IRS-Assisted UAV Communications with Imperfect Phase Compensation

M. Al-Jarrah, Member, IEEE, A. Al-Dweik, Senior Member, IEEE, E. Alsusa, Senior Member, IEEE, Y. Iraqi, Senior Member, IEEE, and M.-S. Alouini, Fellow, IEEE

Abstract

This work presents a performance analysis on unmanned aerial vehicles (UAVs) assisted wireless communications systems, where one of the UAVs supports intelligent reflecting surfaces (IRS). As the estimation and compensation of the end-to-end phase for each propagation path is prone to errors, imperfect phase compensation at the IRS is taken into consideration. The performance is derived in terms of symbol error rate (SER) and outage probability, where the phase error is modeled using the von Mises distribution. The analysis utilises the Sinusoidal Addition Theorem (SAT) when the number of reflectors $L \leq 3$, and the Central Limit Theorem (CLT) when $L \geq 4$. The achieved results show that accurate phase estimation and compensation is critical for IRS based systems, particularly for a small number of reflecting elements. For example, the SER at $10^{-3}$ degrades by about 5 dB when the von Mises concentration parameter $\kappa = 2$ and $L = 30$, but the degradation for the same $\kappa$ surges to 25 dB when $L = 2$. The air-to-air (A2A) channel for each propagation path is modeled as a single dominant line-of-sight (LoS) component, and the results are compared to the Rician channel model. The obtained results reveal that the considered A2A model can be used to accurately represent the A2A channel with Rician fading.

Index Terms

Bit error rate (BER), outage probability, Rician fading, intelligent reflecting surfaces (IRS), imperfect phase estimation, sinusoidal addition theorem (SAT), unmanned aerial vehicle (UAV), flying network, von Mises density, 6G.

I. INTRODUCTION

Intelligent reflecting surfaces (IRSs), also called metasurfaces, is an emerging technology that has recently received extensive attention [1]–[13]. The main aim of IRS is controlling the propagation medium to improve the quality of wireless signals by increasing their total energy. The IRS technology
is expected to play a significant role in future wireless networks, such as sixth generation (6G), because of its positive impact on energy and spectral efficiency. IRS consist of a large number of passive antenna elements that can introduce phase-shifts to wireless signals before reflecting them to their destination. For efficient transmission, multiple reflectors are used for a certain destination, and the introduced phase shifts are selected such that the reflected signals add coherently in the channel. As a result, the signal-to-noise ratio (SNR) increases considerably, which allows using high modulation orders to improve the spectral efficiency.

Likewise, the use of unmanned aerial vehicles (UAVs) as flying networks has recently attracted a substantial attention in both academic and industrial sectors. Because of their autonomy, flexibility and cost efficiency, there has been a significant growth in the deployment of UAVs in many applications including surveillance, localization and tracking, remote sensing, search and rescue missions, aerial imaging, and military applications. In addition, UAVs can be integrated with base stations (BS) to construct cost and energy efficient flying BSs. These flying BSs can provide integrated access and backhaul (IAB) solutions with significantly improved coverage, capacity and connectivity. Furthermore, UAV based IAB can assist the terrestrial cellular network that may suffer from congestion due to extremely high traffic or physical failure due to emergencies such as storms and earthquakes [14]–[20].

Although IRS may lead to significant SNR gain, such gain is highly dependent on the system capability to accurately estimate and compensate the end-to-end phase for each IRS element, which is one of the main challenges for such technology. Therefore, channel estimation, phase shift design, and performance evaluation with imperfect phase have received extensive attention [13], [21]–[29]. The phase estimation and compensation problem becomes more critical when IRS is integrated with flying networks. In such contexts, UAV assisted communications in urban areas may employ IRSs to improve the signal quality in the absence of line-of-sight (LoS) connectivity between certain UAVs due to Skyscrapers [12], [30]–[39]. Nevertheless, UAVs are typically moving causing fast variation to the channel phase, which complicates the overall phase processing. Channel variations are expected even when the UAV is hovering due to the UAV wobbling [40], and thus, the coherence time of the channel will be generally short. Therefore, the IRS might be provided with outdated phase information. Hence, performance analysis of IRS based systems while considering imperfect co-phasing process is crucial.
A. Related Work

existing research work on IRS has covered a broad range of topics such as, but not limited to, power and energy optimization [1], [8], [13], [33], physical layer security [7], resource allocation with non orthogonal multiple access (NOMA) [9], full duplex cognitive radio [5], and symbol-level precoding [11]. The integration of IRS and simultaneous wireless information and power transfer (SWIPT) is considered in [4]. Gao et al. considered the design of distributed IRSs with passive reflecting beamforming that exploits statistical channel state information (CSI) and analyzed the ergodic achievable rate. Xie et al. [3] formulated and solved a joint optimization problem for the coordinated transmit and reflective beamforming for maximizing the minimum weighted received signal-to-interference-plus-noise ratio (SINR) at users subject to transmit power constraints.

The integration of IRSs and UAVs has also been considered in the literature. For example, Lu et al. [12] proposed deploying flying platforms such as balloons or UAVs equipped with IRS to serve terrestrial users. The presented results show that flying IRS has an extra degree of freedom because of the capability of relocating the IRS to optimize certain system parameters such as maximizing the SNR. Moreover, it is shown that flying IRSs require less number of elements to achieve a certain gain as compared to terrestrial IRSs. Jiao et al. [30] investigated the design of a NOMA-based IRS-UAV system to maximize the rate of the near user while guaranteeing the target rate of the far user by optimizing the UAV location, transmit beamforming and phase shift of IRS. Ma et al. [31] used the IRS to direct the signal to the UAV to increase its received signal strength. The obtained results show that significant signal improvement can be obtained using a small number of reflectors given that the location of the IRSs and phase of the reflected signals are optimized. Ge et al. [32] considered a system where a single UAV transmits to multiple terrestrial IRSs. The work focused on the optimal design of beamforming at the UAV, IRSs and the UAV’s trajectory to maximize the received power at the ground users. Mohamed and Aissa [33] considered the downlink of a multi-antenna BS that communicates to a single antenna user via an IRS-UAV platform. The work evaluates the advantage of the IRS to maximize the total energy efficiency of the system by jointly optimizing the beamforming vector at the BS and the phase shifts matrix of the IRS. Various optimization techniques under the assumption of perfect CSI. Several other articles have considered integrated IRS-UAV [34]–[39] to minimize the transmit power, maximize the SNR, maximize the spectral efficiency, or maximize the sum rate. Nevertheless, they did not consider the error or outage probability analysis, or the impact of imperfect phases estimation and control process.
The impact of the phase modeling, estimation and compensation has been considered by Abeywickrama et al. [13], who proposed a more practical phase model that considers the correlation between the phase and amplitude of the individual reflected signals. The authors formulated an optimization problem to minimize the total transmit power by jointly designing the transmit and IRS beamforming. Although the phase model is interesting, the phase estimation and control processes are considered perfect. Moreover, the error and outage probabilities are not considered. The authors in [21] considered the outage probability of IRS-NOMA with coherent and random phase processing. For the coherent case, the phase estimation and compensation were considered ideal, while the random phase was considered uniform and discrete. The presented outage probability results show that IRS can still provide some gain even when the phase is random. The work does not consider the error probability nor the coherent scenario with phase error. The CSI estimation and discrete phase model are considered in [22], where the presented results, in terms of the achievable rate, demonstrate the significant impact of using a discrete phase. Hu et al. [23] considered the imperfect phase scenario by introducing user location uncertainty. The objective of this work is to minimize the transmit power subject to quality of service (QoS) constraint. CSI estimation has also been considered in [24]–[29], though the focus of these works is mostly on evaluating the CSI estimates accuracy, rather than evaluating its impact on the system performance.

The error probability analysis of IRS based systems has been considered in [41]–[46]. Nevertheless, the only work that considered the bit error rate with imperfect phase estimation is [47], where the phase error and fading coefficients are modeled as von Mises and Nakagami-\(m\) distributions, respectively. However, the presented derivations in [47, Eq. 13, Eq. 14] actually correspond to the case of uniform phase distribution [48], [49]. Consequently, the analysis is applicable to the random phase scenario considered in [21].

B. Motivation and Main Contributions

As can be noted from the surveyed literature, integrating IRS with flying networks using UAVs has a strong potential to improve UAVs connectivity in urban areas. The extra degree of freedom that UAVs have can enable optimizing the IRS link by selecting the most suitable placement for the IRS-UAV. Nevertheless, achieving the ultimate gain using IRS is highly dependent on the reliability of the phase estimates and co-phasing processes. Practically speaking, both operations are not perfect, and thus, the ultimate gain promised by the IRS technology may not be guaranteed, which is particularly

TABLE I: Nomenclature.

| Symbol | Definition                              | Symbol | Definition                             |

| K      | Rician fading factor                    |        |                                        |

critical for IRS-UV configurations. Therefore, this work analyzes the performance of IRS assisted UAV communications under a more realistic scenario, where the phase estimation and co-phasing processes are imperfect. The phase error is modeled using the von Mises distribution, and the channels are considered to have a dominant LoS component. The performance is evaluated in terms of symbol error rate (SER) and outage probability, where exact closed-form expressions are derived for a small number of reflecting elements, and accurate approximations are derived for a large number of reflectors. The obtained results show that the gain achieved using IRSs depends strongly on the reliability of the co-phasing process, particularly when the number of reflectors is small. For a large number of reflectors, the system sensitivity to the co-phasing process decreases significantly.

C. Notations

For the readers’ convenience, the nomenclature and main symbol definitions are given in Tables I and II, respectively.

D. Paper Organization

The rest of the paper is organized as follows. Sec. II presents the system and channel models. Sec. III presents the derivation of the signal envelope distribution for different number of reflectors. Secs. IV and V present the SER and outage probability analysis. Numerical and simulation results are presented in Sec. VI, and finally the paper is concluded in Sec. VII.
**TABLE II: Frequently used definitions.**

| $A_2 = (A_1 - A_2)^2$ | $I_0(3)(\kappa) = I_0(\kappa_1)I_0(\kappa_2)I_0(\kappa_3)$ |
| $A_3 = (A_1 + A_2)^2$ | $A_i = g_i\tilde{h}_i$ |

**Fig. 1: IRS assisted flying networks.**
II. SYSTEM AND CHANNEL MODELS

This work considers an IRS-assisted UAV communications as shown in Fig. 1. In flat fading channels, the passband signal arriving at the $i$th reflecting element can be written as

$$ r_i(t) = h_i s \cos \left( \omega_c t - \psi_i \right) $$

$$ = h_i a \cos \left( \omega_c t + \varphi - \psi_i \right), \ i = [1, 2, \ldots, L] $$

(1)

where $s$ is the complex information symbol, $s = ae^{j\varphi}$, $\omega_c = 2\pi f_c$, $f_c$ is the carrier frequency, $h_i$ is the channel fading coefficient between the transmitter and the $i$th reflecting element. The phases $\psi_i \forall i$ are typically modeled as mutually independent and identically distributed (i.i.d.) random variables that are uniformly distributed over $[-\pi, \pi]$ [50]. Each IRS element shifts the signal phase by a value $\theta_i$ and attenuates the signal by a factor $g_i$. Therefore, using the same assumptions for the signal arriving at the IRS, the reflected $L$ signals arriving from the IRS at the receiver can be written as

$$ y(t) = \sum_{i=1}^{L} g_i h_i h_i a \cos \left[ \omega t + \varphi - \psi_i - \phi_i + \theta_i \right] + z(t) $$

(2)

where $h_i$ and $\phi_i$ are attenuation and phase shift caused by the channel between the $i$th IRS element and the receiver, $z(t)$ is the additive white Gaussian noise (AWGN). To maximize the received SNR $\theta_i$ is selected such that $\theta_i = \psi_i + \phi_i$, and then $y(t)$ can be written as

$$ y(t) = \left( \sum_{i=1}^{L} g_i h_i h_i a \right) \cos \left[ \omega t + \varphi \right] + z(t). $$

$$ = B_L \cos \left[ \omega_c t + \varphi \right] + z(t). $$

(3)

However, it is practically infeasible to estimate and compensate the phases $\psi_i$ and $\phi_i$. Therefore, $y(t)$ with imperfect phase estimation and compensation should be written as

$$ y(t) = \sum_{i=1}^{L} g_i h_i h_i a \cos \left[ \omega t + \varphi - \psi_i - \phi_i + \hat{\theta}_i \right] + z(t). $$

(4)
where \( \hat{\theta}_i = \hat{\psi}_i + \hat{\phi}_i \), \( \hat{\psi}_i \) and \( \hat{\phi}_i \) are the estimated and compensated versions of \( \psi_i \) and \( \phi_i \), respectively. Thus,

\[
y(t) = a \sum_{i=1}^{L} g_i h_i h_i \cos[\omega t + \varphi + \epsilon_i] + z(t)
\]

\[
= a \sum_{i=1}^{L} A_i \cos[\omega t + \varphi + \epsilon_i] + z(t)
\]

(5)

where \( \epsilon_i = \hat{\theta}_i - \theta_i \), \( g_i h_i h_i \triangleq A_i \in (-\infty, \infty) \), and \( \epsilon_i \in [-\pi, \pi] \). Using the Sinusoidal Addition Theorem (SAT) [48], [49] we obtain

\[
y(t) = a B_L \cos(\omega t + \varphi + \phi_L), \quad t \geq 0
\]

(6)

where

\[
B_L^2 = ||A||^2 + 2 \sum_{L \geq j > k \geq 1} A_j A_k \cos(\epsilon_j - \epsilon_k)
\]

(7)

\[
\zeta_L = \tan^{-1}\left[\frac{\sum_{i=1}^{L} A_i \sin(\epsilon_i)}{\sum_{i=1}^{L} A_i \cos(\epsilon_i)}\right]
\]

(8)

and \( ||\cdot|| \) is the Euclidian norm.

At the receiver, the carrier signal will be removed and the data symbol during the \( \ell \)th signaling period can be expressed as

\[
d = \frac{1}{T_s} \int_{0}^{T_s} 2y(t)e^{-j(\omega t + \hat{\zeta}_L)} \, dt
\]

\[
= a B_L e^{i(\varphi + \phi_L - \hat{\zeta}_L)} + z
\]

(9)

where \( \hat{\zeta}_L \) is an estimate of the accumulated phase offset \( \zeta_L \), and \( z \sim \mathcal{CN}(0, 2\sigma_z^2) \) is the AWGN. In slow fading channels, \( \zeta_L \) can be estimated and compensated accurately, and thus \( \hat{\zeta}_L \approx \zeta_L \). By noting that \( ae^{j\varphi} = s \), then

\[
d = B_L s + z.
\]

(10)

The SER can be derived as,

\[
\bar{P}_e = \int_{0}^{\infty} (P_e|b_L) \ f_{B_L}(b_L) \ dB_L
\]

(11)

where \( f_{B_L}(b_L) \) is the probability density function (PDF) of the signal envelope \( B_L \) and \( P_e|b_L \) is the conditional SER given \( b_L \). The elements of \( A_L = [A_1, ..., A_L] \) depend on the channel model. For air-to-air channels (A2A), the signal typically has a strong LoS and some reflected components, and
thus, such channels can be modeled using the Rician fading [51]–[57]. However, as the measurements indicated, the Rice factor $K$ for A2A channel is about 20 dB, and the received signal power may remain constant for long time periods [51]–[57]. Consequently, the channel coefficients $A_1, A_2, ..., A_L$ are not suffering from small scale fading, and the large scale fading is dominated by the free space path loss. Nevertheless, the obtained results in Sec. VI show that the constant fading coefficients model can be used to closely approximate the Rician fading channel with high $K$ values.

### III. PDF OF THE SIGNAL ENVELOP $B_L$

For a given values of $A_1, A_2, ..., A_L$, the PDF of $B_L$ can be computed as [48], [49]

$$f_{B_L}(b_L) = \frac{b_L}{\pi} \int_{-\infty}^{\infty} e^{-j b_L^2 t} \int_{-\pi}^{\pi} e^{j \frac{t}{L-1} + A_R^2 + 2 A_L b_L \cos (\epsilon_L - \zeta_L - 1)} \times f_{\epsilon}(\epsilon) d\epsilon dt$$

(12)

where $\epsilon = [\epsilon_1, \epsilon_2, ..., \epsilon_L]$ are the phase errors for the $L$ reflecting elements. The PDF $f_{B_L}(b_L)$ is derived in [48], [49] for the uniform phase $\epsilon_i \sim U [-\pi, \pi] \forall i$, and has been used to model fading, interference and jamming in wireless systems [50], [58], [59]. However, when the SAT is used to model phase estimation errors, the uniform phase model is not applicable for such scenarios [60], because the phase error generally follows the von Mises distribution with mean $\mu$ and shape parameter $\kappa$ [61],

$$f_{\epsilon_i}(\epsilon_i) = \frac{e^{\kappa_i \cos (\epsilon_i - \mu_i)}}{2\pi I_0(\kappa_i)}$$

(13)

where $I_0(.)$ is the modified Bessel function of the first kind and order $q$. As can be noted form (13), the uniform PDF is a special case of the von Mises PDF with $\kappa = 0$, which corresponds to the worst case phase error. For large values of $\kappa$, the PDF becomes concentrated around $\mu$, which indicates small phase errors, and setting $\mu = 0$ implies that the phase error is unbiased. Although in theory $\kappa \in [0, \infty)$, typical values of $\kappa$ occupy a smaller bounded range. For example, least square channel estimation (LSCE) using a single pilot symbol provides $\kappa = [1.25, 3, 8, 25, 250]$ for $\text{SNR} = [-5, 0, 5, 10, 20]$, respectively.

In the following subsections, the exact PDF $f_{B_L}(b_L)$ is derived for the cases of $L = 2, 3$, and the PDFs for $L \geq 4$ are approximated using the Central Limit Theorem (CLT). Moreover, for all scenarios, the phase error will be considered unbiased, $\mu_i = 0 \forall i$, and the values of $\kappa_i$ are considered unequal deterministic variables. The phase errors $\epsilon_i \forall i$ are i.i.d. von Mises random variables.
A. The Signal Envelope PDF for $L = 2$, $f_{B_2}(b_2)$

For $L = 2$, $\zeta_{L-1} = \zeta_1 = \epsilon_1$ and $b_1 = A_1$. Substituting these terms in (12) and rearranging the order of integration gives

$$
f_{B_2}(b_2) = \frac{b_2}{4\pi^3 I_0^{(2)}(\kappa)} \int_{-\infty}^{\infty} e^{-jt(b_2^2-A_1^2-A_2^2)} \int_{-\pi}^{\pi} e^{\kappa_1 \cos(\epsilon_1)} \left[ \int_{-\pi}^{\pi} e^{2jtA_1A_2 \cos(\epsilon_2-\epsilon_1)+\kappa_2 \cos(\epsilon_2)} d\epsilon_2 \right] d\epsilon_1 dt.
$$

(14)

It should be noted that when the phases distribution is not uniform, it can’t be assumed that one of these phases is zero as reported in [48], [49], which implies that there is an additional integration that should be solved for the von Mises PDF. The integral inside the brackets can be evaluated with respect to $\epsilon_2$ as

$$
I_2 = \int_{-\pi}^{\pi} e^{2jtA_1A_2 \cos(\epsilon_2-\epsilon_1)+\kappa_2 \cos(\epsilon_2)} d\epsilon_2 = 2\pi I_0 \left( 2 |A_1A_2| \sqrt{-t^2 + K^2 + 2jtK \cos(\epsilon_1)} \right).
$$

(15)

By substituting (15) in (14) and rearranging the integration order we obtain

$$
f_{B_2}(b_2) = \frac{b_2}{4\pi^3 I_0^{(2)}(\kappa)} \int_{-\pi}^{\pi} e^{\kappa_1 \cos(\epsilon_1)} \left[ \int_{-\infty}^{\infty} e^{-jt \tilde{I}_2} d\epsilon_1 \right] d\epsilon_2.
$$

(16)

The integral inside the brackets, $I_3$, can be evaluated using the following tabulated integral [62, 6.616.1]

$$
\int_{0}^{\infty} e^{-\alpha x} I_0 \left( \beta \sqrt{x^2 + 2\lambda x} \right) dx = \frac{1}{\sqrt{\alpha^2 + \beta^2}} e^{\lambda \left( \alpha - \sqrt{\alpha^2 + \beta^2} \right)}
$$

(17)

which after some straightforward manipulations can be written as,

$$
\int_{-\infty}^{\infty} e^{-\alpha x} I_0 \left( -j\beta \sqrt{x^2 + 2\lambda x} \right) dx = \frac{1}{\sqrt{\alpha^2 + \beta^2}} \left[ e^{\lambda \left( \alpha - \sqrt{\alpha^2 + \beta^2} \right)} + e^{\lambda \left( \alpha + \sqrt{\alpha^2 + \beta^2} \right)} \right].
$$

(18)

By using the change of variable $x = t + v$,

$$
\int_{-\infty}^{\infty} e^{-\alpha x} I_0 \left( -j\beta \sqrt{x^2 + 2\lambda x} \right) dx = e^{-\alpha v} \int_{-\infty}^{\infty} e^{-\alpha t} I_0 \left( -j\beta \sqrt{t^2 + 2t(v + \lambda) + v^2 + 2\lambda v} \right) dt.
$$

(19)

Therefore, $I_3$ can be evaluated as

$$
I_3 = e^{\alpha v} \frac{2\pi}{B} \left[ e^{\lambda (\alpha - B)} + e^{\lambda (\alpha + B)} \right], \quad \alpha^2 + \beta^2 \geq 0.
$$

(20)
By noting that $v + \lambda = -jK \cos(\epsilon_1)$ and $v^2 + 2\lambda v = -K^2$, $f_{B_2}(b_2)$ can be expressed as

$$f_{B_2}(b_2) = \frac{b_2}{2\pi^2 B I_0^{(2)}(\kappa)} \int_{-\pi}^{\pi} \left[ e^{(iK\tilde{\alpha} + \kappa_1)\cos(\epsilon_1)} - KB\sin(\epsilon_1) \right] d\epsilon_1$$

$$= \frac{b_2}{\pi B I_0^{(2)}(\kappa)} \left[ I_0 \left( (K\tilde{\alpha} + \kappa_1)^2 + [KB]^2 \right) + I_0 \left( (K\tilde{\alpha} + \kappa_1)^2 + [KB]^2 \right) \right]$$

$$= \frac{2b_2}{\pi B I_0^{(2)}(\kappa)} I_0 \left[ \sqrt{(2KA_1 A_2 + \kappa_1)^2 + K^2 (4A_1^2 A_2^2 + 4A_1^2 A_2^2)} \right]$$

$$= \frac{2b_2}{\pi B I_0^{(2)}(\kappa)} I_0 \left[ \sqrt{(\kappa_1 - \kappa_2)^2 + \frac{\kappa_2 \kappa_1}{A_1 A_2}} (b_2^2 - A_2) \right]$$

which after some algebraic simplifications, it can be simplified to

$$f_{B_2}(b_2) = \frac{2b_2}{\pi B I_0^{(2)}(\kappa)} I_0 \left[ \sqrt{\kappa_1^2 + \kappa_2^2 + 2\kappa_2 \kappa_1 B_2^2} \right], |B_2| \leq 1$$

$$= \frac{2b_2 I_0}{\pi \sqrt{(A_3 - b_2^2) (b_2^2 - A_2)} I_0^{(2)}(\kappa)}, |B_2| \leq 1.$$

(21)

The condition $|B_2| \leq 1$ can be solved as

$$\left| \frac{b_2^2 - A_1^2 - A_2^2}{2A_1 A_2} \right| \leq 1$$

(23)

which gives

$$B_{2,m} \leq b_2 \leq B_{2,M}$$

(24)

where $B_{2,m} = |A_1 - A_2|$ and $B_{2,M} = A_1 + A_2$. It can be noted that $f_{B_2}(b_2)$ derived in [48], [49] is just a special case of (22) where $\kappa_i = 0 \ \forall i$.

Fig. 2a shows the PDFs of $f_{B_2}(b_2)$ where the individual signal amplitudes $A_i = 1 \ \forall i$. As can be noted from the figure, the derived formula in (22) matches the simulation results for all the considered values of $\kappa$, including $\kappa = 0$, which corresponds to the uniformly distributed phases. The figure shows that large phase errors may drive the amplitude $B_2$ below the $\min\{A_1, A_2\}$, which implies that the error rate would be worse than the case without IRS. Increasing the value of $\kappa$, makes the envelope more concentrated around $A_1 + A_2$, which implies that the IRS will provide a gain of about 6 dB in terms of SNR.
Fig. 2: The PDF of the signal envelope for different values of $\kappa$ for $L = 2, 3$, $A_i = 1 \forall i$.

B. The Signal Envelope PDF for $L = 3$, $f_{B_3}(b_3)$

Using the same assumptions of $L = 2$, $f_{B_3}(b_3)$ can be expressed as

$$f_{B_3}(b_3) = \frac{b_3}{8\pi^4 I_0^{(3)}(\kappa)} \int_{-\infty}^{\infty} e^{-jb_3^2t} \int_{-\pi}^{\pi} \int_{-\pi}^{\pi} e^{jt(b_3^2 + A_3^2 + 2A_3b_2 \cos(\epsilon_3 - \zeta_2))} e^{\sum_{i=1}^{L} \kappa_i \cos(\epsilon_i)} d\epsilon_1 d\epsilon_2 d\epsilon_3 dt.$$  

(25)

where $b_3^2 = A_3^2 + A_2^2 + 2A_1A_2 \cos(\epsilon_2 - \epsilon_1)$ and $\zeta_2 = \tan^{-1} \left[ \frac{A_1 \sin(\epsilon_1) + A_2 \sin(\epsilon_2)}{A_1 \cos(\epsilon_1) + A_2 \cos(\epsilon_2)} \right]$. Hence, the constraint $|B_2| \leq 1$ is also applicable. By substituting the identity

$$\cos(\epsilon_3 - \zeta_2) = \cos(\epsilon_3) \cos(\zeta_2) + \sin(\epsilon_3) \sin(\zeta_2)$$

and evaluating the integral with respect to $\epsilon_3$ gives

$$f_{B_3}(b_3) = \frac{b_3}{4\pi^3 I_0^{(3)}(\kappa)} \int_{-\pi}^{\pi} \int_{-\pi}^{\pi} \frac{1}{B} e^{\kappa_1 \cos(\epsilon_1)} e^{\kappa_2 \cos(\epsilon_2)}$$

$$\times \left[ e^{-K \sin(\zeta_2) \hat{\theta} + \hat{\alpha} K \cos(\zeta_2)} + e^{K \sin(\zeta_2) \hat{\theta} + \hat{\alpha} K \cos(\zeta_2)} \right] 1_{|B_3| \leq 1} d\epsilon_2 d\epsilon_1$$

(26)
\(1_{\{\cdot\}}\) is the indicator function of the set \(\{\cdot\}\). Thus,

\[
f_{B_3}(b_3) = \frac{b_3}{2\pi^3 f_0^{(3)}(\kappa)} \int_{-\pi}^{\pi} \int_{-\pi}^{\pi} \frac{1}{B} e^{\kappa_1 \cos(\epsilon_1) + \kappa_2 \cos(\epsilon_2)} e^{K_0 \cos(\zeta_0) \cosh \left( \frac{K_0 \sin(\zeta_0) B}{2} \right)} 1_{\{||B_3|| \leq 1\}} \, d\epsilon_1 d\epsilon_2.
\]  

(27)

As can be noted from (27), deriving \(f_{B_3}(b_3)\) in closed-form is intractable. Fig. 2b shows \(f_{B_3}(b_3)\) for various values of \(\kappa\), where high values of \(\kappa\) leads the PDF to be mostly concentrated close to the maximum amplitude, i.e., \(B_{3,M} = A_1 + A_2 + A_3\). For the perfect phase estimations case, the anticipated gain provided by the IRS will be about 9.5 dB. Nevertheless, for low values of \(\kappa\), the signal will experience fading, which may cause severe increase to the probability of error. In such scenarios, the error probability without IRS may become less than that with IRS.

C. The Signal Envelope PDF \(f_{B_L}(b_L)\) for \(L \geq 4\)

For large \(L\) values, the CLT can be invoked to compute the PDF \(f_{B_L}(b_L)\). However, by referring to (7), it is easier to compute \(f_{B_L^2}(b_L^2)\). Moreover, because the values of \(B_L\) are bounded by \(B_{L,m} \leq b_L \leq B_{L,M}\), it will be more accurate to use the truncated Gaussian distribution [63] to derive the PDF using CLT. By defining \(y_L \triangleq b_L^2\) for notational simplicity, we obtain

\[
f_{Y_L}(y_L) = \frac{1}{\varpi_L \sqrt{2\pi \sigma_{Y_L}^2}} \exp \left( -\frac{(y_L - m_{Y_L})^2}{2\sigma_{Y_L}^2} \right)
\]

(28)

where \(\varpi_L\) is the truncated PDF normalization factor, which is approximately unity for high values of \(m_{Y_L}\) [63, p. 20], \(m_{Y_L}\) and \(\sigma_{Y_L}^2\) are the mean and variance of the Gaussian PDF, which are given by

\[
m_{Y_L} = \sum_{i=1}^{L} A_i^2 + 2 \sum_{L \geq j > k \geq 1} A_j A_k I_1(\kappa_j) I_1(\kappa_k) I_0(\kappa_j) I_0(\kappa_k)
\]

(29)

and

\[
\sigma_{Y_L}^2 \triangleq \mathbb{E} \left[ Y_L^2 \right] - m_{Y_L}^2
\]

(30)

where

\[
\mathbb{E} \left[ Y_L^2 \right] = \|A\|^4 + 4 \sum_{L \geq j > k \geq 1} \frac{A_j^2 A_k^2}{2} \left( 1 + \frac{I_2(\kappa_j) I_2(\kappa_k)}{I_0(\kappa_j) I_0(\kappa_k)} \right) + 4 \|A\|^2 \sum_{n \geq j > k \geq 1} A_j A_k I_1(\kappa_j) I_1(\kappa_k) I_0(\kappa_j) I_0(\kappa_k)
\]

\[
+ 4 \sum_{L \geq j > k \geq 1} \sum_{L \geq i \geq 1} A_j A_k A_i I_1(\kappa_j) I_1(\kappa_k) I_1(\kappa_i) I_1(\kappa_i) I_0(\kappa_j) I_0(\kappa_k) I_0(\kappa_i) I_0(\kappa_i).
\]

(31)

The derivation of \(m_{Y_L}\) and \(\sigma_{Y_L}^2\) is given in Appendix II.
IV. SER Analysis

A. One Reflector, L = 1

In this case, \( b_1 = \beta_1 h_1 h_1 \triangleq A_1 \), hence the channel is deterministic and based on (10), the instantaneous SNR is \( \gamma_1 = \frac{A_1^2}{\sigma_z^2} \). Therefore, the SER can be expressed as

\[
\bar{P}_e = C_1 Q\left( \sqrt{C_2 \gamma_1} \right)
\]  

(32)

where \( Q(\cdot) \) is the tail distribution function of the standard normal distribution, \( C_1 \) and \( C_2 \) are constants that depend on the modulation scheme [64, Table 6.1, pp. 179].

B. Two Reflectors, L = 2

Because the phase between the two reflectors is random, then the instantaneous SNR \( \gamma_2 = \frac{b_2^2}{\sigma_z^2} \) is also random. Therefore, the average SER \( \bar{P}_e \) can be expressed as

\[
\bar{P}_e = C_1 \int_{B_{2,m}}^{B_{2,M}} Q\left( b_2 \sqrt{\frac{C_2}{\sigma_z^2}} \right) f_{B_2}(b_2) \, db_2
\]

\[
= \frac{2C_1}{\pi I_0^{(2)}(\kappa)} \int_{B_{2,m}}^{B_{2,M}} \frac{b_2 Q\left( b_2 \sqrt{\frac{C_2}{\sigma_z^2}} \right)}{\sqrt{(A_3 - b_2^2) (b_2^2 - A_2)}} I_0 \left[ \sqrt{(\kappa_1 - \kappa_2)^2 + \frac{\kappa_2 \kappa_1}{A_1 A_2} (b_2^2 - A_2)} \right] \, db_2. 
\]  

(33)

By substituting \( f_{B_2}(b_2) \) (22) into (33), substituting \( x = \sqrt{b_2^2 - A_2} \), and noting that \( B_{2,m} = |A_1 - A_2| \) and \( B_{2,M} = (A_1 + A_2) \), then \( \bar{P}_e \) can be written as

\[
\bar{P}_e = \frac{2C_1}{\pi I_0^{(2)}(\kappa)} \int_{0}^{A_1} Q\left( \sqrt{\frac{C_2}{\sigma_z^2} (x^2 + A_2)} \right) I_0 \left[ \sqrt{(\kappa_1 - \kappa_2)^2 + \frac{\kappa_2 \kappa_1}{A_1 A_2} x^2} \right] \, dx.
\]  

(34)

Evaluating the integral in (34) is intractable due to the Bessel function. Therefore, we use the infinite series representation of \( I_0(\cdot) \), which gives

\[
\bar{P}_e = \frac{2C_1}{\pi I_0^{(2)}(\kappa)} \sum_{m=0}^{\infty} \frac{1}{2^{2m} (m!)^2} \int_{0}^{A_1} Q\left( \sqrt{\frac{C_2}{\sigma_z^2} (x^2 + A_2)} \right) \left[ (\kappa_1 - \kappa_2)^2 + \frac{\kappa_2 \kappa_1}{A_1 A_2} x^2 \right]^m \, dx.
\]  

(35)

Using the binomial theorem (35) can be expressed as

\[
\bar{P}_e = \frac{2C_1}{\pi I_0^{(2)}(\kappa)} \sum_{m=0}^{\infty} \frac{1}{2^{2m} (m!)^2} \sum_{k=0}^{m} \binom{m}{k} (\kappa_1 - \kappa_2)^{2(m-k)} \left( \frac{\kappa_2 \kappa_1}{A_1 A_2} \right)^k \int_{0}^{A_1} Q\left( \sqrt{\frac{C_2}{\sigma_z^2} (x^2 + A_2)} \right) x^{2k} \, dx
\]  

(36)
However, the integral in (36) does not have a closed-form solution except for the special case where \( A_1 = A_2 \triangleq A \). Consequently, \( \bar{P}_e \) is reduced to

\[
\bar{P}_e = \frac{2C_1}{\pi I_0^{(2)}(\kappa)} \sum_{m=0}^{\infty} \frac{1}{2^m (m!)^2} \sum_{k=0}^{m} \left( \frac{m}{k} \right) (\kappa_1 - \kappa_2)^{2(m-k)} \left( \frac{\kappa_2 \kappa_1}{A_1^2} \right)^k \int_0^{A_1} \frac{Q \left( \sqrt{\frac{C_2}{\sigma^2}} x \right)}{\sqrt{-x^2 + A_1^2}} x^{2k} dx
\]  

(37)

which can be evaluated as [65, 2.8.3.1, pp. 102],

\[
\bar{P}_e = \frac{C_1}{\pi I_0^{(2)}(\kappa)} \sum_{m=0}^{\infty} \frac{1}{2^m (m!)^2} \sum_{k=0}^{m} \left( \frac{m}{k} \right) (\kappa_1 - \kappa_2)^{2(m-k)} \left( \frac{\kappa_2 \kappa_1}{A_1^2} \right)^k \times \left\{ \frac{A_1^{2k}}{2} B \left( k + \frac{1}{2}, \frac{1}{2} \right) - \sqrt{\frac{C_2}{2\pi \sigma^2}} A_1^{2k+1} B \left( k + 1, \frac{1}{2} \right) \ _2F_2 \left( \left[ k + 1, \frac{1}{2} \right]; \left[ k + \frac{3}{2}, \frac{3}{2} \right]; -\frac{A_1^2 C_2}{2\sigma^2} \right) \right\}
\]  

(38)

where \( _2F_2 \) is the hypergeometric function and \( B \) is the beta function, \( B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)} \).

For the general case of \( A_1 \neq A_2 \), the integral can be solved using the \( Q \)-function approximation [66]

\[
Q(x) \approx \sum_{l=1}^{N} \delta_l \exp \left( -\varepsilon_l x^2 \right), \quad x > 0
\]  

(39)

where \( \delta_l \) and \( \varepsilon_l \) are constants evaluated to minimize the approximation error, their values are given in [66]. Using the \( Q \)-function approximation (36) can be simplified to

\[
\bar{P}_e = \frac{2C_1}{\pi I_0^{(2)}(\kappa)} \sum_{m=0}^{\infty} \frac{1}{2^m (m!)^2} \sum_{k=0}^{m} \left( \frac{m}{k} \right) (\kappa_1 - \kappa_2)^{2(m-k)} \left( \frac{\kappa_2 \kappa_1}{A_1 A_2} \right)^k \sum_{l=1}^{N} \delta_l \exp \left( -\frac{C_2 A_2}{\sigma^2} \varepsilon_l \right) \times \int_0^{A_1} \frac{\exp \left( -\frac{\varepsilon_l C_2}{\sigma^2} x^2 \right)}{\sqrt{-x^2 + A_1^2}} x^{2k} dx
\]  

(40)

Substituting \( u = x^2 \) yields

\[
\bar{P}_e = \frac{C_1}{\pi I_0^{(2)}(\kappa)} \sum_{m=0}^{\infty} \frac{1}{2^m (m!)^2} \sum_{k=0}^{m} \left( \frac{m}{k} \right) (\kappa_1 - \kappa_2)^{2(m-k)} \left( \frac{\kappa_2 \kappa_1}{A_1 A_2} \right)^k \sum_{l=1}^{N} \delta_l \exp \left( -\frac{C_2 A_2}{\sigma^2} \varepsilon_l \right) \times \int_0^{A_1^2} \exp \left( -\frac{\varepsilon_l C_2}{\sigma^2} u \right) u^{k-0.5} du
\]  

(41)

Thereafter, [67, 2.3.6.1, pp. 324] is used to solve the integral, which gives,

\[
\bar{P}_e = \frac{C_1}{\pi I_0^{(2)}(\kappa)} \sum_{m=0}^{\infty} \frac{1}{2^m (m!)^2} \sum_{k=0}^{m} \left( \frac{m}{k} \right) (\kappa_1 - \kappa_2)^{2(m-k)} \left( \frac{\kappa_2 \kappa_1}{A_1 A_2} \right)^k \sum_{l=1}^{N} \delta_l \exp \left( -\frac{C_2 A_2}{\sigma^2} \varepsilon_l \right) \times B \left( k + 0.5, 0.5 \right) (4A_1 A_2)^k \ _1F_1 \left( k + 0.5, k + 1, -\frac{A_1^2 C_2}{\sigma^2} \varepsilon_l \right)
\]  

(42)
C. Three Reflectors, $L = 3$

Similar to the $L = 2$ case, the SER for $L = 3$ can be computed as,

$$
\bar{P}_e = C_1 \int_{B_{3,m}}^{B_{3,M}} Q\left(b_3\sqrt{\frac{C_2}{\sigma_z^2}}\right) f_{B_3}(b_3) db_3
$$

where $B_{3,m}$ and $B_{3,M}$ the minimum and maximum values of $B_3$. As can be noted from (27), evaluating $\bar{P}_e$ in closed-form is infeasible because $f_{B_3}(b_3)$ does not have a closed-form solution. Consequently, the SER can be obtained numerically after substituting (27) into (43).

D. Number of Reflectors $L \geq 4$

Because $B_{L,m} \leq B_L \leq B_{L,M}$, then $Y_L = B_L^2$ is bounded as $B_{L,m}^2 \leq Y_L \leq B_{L,M}^2$. Therefore,

$$
\bar{P}_e = \int_{B_{L,m}^2}^{B_{L,M}^2} P_e f_{Y_L}(y_L)dy_L
$$

$$
= \frac{C_1}{\sqrt{2\pi\sigma_{Y_L}^2}} \int_{B_{L,m}^2}^{B_{L,M}^2} Q\left(\frac{C_2}{\sigma_z^2}y_L\right) \exp\left(-\frac{(y_L - \mu_{Y_L})^2}{2\sigma_{Y_L}^2}\right) dy_L.
$$

To be able to solve the integral, the Q-function approximation is used [68], and thus

$$
\bar{P}_e = \frac{1.135\pi\sqrt{2\sigma_{Y_L}^2}}{C_1 \exp\left(-\frac{\mu_{Y_L}^2}{2\sigma_{Y_L}^2}\right)} \sum_{i=1}^{n_a} (-1)^{i+1} \frac{1.98^i}{i! 2^{i+\frac{1}{2}}} \left(\frac{C_2}{\sigma_z^2}\right)^{i+\frac{1}{2}}
$$

$$
\times \int_{B_{L,m}^2}^{B_{L,M}^2} y_L^{i-\frac{1}{2}} \exp\left(-\frac{y_L^2}{2\sigma_{Y_L}^2} + \frac{\mu_{Y_L}^2}{2\sigma_{Y_L}^2} - \frac{C_2^2}{2\sigma_z^2}\right) dy_L
$$

The integral in (45) can be solved recursively [67, 1.3.3.19, pp. 140], and the solution is given in terms of the error function or $Q$-function. However, when $B_{L,m}^2 \rightarrow 0$ and $B_{L,M}^2 \rightarrow \infty$, $\bar{P}_e$ can be given as [67, 2.3.15.3, pp. 343]

$$
\bar{P}_e = Z \sum_{i=1}^{n_a} (-1)^{i+1} \frac{1.98^i}{i! 2^{i+\frac{1}{2}}} \Gamma\left(i + \frac{1}{2}\right) \left(\frac{\sigma_{Y_L}}{2\sigma_z^2}\right)^\frac{i}{2} D_{-\left(i+\frac{1}{2}\right)}\left(\frac{C_2}{2\sigma_z^2} - \frac{\mu_{Y_L}}{\sigma_{Y_L}^2}\right)
$$

where

$$
Z = \frac{C_1 \sigma_z}{2 \times 1.135\pi \sqrt{C_2 \sigma_{Y_L}}} \exp\left(\frac{\sigma_{Y_L}^2}{4} \left(\frac{\mu_{Y_L}}{\sigma_{Y_L}^2} - \frac{C_2}{2\sigma_z^2}\right)^2 - \frac{\mu_{Y_L}^2}{2\sigma_{Y_L}^2}\right)
$$

and $D(\cdot) (\cdot)$ is the parabolic cylinder function.
V. Outage Probability Analysis

For the case of \( L = 1 \), the channel gain is fixed, and thus, the outage process depends only on the signal power. For the remaining cases, i.e., \( L = 2, L = 3 \) and \( L \geq 4 \), the derivation of the outage probability is presented below.

A. Two Reflectors, \( L = 2 \)

Given that the instantaneous SNR threshold \( \gamma_O \triangleq \frac{b_O^2}{\sigma_z^2} \), then the envelope threshold \( b_O = \sqrt{\sigma_z^2 \gamma_O} \).

Therefore, the outage probability can be derived as

\[
\bar{P}_O = \begin{cases} 
\int_{B_{2,m}}^{b_O} f_{B_2}(b_2) db_2, & b_O > B_{2,m} \\
1, & b_O \leq B_{2,m}
\end{cases}
\] (48)

where \( \bar{P}_O|_{b_O > B_{2,m}} \) can be computed as

\[
\bar{P}_O = \frac{2}{\pi I_0^{(2)}(\kappa)} \int_{B_{2,m}}^{b_O} b_2 I_0 \left[ \frac{\sqrt{(\kappa_1 - \kappa_2)^2 + \frac{\kappa_2 \kappa_1}{A_1 A_2} (b_2^2 - A_2)}}{\sqrt{(A_3 - b_2^2) (b_2^2 - A_2)}} \right] db_2
\] (49)

substituting \( x = \sqrt{b_2^2 - A_2} \) and noting that \( B_{2,m}^0 = A_2 \) gives \( dx = b/x db \)

\[
\bar{P}_O = \frac{2}{\pi I_0^{(2)}(\kappa)} \int_0^{b_O - A_2} I_0 \left[ \frac{\sqrt{(\kappa_1 - \kappa_2)^2 + \frac{\kappa_2 \kappa_1}{A_1 A_2} x^2}}{\sqrt{-x^2 + A_2^2}} \right] dx.
\] (50)

Using the infinite series representation of the Bessel function gives

\[
\bar{P}_O = \frac{2}{\pi I_0^{(2)}(\kappa)} \sum_{m=0}^{\infty} \frac{1}{2^{2m} (m!)^2} \int_0^{b_O - A_2} \left( \frac{(\kappa_1 - \kappa_2)^2 + \frac{\kappa_2 \kappa_1}{A_1 A_2} x^2}{\sqrt{-x^2 + A_2^2}} \right)^m dx.
\] (51)

Then, by applying the binomial series expansion,

\[
\bar{P}_O = \frac{2}{\pi I_0^{(2)}(\kappa)} \sum_{m=0}^{\infty} \frac{1}{2^{2m} (m!)^2} \sum_{l=0}^{m} \binom{m}{l} (\kappa_1 - \kappa_2)^{2(m-l)} \frac{\kappa_2 \kappa_1}{A_1 A_2} \int_0^{b_O - A_2} \frac{x^{2l}}{\sqrt{-x^2 + A_2^2}} dx
\] (52)

which can be solved using [67, 1.2.48.8, pp. 97] as

\[
\bar{P}_O = \frac{2}{\pi I_0^{(2)}(\kappa)} \sum_{m=0}^{\infty} \frac{1}{2^{2m} (m!)^2} (\bar{P}_O|_{l=0} + \bar{P}_O|_{l \geq 1})
\] (53)
where $P_O|_{l=0} = (\kappa_1 - \kappa_2)^2 m \arcsin\left(\frac{B_O}{A_1}\right)$, $B_O = \sqrt{b_o^2 - A_2}$, and

$$P_O|_{l\geq 1} = \sum_{l=1}^{m} \binom{m}{l} (\kappa_1 - \kappa_2)^{2(m-l)} \left(\frac{\kappa_2 \kappa_1}{A_1 A_2}\right)^l \left\{ \begin{array}{l} B_O^{2l-1} + \sum_{k=1}^{l-1} H_{k,l} A_1^{2k} B_O^{2l-2k-1} \\ \times -\frac{1}{2l} \sqrt{A_1^2 - B_O^2 + \frac{A_1^{2l}(2l-1)!!}{2l!}} \arcsin\left(\frac{B_O}{A_1}\right) \end{array} \right\}$$

where

$$H_{k,l} = (2l - 1)(2l - 3) \cdots (2l - 2k + 1) \frac{2^k}{(l-1)(l-2) \cdots (l-k)}$$

and $(\cdot)!!$ is the double factorial.

**B. Three Reflectors, $L = 3$**

The outage probability for this case can be derived as

$$P_O = \begin{cases} \int_{B_{3,m}}^{b_O} f_{B_3}(b_3) db_3, & b_O > B_{3,m} \\ 1, & b_O \leq B_{3,m} \end{cases}$$

(55)

Similar to the SER, the outage probability for this case will be evaluated numerically because $f_{B_3}(b_3)$ (27) does not have a closed-form representation.

**C. Number of Reflectors $L \geq 4$**

In this case, the PDF obtained using the CLT can be used to derive $P_O$,

$$P_O = \int_{B_{L,m}}^{b_O} f_{Y_L}(y_L) dy_L$$

$$= \frac{1}{\sigma_{Y_L} \sqrt{2\pi}} \int_{B_{L,m}}^{b_O} \exp\left(-\frac{1}{2} \left(\frac{y_L - \mu_{Y_L}}{\sigma_{Y_L}}\right)^2\right) dy_L$$

$$= Q\left(\frac{B_{L,m}^2 - \mu_{Y_L}}{\sigma_{Y_L}}\right) - Q\left(\frac{b_O^2 - \mu_{Y_L}}{\sigma_{Y_L}}\right).$$

(56)

**VI. Numerical Results**

This section presents the numerical results obtained from the derived formulae, and compares them to Monte Carlo simulation results using various configurations. The performance of the considered UAV-IRS system is evaluated in terms of SER and outage probability. Each simulation point is obtained using $10^7$ realizations. The average transmission power for all scenarios is normalized to unity, and the SNR in dB is defined as $\text{SNR} \triangleq -\log_{10}(\sigma_z^2)$. The phase estimates are considered unbiased, i.e., $\mu = 0$, and
Fig. 3: Analytical and simulated SER and outage probability of the system for various number of reflecting elements $L$, where $\kappa = 20$, and $A_i = 1 \ \forall i$.

$\kappa_i = \kappa \ \forall i$ is considered for all figures. For the outage probability, the SNR threshold has been set at $\gamma_O = 10 \text{ dB}$ for all scenarios. The modulation used is binary phase shift keying (BPSK), and hence, the SER and bit error rate (BER) are equal. The analytical SER results for $L = 2$ are obtained using (38) and (42) for equal and unequal received signal amplitudes, respectively. On the other hand, the outage probability for $L = 2$ is obtained using (54). Unless it is specified otherwise, the SER and outage probabilities for $L = 3$ are obtained using (43) and (55), respectively. For $L \geq 4$, the SER is obtained using (46) and the outage probability is obtained using (56). In all infinite summations, we consistently use the first 30 terms.

Fig. 3 shows the analytical and simulated SER and outage probability of the considered system for various values of $L$ where $\kappa = 20$, and $A_i = 1 \ \forall i$. As can be noted from Fig. 3a, the derived SER expressions match very well the simulation results, including the SER case for $L \geq 4$, which is derived based on the CLT. In addition, the results show the considerable SER enhancement caused by using IRSs. However, the obtained SNR gain decreases as $L$ increases. For example, the SNR gain is about 6 dB using $L = 10$ as compared to $L = 20$, while the gain is only 3.5 dB when increasing $L$ from 20 to 30. The same behavior is obtained for $L = 1, 2, 3$.

Fig. 3b shows the outage probability of the system where the SNR threshold $\gamma_O = 10 \text{ dB}$. According
to the figure, a perfect match between simulations and analysis is obtained for $L \leq 3$ and $L \geq 20$. However, for the remaining cases, i.e., $4 \leq L < 20$, a small mismatch can be noted when $P_O$ is below $10^{-3}$. The small difference is due to the CLT, which becomes more accurate by increasing $L$. Moreover, it can be observed that using IRSs can significantly enhance the outage probability. Nevertheless, the outage probability curves are very steep at high values of $L$ because the received signal power distribution is very narrow, and thus, small SNR changes may cause significant change in the outage probability.

Fig. 4 shows the analytical and simulated system SER and outage probability for various values of $L$ and two cases for $A_i$. In case 1, $A_i = 1 \forall i$, and in Case 2, $\{A_1, A_2, A_3\} = \{5, 3, 2\}$ and $A_4, A_5, \ldots, A_{30} = 1$. For all cases in the figure $\kappa = 20$. As can be noted from Fig. 4a, the SER analytical results match very well the simulation results for all the considered scenarios. The results are presented for the unequal amplitudes as well to evaluate the impact of the signal amplitude on $\bar{P}_e$. For example, for the case of $L = 1$ with $A_1 = 5$ has approximately 5 dB improvement over the case of $L = 3$ with $\{A_1, A_2, A_3\} = 1$. This implies that the link quality has a significant effect on the system performance in addition to the number of reflectors $L$. Fig. 4b shows the outage probability. As can be observed from the figure, the obtained analysis perfectly matches the simulation results. The figure also
Fig. 5: SER and outage probability for various values of \( \kappa \) and \( L \) using \( A_i = 1 \ \forall i \).

shows that the outage probability is inversely proportional to the link quality.

Fig. 5a shows the SER for different values of \( \kappa \) and \( L \) using \( A_i = 1 \ \forall i \). The SER of \( L = 1 \) is used as a benchmark, and its is not affected by \( \kappa \) since the receiver is assumed to know the overall signal phase accurately. For the theoretical results. As can be noted from the figure, the analysis matches the simulation results for all cases except for \( L = 3 \) with \( \kappa \leq 5 \), where some mismatch is resulted from the multiple discontinuities in \( b_3^2 \) that appear at low \( \kappa \) values. It can be also noted that large values of \( \kappa \) correspond to small phase errors, and thus, better SER. The figure also shows that the SER degradation versus \( \kappa \) depends on \( L \). For small values of \( L \) the SER is very sensitive to the variations of \( \kappa \). Therefore, increasing the number of reflectors is an efficient approach to mitigate the phase errors. The same observations and conclusions can be generally made for the outage probability in Fig. 5b.

Fig. 6 shows the SER and outage probability for various values of \( L \), \( A_i = 1 \ \forall i \), and \( \kappa = 5 \). All the results in the figure are obtained using the CLT given in (46) and (56) for the SER and outage probability, respectively. As can be noted from Fig. 6a, the simulation results deviate significantly from the theoretical results obtained using CLT when \( L < 4 \). However, the mismatch decreases for \( L \geq 4 \) and becomes negligible for \( L \geq 6 \). Therefore, the accurate analysis for the cases of \( L = 2 \) and \( 3 \) is necessary to provide accurate analytical results for such cases. The outage probability results in Fig. 6b show a higher deviation between the simulation and analytical results obtained using the CLT, particularly for
Fig. 6: The SER and outage probability for different values of $L$, where the CLT is applied for all $L$, and $\kappa = 5$.

$L < 10$. Moreover, it can be noted that the deviation becomes more apparent for $\bar{P}_O < 10^{-3}$.

Fig. 7 is produced using the same settings of Fig. 6 except that $\kappa = 20$. As can be noted from Fig. 7a, the CLT in this case gives near perfect match even for $L = \{1, 2, 3\}$. Such performance is obtained because at high values of $\kappa$ the PDF of the envelope becomes mostly concentrated around $B_{L,M}$, and hence, averaging the conditional SER over the PDF will be mostly dependent on the mean and variance of the PDF rather than the actual shape of the PDF. For the outage probability the scenario is different because outage computation involves integration over the PDF itself with no averaging operation. Therefore, it can be noted from the results in Fig. 7b the CLT does not provide accurate results for $L < 10$.

Fig. 8 shows the SER versus SNR for the cases where the signals have fixed and random amplitudes. For the random amplitudes, the fading factor is modeled as Rician distribution with parameters $\Omega$ and $\mathcal{K}$ i.e., $A_i \sim \mathcal{R}(\Omega, \mathcal{K})$. For fair comparison, we set $\Omega = 1$ for each of the $L$ signals in the Rician case and $A_i = 1 \ \forall i$ for the fixed amplitudes case. As can be noted from the figure, the SER performance for the Rician model converges to the fixed amplitude model when $L$ or $\mathcal{K}$ increases. For example, it can be noted that $\bar{P}_e| (A_i = 1) \approx \bar{P}_e| (A_i \sim \mathcal{R}(1, 20))$. Moreover, the SNR gain obtained by increasing $\mathcal{K}$
Fig. 7: The SER and outage probability for different values of $L$, where the CLT is applied for all $L$, and $\kappa = 20$.

Fig. 8: The SER for Rician distributed amplitudes, i.e., $A_i \sim \mathcal{R}(\Omega, \kappa)$. 
becomes less important as \( L \) increases. For example, at \( \bar{P}_e = 10^{-5} \), the SNR gain obtained by increasing \( K \) from 5 to 20 dB is 27 dB when \( L = 2 \), while it is almost 4 dB when \( L = 20 \).

VII. CONCLUSION

The SER and outage performance of IRS assisted UAV-UAV communications were investigated when phase compensation at the reflectors is imperfect. The derivations for the SER and outage probability were provided for \( L = \{1, 2, 3\} \) using SAT, and CLT when \( L \geq 4 \). The results provided an insight on the interplay between the number of elements, phase errors and system performance. It was demonstrated that IRS significantly improve the performance of UAV-UAV communications, particularly for large values of \( L \). More interestingly however, it was shown that increasing the number of reflectors provides some form of immunity against phase error. On the other hand, when \( L \) is small, the degradation due to large phase errors may surpass the IRS gain, hence it is paramount that the system designer is aware of the amount of phase error. In addition, the results revealed that the accuracy of the CLT approximation improves as \( L \) and \( \kappa \) increase. Finally, it was found that the nonfading amplitudes model can be used to accurately model the fading amplitudes with Rician fading given that the Rician factor, or the number of reflectors, is large.

APPENDIX I

The expected value of \( \cos(n\phi_j) \) can be expressed as

\[
E[\cos(n\phi_j)] = \frac{1}{2\pi I_0(\kappa_j)} \int_{-\pi}^{\pi} \cos(n\phi_j) e^{\kappa_j \cos(\phi_j)} d\phi_j
\]

By dividing the interval of the integral into two subintervals, \([−\pi, 0]\) and \((0, \pi]\), \(E[\cos(n\phi_j)]\) and substituting \(\theta = \phi_j\) in the first integral, and noting that \(\cos(-\theta) = \cos \theta\) yields

\[
E[\cos(n\phi_j)] = \frac{1}{2\pi I_0(\kappa_j)} \left( -\int_{-\pi}^{0} \cos(n\theta) e^{\kappa_j \cos(\theta)} d\theta + \int_{0}^{\pi} \cos(n\phi_j) e^{\kappa_j \cos(\phi_j)} d\phi_j \right)
\]

\[
= \frac{1}{2\pi I_0(\kappa_j)} \left( \int_{0}^{\pi} \cos(n\theta) e^{\kappa_j \cos(\theta)} d\theta + \int_{0}^{\pi} \cos(n\phi_j) e^{\kappa_j \cos(\phi_j)} d\phi_j \right)
\]

\[
= \frac{1}{\pi I_0(\kappa_j)} \int_{0}^{\pi} \cos(n\phi_j) e^{\kappa_j \cos(\phi_j)} d\phi_j
\]

Consequently, the definition of the modified Bessel function can be used,

\[
I_n(x) = \frac{1}{\pi} \int_{0}^{\pi} \cos(n\theta) e^{x \cos(\theta)} d\theta
\]
and thus, $E[\cos(n\phi_j)]$ can be written as

$$E[\cos(n\phi_j)] = \frac{I_n(\kappa_j)}{I_0(\kappa_j)}. \quad (60)$$

On the other hand, the expected value of $\cos(n\phi_j)$ can be expressed as

$$E[\sin(n\phi_j)] = \frac{1}{2\pi} \int_{-\pi}^{\pi} \sin(n\phi_j) e^{\kappa_j \cos(\phi_j)} d\phi_j$$

$$= \frac{1}{2\pi I_0(\kappa_j)} \left( \int_{-\pi}^{0} \sin(n\phi_j) e^{\kappa_j \cos(\phi_j)} d\phi_j + \int_{0}^{\pi} \sin(n\phi_j) e^{\kappa_j \cos(\phi_j)} d\phi_j \right)$$

$$= 0 \quad (61)$$

where the last equality is obtained by substituting $\theta = -\phi_j$ and noting that $\sin(-\theta) = -\sin \theta$ while $\cos(-\theta) = \cos \theta$.

**APPENDIX II**

The values of $\mu_{y_L}$ and $\sigma^2_{y_L}$ can be derived as the following

$$\mu_y = E[B_L^2]$$

$$= E[A^2] + 2 \sum_{L \geq j > k \geq 1} E[A_j A_k \cos(\phi_j - \phi_k)]$$

$$= \sum_{i=1}^{L} E[A_i^2] + 2 \sum_{L \geq j > k \geq 1} E[A_j] E[A_k] E[\cos(\phi_j - \phi_k)] \quad (62)$$

After some mathematical manipulations and given $A_i \forall i$ is fixed, then $\mu_y$ can be computed as

$$E[Y_L] = \sum_{i=1}^{L} A_i^2 + 2 \sum_{L \geq j > k \geq 1} A_j A_k (E[\cos \phi_j] E[\cos \phi_k] + E[\sin \phi_j] E[\sin \phi_k])$$

$$= \sum_{i=1}^{L} A_i^2 + 2 \sum_{L \geq j > k \geq 1} A_j A_k \frac{I_1(\kappa_j) I_1(\kappa_k)}{I_0(\kappa_j) I_0(\kappa_k)}. \quad (63)$$

The variance $\sigma^2_{y_L}$ can be computed as

$$\sigma^2_{y_L} \triangleq E[Y_L^2] - E^2[Y_L]$$

$$= E[Y_L^2] - \left( \sum_{i=1}^{L} A_i^2 + 2 \sum_{L \geq j > k \geq 1} A_j A_k \frac{I_1(\kappa_j) I_1(\kappa_k)}{I_0(\kappa_j) I_0(\kappa_k)} \right) \quad (64)$$
where

\[
E \left[ Y_L^2 \right] = E \left[ \left( |A|^2 + 2 \sum_{L \geq j > k \geq 1} A_j A_k \cos (\phi_j - \phi_k) \right)^2 \right]
\]

\[
= \left( |A|^2 \right)^2 + 4E \left[ \left( \sum_{L \geq j > k \geq 1} A_j A_k \cos (\phi_j - \phi_k) \right)^2 \right] + 4|A|^2 \sum_{L \geq j > k \geq 1} A_j A_k E [\cos (\phi_j - \phi_k)]
\]

(65)

where the term \( T_2 \) can be derived as

\[
T_2 = 4|A|^2 \sum_{L \geq j > k \geq 1} A_j A_k E [\cos (\phi_j - \phi_k)]
\]

(66)

\[
= 4|A|^2 \sum_{L \geq j > k \geq 1} A_j A_k \frac{I_1 (\kappa_j)}{I_0 (\kappa_j)} \frac{I_1 (\kappa_k)}{I_0 (\kappa_k)}
\]

(67)

The term \( T_1 \) can be derived as

\[
T_1 = 4E \left[ \left( \sum_{n \geq j > k \geq 1} A_j A_k \cos (\phi_j - \phi_k) \right)^2 \right]
\]

\[
= 4 \sum_{L \geq j > k \geq 1} A_j^2 A_k^2 E [\cos^2 (\phi_j - \phi_k)] + 8 \sum_{L \geq j > k \geq 1} \sum_{L \geq i > l > 1} A_j A_k A_i A_l E [\cos (\phi_j - \phi_k)] E [\cos (\phi_i - \phi_l)]
\]

\[
\]

(69)

The term \( T_{1,1} \) is given by

\[
T_{1,1} = 4 \sum_{L \geq j > k \geq 1} A_j^2 A_k^2 E [\cos^2 (\phi_j - \phi_k)]
\]

\[
= 2 \sum_{L \geq j > k \geq 1} A_j^2 A_k^2 (1 + E [\cos (2\phi_j - 2\phi_k)])
\]

\[
= 2 \sum_{L \geq j > k \geq 1} A_j^2 A_k^2 (1 + E [\cos (2\phi_j) \cos (2\phi_k) + \sin (2\phi_j) \sin (2\phi_k)])
\]

\[
= 2 \sum_{L \geq j > k \geq 1} A_j^2 A_k^2 \left( 1 + \frac{I_2 (\kappa_j) I_2 (\kappa_k)}{I_0 (\kappa_j) I_0 (\kappa_k)} \right)
\]

(70)

(71)
The term $T_{1,2}$ is

$$T_{1,2} = 8 \sum_{L \geq j > k \geq 1} \sum_{L \geq i > l > 1} A_j A_k A_i A_l E \left[ \cos \left( \phi_j - \phi_k \right) \right] E \left[ \cos \left( \phi_i - \phi_l \right) \right]$$

$$= 8 \sum_{L \geq j > k \geq 1} \sum_{L \geq i > l > 1} A_j A_k A_i A_l \frac{I_1 \left( \kappa_j \right) I_1 \left( \kappa_k \right) I_1 \left( \kappa_i \right) I_1 \left( \kappa_l \right)}{I_0 \left( \kappa_j \right) I_0 \left( \kappa_k \right) I_0 \left( \kappa_i \right) I_0 \left( \kappa_l \right)}. \quad (72)$$
