribution for tree and parameters in terminal nodes respectively. In each Bayesian approach, prior distributions define as unknown, so in this Bayesian approach tree structure and parameters in terminal nodes were considered as unknowns (73). BCART was extended by Chipman et al. (2002, 2003) by fitting a parametric model such as logistic regression model for data prediction and describe the conditional distribution of \(Y|X\) in each terminal nodes (74, 84). In BLTREED model the conditional distribution of \(Y|X\) unlike BCART model depends on \(X (Y|X \sim f(Y|X, \theta_i))\) and also by fitting sophisticated model at terminal nodes (by fitting logistic regression model for data prediction in each terminal nodes), smaller trees and
more interpretable were generated. In BLTREED model, one subset of $X$ can use to
generate the tree and another subset can use for fit models in terminal nodes (these
subsets can be joint and or disjoint). In this Bayesian approach $\theta_i = B_i$ shows the set
of regression coefficients for the logistic model fitted in $i$th terminal node.

The recursive stochastic process using a tree-generating stochastic process for tree
growing ($p(T)$)
is as follow (73, 74):

1- Start from $T$ that has only a root node (terminal node $\eta$).

2- Calculate the probability for splitting node $\eta$ as follow:

$$P_{\text{Split}} = \alpha(1 + d_\eta)^{-\beta}$$

Where, $d_\eta$ is the depth of the node $\eta$, $\alpha$ is the base probability of tree growth
of splitting a node, and $\beta$ is the rate which determine the propensity to split
decreases with increased tree size.

Actually ($\alpha$ & $\beta$) are parameters that control the shape and size of trees and
these parameters provide a penalty to avoid over-fitting model.

3- If the node $\eta$ splits to left and right nodes according to the distribution
of $p_{\text{RULE}}(\rho|\eta, T)$, then let $T$ as the newly created tree from step 3 and re-apply
steps 2 and 3 to the new children nodes.

BLTREED model was fitted based on standardized data, so same prior can be used
independently for parameters in the terminal nodes and they were considered as a
multivariate normal distribution with zero mean and variance matrix proportional to the
identity for these parameters (74, 84).
Posterior distribution function $p(T|X, y)$ was computed with combining the marginal likelihood function $p(Y|X, T)$ and tree prior $p(T)$ as follows:

$$p(T|X, y) \propto p(y|X, T) \ p(T)$$

(3)

Where $p(Y|X, T)$ is as follow:

$$p(y|X, T) = \int p(y|X, \Theta, T) \ p(\Theta|T) \ d\Theta = \prod_{i=1}^{X} \int \prod_{h=1}^{n_i} p(y_{ih}|x_{ih}, B_i) \ p(B_i) \ dB_i$$

(4)

Which $p(y|X, \Theta, T)$, $(y_{ih}, x_{ih})$ and $n_i$ show the data likelihood function, observed values for $h_{th}$ observation in $i_{th}$ node and the number of observations in $i_{th}$ node, respectively. The integral of equation 4 hasn’t closed form, so Laplace approximation was used to solve it (74, 84).

Chipman et al. (73, 74) utilize a Metropolis-Hastings algorithm to simulate equation (3) for finding trees with high posterior distribution. The Metropolis-Hastings algorithm simulates a Markov chain sequence of trees namely $T^0, T^1, T^2, ...$ The simulation algorithm was implemented with multiple restarts for reasons that mentioned in Chipman et al. (73, 74).

2.7. Data Analysis

BLTREED models were fitted by using predictor variables such as hemoglobin (Hb), mean cell volume (MCV), mean cell hemoglobin (MCH) and red cells distribution width (RDW) for differential diagnosis of βTT from IDA.
BLTREED model fitted using 8 restarts with 6000 iterations per restart and use a prior standard deviation of 20 for the logit coefficients (84). For determining the pair of \((\alpha, \beta)\), BLTREED model was fitted with two choices 0.5 and 0.95 for \(\alpha\) parameter, and four choices for \(\beta\) (a range 0.5-2 by step 0.5), then selected the pair of \((\alpha, \beta)\) that generate the best tree with smallest FNR.

Differential performance of the Bayesian classification tree was evaluated using criteria such as sensitivity (TPR), specificity (TNR), false negative rate (FNR) and false positive rate (FPR), positive predictive value (PPV) and negative predictive value (NPV), positive likelihood ratio (PLR) and negative likelihood ratio (NLR), accuracy, Youden’s index, area under curve (AUC) and F-measure. AUC can be interpreted as an overall performance measure in the classification of the tree models.

Criteria such as F-measure, Youden’s index, accuracy, PLR, NLR (a good diagnostic test or has NLR < 0.1 and a good diagnostic test has PLR > 10) and AUC take both sensitivity and specificity into consideration, so they can present the performance of model more accurately than other criteria. \(P < 0.05\) was considered to be statistically significant.

2.8. Software

Data were analyzed by free software (http://gsbwww.uchicago.edu.fac.robert.mcculloch.research.code.CART.index.html) based on Chipman et al. (2002) that was developed for fitting BTREED model, R 3.0.3 used for compute performance measures (ePiR and pROC), split data to training data set and test data set (caTools package).

3. Results
A total of 537 patients were diagnosed as βTT including 299 (56%) women and 238 (44%) men, while 370 patients were diagnosed as IDA included 293 (79%) women and 77 (21%) men. Table 1 shows Mean, standard deviation (SD) of laboratory parameter as predictor variables across the type of hypochromic microcytic anemia (βTT and IDA).

The tree structure of BLTREED model was shown in figures 1. The first split of the tree was based on MCV, it showed that MCV is an important predictor in differentiation between the types of hypochromic microcytic anemia. Another predictor which used as second splitting variable in tree structure was HB. According to the presented tree, four homogenous sub-groups were extracted from data which obtained four diagnostic discrimination rules for differentiating between βTT and IDA (Table 2). This classifying scheme showed that values of MCV ≤ 72.70 screening the βTT patients.

Predictive performance of the model in differentiation between βTT and IDA calculated based on confusion matrix (Table 3). The obtained tree showed the highly TPR, TNR, PPV, NPV, Youden's Index, accuracy and F-measure in differentiation between βTT and IDA (Table 4).

In addition, the model has NLR < 0.1 and it could be concluded that BLTREED has good diagnostic accuracy for discriminating the patients. Table 5 shows AUCs of the model from ROC analysis that were statistically significant (p < 0.001) and showed the excellent diagnose accuracy in differentiation between the types of hypochromic microcytic anemia.

4. Discussion:

In this paper, we used BLTREED model as a Bayesian decision tree as the differential diagnostic tool for thalassemia diagnosis. This is a first study that uses BLTREED
model in the hematological data. The Bayesian decision tree used to solve uncertainly
problems of conventional tree-based methods (74, 84, 85). This model was
implemented by using Hb, MCV, MCH and RDW as independent variables. Based on
our result, MCV and Hb were main predictor parameters in differential diagnostic and
it showed that the patient with βTT has lower values of MCV.

In previous studies that used the different conventional decision trees for differential
diagnosis βTT from IDA, the first split of all algorithms was based on MCV and they
also concluded that MCV was an important predictor variable in discrimination of IDA
and βTT (35, 37). The performance of BLTREED model that evaluated by using
sensitivity, specificity, false negative and positive rate, positive and negative predictive
value, exhibited the high performance of the differential diagnosis of βTT from IDA. In
addition, positive likelihood ratio and negative likelihood ratio, accuracy, Youden’s index and F-measure showed that BLTREED has good diagnostic accuracy
for discriminating the patients. It was truly classified 96% of βTT patient. Furthermore,
AUC as an index of overall performance showed excellent and significant accuracy
(99, 98) in training and test data, respectively in differential diagnostic of βTT and IDA.

Other studies that used different data mining techniques and decision trees based on
frequentist approach of fitting revealed the high performance and accuracy but lower
than our result (34-37, 70). BLTREED model improves the classification performance
by solving the uncertainty of previous models (74, 84).

The diagnostic performance of BLTREED was better than other discrimination
methods (classification trees or hematological discrimination indices) in past studies
for differentiating βTT from IDA. These studies are as follows: Setsirichok et al. (2012)
used C4.5 decision tree, naïve Bayes (NB) classifier and multilayer perceptron (MLP)
for classifying eighteen classes of thalassemia abnormality (34). Bellinger et al. (2015)
used classification algorithms like J48 decision tree, support vector machines (SVM), k-nearest neighbors (k-NN), MLP and NB for differentiating between βTM, IDA and co-occurrence of these disorders (70). AlAgha et al. (2018) compared the diagnostic performance of different classification algorithms such as J48, k-NN, artificial neural networks (ANN) and NB for classifying β-thalassemia carriers (86). Jahangiri et al. (2017) utilized classification tree algorithms such as CHAID, E-CHAID, CART, QUEST, GUIDE and CRUISE for differential diagnosis of βTT from IDA. They indicated that CRUISE algorithm has the best diagnostic performance with similar to and the present study, but this classic algorithm uses greedy algorithm for tree generating and cannot explore the tree space more than Bayesian tree approaches. Also, many studies compared the diagnostic performance of hematological discrimination indices and BLTREED showed better performance in comparison to them (19-22, 26, 28-33, 87-102).

5. Conclusion

In the present study, BLTREED model showed excellent diagnostic accuracy for differentiating βTT from IDA. According to the advantages of Bayesian tree-based methods like generating a small and more interpretable tree, and lack of uncertainty of different conventional decision trees, this method can be helpful along with other laboratory parameters for discriminating between these two anemia disorders. Also, understanding tree-based methods are easy and need not a statistical experience, so this advantage can help physicians in making the right clinical decision.

Table 1. Hematological data of study groups presented as mean ± SD

|        | βTT (n = 537) | IDA (n=370) | P-value |
|--------|---------------|-------------|---------|
| MCV    | 62.17 ± 4.14  | 71.87 ± 6.93 | < 0.001 |
| MCH    | 19.75 ± 1.45  | 21.85 ± 2.99 | < 0.001 |
| Hb     | 11.20 ± 1.41  | 10.82 ± 2.43 | < 0.001 |
| RDW    | 15.88 ± 1.43  | 16.04 ± 2.31 | 0.94    |

Table 2. Subgroups extracted for diagnose of βTT and IDA patients by BLTREED model

| Subgroup | Conditions                  | Diagnose label |
|----------|-----------------------------|----------------|
| A        | MCV ≤ 70.70 + HB ≤ 12.70    | βTT            |
| B        | 70.70 < MCV ≤ 72.70 + HB ≤ 12.70 | IDA            |
| C        | HB ≤ 12.70 + MCV< 72.70     | βTT            |
| D        | MCV> 72.70                  | IDA            |
Table 3. Confusion table of BLTREED model for training data set and test data set

|                | Training data set |          | Test data set |          |
|----------------|-------------------|----------|---------------|----------|
|                | Predicted         | Predicted|                |          |
| Actual         | βTT               | IDA      | Total         | βTT      | IDA      | Total |
| βTT            | 363               | 13       | 376           | 155      | 6        | 161   |
| IDA            | 25                | 234      | 259           | 8        | 103      | 111   |
| Total          | 388               | 247      | 635           | 163      | 109      | 272   |

Table 4. Sensitivity, specificity, false positive and negative rate, positive and negative predictive values, accuracy, Youden’s index, positive and negative likelihood ratio and F-measure of BLTREED model in prediction of IDA and βTT groups and their 95% exact confidence interval for training and test data set
| Diagnostic Variables | Training data set | Test data set |
|----------------------|-------------------|--------------|
| TPR                  | 97 (94 – 98)      | 96 (92 – 99) |
| TNR                  | 90 (86 – 94)      | 93 (86 – 97) |
| FNR                  | 3 (2 – 6)         | 4 (1 – 8)    |
| FPR                  | 10 (6 – 14)       | 7 (3 – 14)   |
| PPV                  | 94 (91 – 96)      | 95 (91 – 98) |
| NPV                  | 95 (91 – 97)      | 94 (88 – 98) |
| Youden's Index       | 87 (80 – 92)      | 89 (78 – 95) |
|                   |       |       |
|-------------------|-------|-------|
| **Accuracy**      | 94    | 95    |
|                   | (92 – 96) | (91–97) |
| **LR+**           | 10    | 13.36 |
|                   | (7 – 14) | (7–26)  |
| **LR−**           | 0.04  | 0.04  |
|                   | (0.02 – 0.07) | (0.02 – 0.09) |
| **F–measure**     | 0.96  | 0.96  |
Table 5. Area under Roc Curve of BTREED model in prediction of IDA and βTT groups for training and test data set (SE: Standard Error of AUC, CI: Confidence Interval)

|       | Training data set | Test data set |
|-------|-------------------|---------------|
| AUC   | 0.99              | 0.98          |
| SE    | 0.003             | 0.009         |
| 95% CI| 0.98–0.99         | 0.96–0.99     |
| P-value| < 0.001         | < 0.001       |
