ON THE SYMMETRIC DETERMINANTAL REPRESENTATIONS
OF THE FERMAT CURVES OF PRIME DEGREE

YASUHIRO ISHITSUKA AND TETSUSHI ITO

Abstract. We prove that the defining equations of the Fermat curves of prime degree cannot be written as the determinant of symmetric matrices with entries in linear forms in three variables with rational coefficients. In the proof, we use a relation between symmetric matrices with entries in linear forms and non-effective theta characteristics on smooth plane curves. We also use some results of Gross-Rohrlich on the rational torsion points on the Jacobian varieties of the Fermat curves of prime degree.

1. Introduction

Let us consider the following Diophantine problem motivated by the Arithmetic Invariant Theory of symmetrized $3 \times n \times n$ boxes ([3], [14]): for a smooth plane curve $C \subset \mathbb{P}^2_K$ of degree $n \geq 1$ defined over a field $K$, does there is a triple of symmetric matrices $(M_0, M_1, M_2)$ of size $n$ with entries in $K$ such that $C$ is defined by the equation of the form

$$\det (X_0M_0 + X_1M_1 + X_2M_2) = 0?$$

If $C$ is defined by the above equation, we say $C$ admits a symmetric determinantal representation over $K$. We say two symmetric determinantal representations of $C$ defined by triples $(M_0, M_1, M_2), (M'_0, M'_1, M'_2)$ are equivalent if there are $P \in \text{GL}_n(K)$ and $a \in K^\times$ with $M'_i = a^t P M_i P$ for $i = 0, 1, 2$, where $^t P$ is the transpose of the matrix $P$. Note that equivalent triples give the same plane curve because we have

$$\det (X_0M'_0 + X_1M'_1 + X_2M'_2) = \det (X_0(a^t P M_0 P) + X_1(a^t P M_1 P) + X_2(a^t P M_2 P)) = a^n \cdot (\det P)^2 \cdot \det (X_0M_0 + X_1M_1 + X_2M_2).$$

Finding symmetric determinantal representations of plane curves is a classical problem in algebraic geometry. For the history of this problem and known results, see [6], [8], [6], [26], [2], [7] Ch 4. When $K$ is algebraically closed of characteristic zero, all plane curves (including singular ones) admit symmetric determinantal representations ([2] Remark 4.4). When $K$ is not algebraically closed, many plane curves do not admit symmetric determinantal representations over $K$. In [10], [17], we studied the local-global principle for the existence of symmetric determinantal representations over global fields.

In this paper, we study symmetric determinantal representations of the Fermat curves of prime degree and the Klein quartic over the field $\mathbb{Q}$ of rational numbers.

Key words and phrases. plane curve, Fermat curves, determinantal representation, theta characteristic.
We prove that the Fermat curves of prime degree do not admit symmetric determinantal representations over \( \mathbb{Q} \).

**Theorem 1.1.** Let \( p \geq 2 \) be a prime number. The Fermat curve of degree \( p \)
\[
F_p := (X_0^p + X_1^p + X_2^p = 0) \subset \mathbb{P}^2_\mathbb{Q}
\]
does not admit a symmetric determinantal representation over \( \mathbb{Q} \).

**Remark 1.2.** Theorem 1.1 can be rephrased in concrete terms as follows: there do not exist symmetric matrices \( M_0, M_1, M_2 \) of size \( p \) with entries in \( \mathbb{Q} \) and \( a \in \mathbb{Q}^\times \) satisfying
\[
X_0^p + X_1^p + X_2^p = a \cdot \det (X_0M_0 + X_1M_1 + X_2M_2).
\]
Since it is a Diophantine problem with \( 3p^2 + 1 \) variables, it seems difficult to prove the non-existence of solutions in \( \mathbb{Q} \) directly. We shall prove Theorem 1.1 using the methods and the results from algebraic geometry.

**Remark 1.3.** The Fermat curves are sometimes defined by the equation \( X_0^p + X_1^p = X_2^p \) instead of \( X_0^p + X_1^p + X_2^p = 0 \). There is no essential difference when \( p \) is odd. But there is a difference when \( p = 2 \). In fact, the smooth conic \( (X_0^2 + X_1^2 = X_2^2) \) admits a symmetric determinantal representation over \( \mathbb{Q} \). (See Remark 2.7.)

The strategy of the proof of Theorem 1.1 is as follows. The case of \( p = 2 \) is easy and treated separately. Let \( p \geq 3 \) be an odd prime number. For a smooth plane curve \( C \subset \mathbb{P}^2_\mathbb{Q} \) over \( \mathbb{Q} \), triples of symmetric matrices giving rise to symmetric determinantal representations correspond to certain line bundles on \( C \) called non-effective theta characteristics (Proposition 2.2). Therefore, in order to prove Theorem 1.1 we have to prove the non-existence of non-effective theta characteristics on \( F_p \) over \( \mathbb{Q} \). If \( \mathcal{L} \) is a non-effective theta characteristic on \( F_p \) over \( \mathbb{Q} \), the line bundle \( \mathcal{L} \otimes \Theta_{F_p}((-p + 3)/2) \) gives a non-trivial \( \mathbb{Q} \)-rational 2-torsion point on the Jacobian variety \( \text{Jac}(F_p) \). For an integer \( s \) with \( 1 \leq s \leq p - 2 \), let \( C_s \) be the projective smooth model of the affine curve
\[
V^p = U(1 - U)^s.
\]
Gross-Rohrlich calculated the \( \mathbb{Q} \)-rational torsion points on \( \text{Jac}(C_s) \) ([12]). There is an isogeny
\[
\prod_{1 \leq s \leq p - 2} \text{Jac}(C_s) \longrightarrow \text{Jac}(F_p)
\]
defined over \( \mathbb{Q} \) whose degree is a power of \( p \). We can calculate the \( \mathbb{Q} \)-rational 2-torsion points on \( \text{Jac}(F_p) \) (Corollary 3.4). When \( p \neq 7 \), we have the non-existence of non-effective theta characteristics on \( F_p \) over \( \mathbb{Q} \). The case of \( p = 7 \) requires a little care because there are three non-trivial \( \mathbb{Q} \)-rational 2-torsion points on \( \text{Jac}(F_7) \). In fact, we have
\[
\text{Jac}(F_7)[2](\mathbb{Q}) \cong (\mathbb{Z}/2\mathbb{Z})^2.
\]
Fortunately, by explicit calculation, we can prove these 2-torsion points correspond to effective theta characteristics on \( F_7 \) over \( \mathbb{Q} \). Hence non-effective theta characteristics on \( F_7 \) over \( \mathbb{Q} \) do not exist. (The calculation of \( \mathbb{Q} \)-rational \( p \)-torsion points on \( \text{Jac}(F_p) \) is more subtle ([23], [24], [25]). We do not need these results in this paper.)

Along the proof of Theorem 1.1 we also study symmetric determinantal representations of the *Klein quartic*
\[
C_{Kl} := (X_0^3X_1 + X_1^3X_2 + X_2^3X_0 = 0) \subset \mathbb{P}^2_\mathbb{Q}
\]
over $\mathbb{Q}$. It was already known to Klein that $C_{Kl}$ admits a symmetric determinantal representation over $\mathbb{Q}$. In fact, it is easy to confirm the following equality (cf. [9, p. 161]):

\begin{equation}
X_0^3X_1 + X_1^3X_2 + X_2^3X_0 = -\det \begin{pmatrix}
X_0 & 0 & 0 & -X_1 \\
0 & X_1 & 0 & -X_2 \\
0 & 0 & X_2 & -X_0 \\
-X_1 & -X_2 & -X_0 & 0
\end{pmatrix}
\end{equation}

We prove that the above expression gives a unique equivalence class of symmetric determinantal representations of $C_{Kl}$ over $\mathbb{Q}$.

**Theorem 1.4.** There is a unique equivalence class of symmetric determinantal representations of the Klein quartic $C_{Kl}$ over $\mathbb{Q}$.

The proof of Theorem 1.4 is as follows. It is classically known that $C_{Kl}$ is birational over $\mathbb{Q}$ to the curve $C_2$ (or $C_4$) for $p = 7$ studied by Gross-Rohrlich ([10, p. 67]). Using the results of Gross-Rohrlich, we see that $\text{Jac}(C_{Kl})[2](\mathbb{Q}) \cong \mathbb{Z}/2\mathbb{Z}$. Hence there are exactly two theta characteristics on $C_{Kl}$ over $\mathbb{Q}$, up to isomorphism.

**Remark 1.5.** There is a long history on the study of the Klein quartic. There is no surprise if some geometers have expected (or presumed) that Theorem 1.4 could be true. Note that a rigorous proof of Theorem 1.4 requires the study of the field of definition of equivalence classes of symmetric determinantal representations, which is a slightly delicate arithmetic problem. (See Corollary 2.3 (4). See also [14], [15].) These days, we become more interested in the arithmetic properties of linear orbits related to symmetric determinantal representations thanks to the recent developments of Arithmetic Invariant Theory ([14], [3]).

In Section 2, we recall a relation between symmetric determinantal representations and non-effective theta characteristics. Theorem 1.1 for $p = 2$ is a consequence of the fact that the conic ($X_0^2 + X_1^2 + X_2^2 = 0$) has no $\mathbb{Q}$-rational points. In Section 3, we recall some results of Gross-Rohrlich, and prove Theorem 1.1 for $p \neq 2, 7$. The proof of Theorem 1.1 for $p = 7$ is given in Section 4. Finally, the proof of Theorem 1.4 is given in Section 5.

## 2. Theta Characteristics and Symmetric Determinantal Representations

Let $K$ be a field, and $C \subset \mathbb{P}^2_K$ a smooth plane curve of degree $n \geq 1$. The genus of $C$ is equal to $g(C) := (n - 1)(n - 2)/2$. 
**Definition 2.1** (20).  
(1) A **theta characteristic** on $C$ is a line bundle $\mathcal{L}$ on $C$ satisfying $\mathcal{L} \otimes \mathcal{L} \cong \Omega^1_C$, where $\Omega^1_C$ is the canonical sheaf on $C$.

(2) A theta characteristic $\mathcal{L}$ on $C$ is **effective** (resp. **non-effective**) if $H^0(C, \mathcal{L}) \neq 0$ (resp. $H^0(C, \mathcal{L}) = 0$).

**Proposition 2.2.** There is a bijection between the set of isomorphism classes of non-effective theta characteristics on $C$ and the set of equivalence classes of symmetric determinantal representations of $C$ over $K$.

**Proof.** This proposition is well-known when $\text{char } K \neq 2$ (2. Proposition 6.23], 2. Proposition 4.2], 7. Ch 4], 13. Theorem 4.12]). It is not difficult to modify the arguments in 2] to cover the case of characteristic two (2. Remark 2.2]). For a proof of this proposition which works over arbitrary fields, see also [15]. □

In order to study the field of definition of equivalence classes of symmetric determinantal representations, we use the Picard scheme and the Jacobian variety of the smooth plane curve $C$ (4, 18). Let us recall their basic properties. The **Picard group**

$$\text{Pic}(C) := H^1(C, \mathcal{O}_C^\times)$$

is the group of isomorphism classes of line bundles on $C$. Let $\text{Pic}_{C/K}$ be the **Picard scheme** of $C$ representing the relative Picard functor ([4. Theorem 3 in §8.2]). We have the following exact sequence

$$0 \longrightarrow \text{Pic}(C) \longrightarrow \text{Pic}_{C/K}(K) \longrightarrow \text{Br}(K),$$

where $\text{Br}(K)$ is the Brauer group of $K$.

The equality $\text{Pic}(C) = \text{Pic}_{C/K}(K)$ holds if $C$ has a $K$-rational point (4. Proposition 4 in §8.1]). The identity component of $\text{Pic}_{C/K}$ is denoted by $\text{Jac}(C)$ called the **Jacobian variety** of $C$. It is known that $\text{Jac}(C)$ is an abelian variety over $K$ of dimension $g(C) = (n - 1)(n - 2)/2$ (4. Proposition 3 in §9.2]).

Let $\text{Pic}(C)[2]$ be the group of 2-torsion points on $\text{Pic}(C)$, which is the group of isomorphism classes of line bundles $\mathcal{L}$ with $\mathcal{L} \otimes \mathcal{L} \cong \mathcal{O}_C$. The group of $K$-rational 2-torsion points on $\text{Jac}(C)$ is denoted by $\text{Jac}(C)[2](K)$. It is always true that $\text{Pic}(C)[2]$ is a subgroup of $\text{Jac}(C)[2](K)$. These two groups are not necessarily equal if $C$ has no $K$-rational points.

Using Proposition 2.2 and the following corollary, we give an upper bound of the number of equivalence classes of symmetric determinantal representations.

**Corollary 2.3.**  
(1) The number of isomorphism classes of theta characteristics on $C$ is less than or equal to the order of $\text{Jac}(C)[2](K)$.

(2) If $C$ has a $K$-rational point, the number of isomorphism classes of theta characteristics on $C$ is zero or equal to the order of $\text{Jac}(C)[2](K)$.

(3) The number of equivalence classes of symmetric determinantal representations of $C$ over $K$ is finite.

(4) Let $L/K$ be an extension of fields. Two symmetric determinantal representations of $C$ over $K$ are equivalent over $K$ if and only if they are equivalent over $L$.

**Proof.** (1) Assume that there is a theta characteristic $\mathcal{L}$ on $C$. The other theta characteristics on $C$ are of the form $\mathcal{L} \otimes \mathcal{L}'$, where $\mathcal{L}'$ is a line bundle on $C$ with $\mathcal{L}' \otimes \mathcal{L}' \cong \mathcal{O}_C$. Hence the number of isomorphism classes of theta characteristics
on $C$ is equal to the order of $\text{Pic}(C)[2]$, which is less than or equal to the order of $\text{Jac}(C)[2](K)$ because $\text{Pic}(C)[2]$ is a subgroup of $\text{Jac}(C)[2](K)$.

(2) If $C$ has a $K$-rational point, we have $\text{Pic}(C)[2] = \text{Jac}(C)[2](K)$, and the assertion (2) follows.

(3) Since $\text{Jac}(C)[2](K)$ is a finite group, the assertion (3) follows.

(4) Since $(\text{Pic}_{C/K}[2] \otimes_K L = \text{Pic}_{C \otimes_K L/L}(L)$. The map $\text{Pic}_{C/K}(K) \rightarrow \text{Pic}_{C \otimes_K L/L}(L)$ is injective. Hence $\text{Pic}(C) \rightarrow \text{Pic}(C \otimes_K L)$ is also injective, and the assertion (4) follows.

□

Remark 2.4. If we define the notion of theta characteristics on singular plane curves as in [21], Proposition 2.2 can be generalized to the case of singular plane curves. There is a natural bijection between equivalence classes of symmetric determinantal representations of $C$ over $K$ and isomorphism classes of non-effective theta characteristics $L$ on $C$ equipped with a certain isomorphism between $L$ and the dual of it ([15]). However, when $C$ has singularities, Corollary 2.3 (3),(4) are not true in general. (See [15] for details.)

Corollary 2.5. Assume that $n \geq 3$ and $n$ is odd. If $\text{Jac}(C)[2](K) = 0$, the smooth plane curve $C$ does not admit a symmetric determinantal representation over $K$.

Proof. By Corollary 2.3 (1), there is at most one isomorphism class of theta characteristics on $C$. By Proposition 2.2, we have only to show that there is an effective theta characteristic on $C$. Since $C \subset \mathbb{P}^2_K$ is a smooth plane curve of degree $n$, the canonical sheaf $\Omega^1_C$ is isomorphic to the restriction $\mathcal{O}_C(n - 3) := \mathcal{O}_{\mathbb{P}^2_K}(n - 3)|_C$ ([13 II., 8.20.3], [19 Exercise 6.4.11]). Hence $\mathcal{O}_C((n - 3)/2) := \mathcal{O}_{\mathbb{P}^2_K}((n - 3)/2)|_C$ is a theta characteristic on $C$. It is effective because homogeneous polynomials in $X_0, X_1, X_2$ of degree $(n - 3)/2$ give global sections of it.

In the following proposition, we consider symmetric determinantal representations of smooth conics. (See also [17, Proposition 5.1])

Proposition 2.6. Assume that $n = 2$. For a smooth conic $C \subset \mathbb{P}^2_K$ over $K$, the following are equivalent.

(1) $C$ is isomorphic to $\mathbb{P}^1_K$ over $K$.

(2) $C$ has a $K$-rational point.

(3) $C$ has a line bundle of odd degree over $K$.

(4) $C$ admits a symmetric determinantal representation over $K$.

If the above conditions are satisfied, there is a unique equivalence class of symmetric determinantal representations of $C$ over $K$.

Proof. (3) $\Rightarrow$ (4) Since the smooth conic $C$ is a projective smooth curve of genus 0, we have $\text{Jac}(C) = 0$ and $\text{Pic}(C) \subset \text{Pic}_{C/K}(K) \cong \mathbb{Z}$. The isomorphism $\text{Pic}_{C/K}(K) \cong \mathbb{Z}$ is given by the degree of line bundles. Since $\deg \Omega^1_C = -2$, $\text{Pic}(C)$ is a subgroup of $\text{Pic}_{C/K}(K)$ of index less than or equal to 2. If $C$ has a line bundle of odd degree over $K$, we have $\text{Pic}(C) = \text{Pic}_{C/K}(K)$, which is a line bundle $L$ of degree $-1$, which
is a non-effective theta characteristic on $C$ over $K$. By Proposition 2.2, $C$ admits a symmetric determinantal representation over $K$.

(4) ⇒ (3) If $C$ admits a symmetric determinantal representation over $K$, there is a non-effective theta characteristic $\mathcal{L}$ on $C$ by Proposition 2.2. We see that $\deg \mathcal{L} = -1$ is odd.

(1) ⇔ (2) ⇔ (3) These implications are well-known. We briefly recall the proof. The implications (1) ⇒ (2) ⇒ (3) are obvious. Assume that $C$ has a line bundle of odd degree. We have $\text{Pic}(C) = \text{Pic}_{C/K}(K) \cong \mathbb{Z}$, and there is a divisor $D$ on $C$ of degree 1. Since the complete linear system $|D|$ is one-dimensional and very ample, $C$ is isomorphic to $\mathbb{P}^1_K$ over $K$ ([13, IV., 3.3.1], [19, Proposition 7.4.1]).

The last assertion follows from Corollary 2.3 (2). □

**Proof of Theorem 1.1 (for $p = 2$).** The smooth conic $(X_0^2 + X_1^2 + X_2^2 = 0)$ has no $\mathbb{Q}$-rational points. It does not admit a symmetric determinantal representation over $\mathbb{Q}$ by Proposition 2.6. □

**Remark 2.7.** The Fermat curves are sometimes defined by the equation

$$X_0^p + X_1^p = X_2^p$$

instead of $X_0^p + X_1^p + X_2^p = 0$. There is no essential difference when $p$ is odd. However, when $p = 2$, the conic $(X_0^2 + X_1^2 = X_2^2)$ is not isomorphic over $\mathbb{Q}$ to the conic $(X_0^2 + X_1^2 + X_2^2 = 0)$. Since the conic $(X_0^2 + X_1^2 = X_2^2)$ has a $\mathbb{Q}$-rational point such as $(1, 0, 1)$, there is a unique equivalence class of symmetric determinantal representations of it over $\mathbb{Q}$ by Proposition 2.6. For example, we have

$$X_0^2 + X_1^2 - X_2^2 = -\det\begin{pmatrix} X_0 + X_2 & X_1 \\ X_1 & -X_0 + X_2 \end{pmatrix}.$$

3. Results of Gross-Rohrlich and the non-existence of symmetric determinantal representations of the Fermat curve of degree $p \neq 7$

We recall some results of Gross-Rohrlich on the $\mathbb{Q}$-rational torsion points on the Jacobian varieties of the Fermat curve of prime degree ([12]).

Let $p \geq 3$ be an odd prime number, and

$$F_p := (X_0^p + X_1^p + X_2^p = 0) \subset \mathbb{P}^2_\mathbb{Q}$$

the Fermat curve of degree $p$ over $\mathbb{Q}$. For an integer $s$ with $1 \leq s \leq p - 2$, let $C_s$ be the projective smooth model of the affine curve

$$V^p = U(1 - U)^s.$$

**Theorem 3.1** (Theorem 1.1 in [12]). Let $\text{Jac}(C_s)(\mathbb{Q})_{\text{tors}}$ be the group of $\mathbb{Q}$-rational torsion points on $\text{Jac}(C_s)$. Then we have

$$\text{Jac}(C_s)(\mathbb{Q})_{\text{tors}} \cong \begin{cases} \mathbb{Z}/p\mathbb{Z} & p \neq 7 \text{ or } (p, s) = (7, 1), (7, 3), (7, 5) \\ \mathbb{Z}/7\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} & (p, s) = (7, 2), (7, 4). \end{cases}$$

Let us calculate the $\mathbb{Q}$-rational prime-to-$p$ torsion points on $\text{Jac}(F_p)$ using Theorem 3.1. There is a finite morphism

$$\varphi_s : F_p \longrightarrow C_s$$
of degree $p$ defined by

$$
\varphi_s(X_0, X_1, X_2) = \left( -\frac{X_0}{X_2} \right)^p, \; (-1)^s+1 X_0 X^s_2 / X^s_2 + 1 \right).
$$

**Remark 3.2.** The above expression may be slightly confusing. The coordinates $(X_0, X_1, X_2)$ of $F_p$ are homogeneous coordinates in the projective plane $\mathbb{P}^2_Q$, whereas the coordinates $(U, V)$ of $C_s$ are affine coordinates. There is a difference of signs from [12, p. 207] because the defining equation of the Fermat curve in [12] is $X^p + Y^p = 1$.

The morphism $\varphi_s$ induces morphisms between Jacobian varieties

$$
\varphi_{s*} : \text{Jac}(F_p) \rightarrow \text{Jac}(C_s), \quad \varphi^* : \text{Jac}(C_s) \rightarrow \text{Jac}(F_p)
$$

corresponding to the pushforward and the pullback of divisor classes. Let $\varphi_s, \varphi^*$ be the product of $\varphi_{s*}, \varphi^*_s$ ($1 \leq s \leq p - 2$), respectively. Faddeev proved that the product $\varphi_s$ induces an isogeny ([11]):

$$
\varphi_s : \text{Jac}(F_p) \rightarrow \prod_{1 \leq s \leq p - 2} \text{Jac}(C_s).
$$

Hence $\varphi^*$ is an isogeny from $\prod_{1 \leq s \leq p - 2} \text{Jac}(C_s)$ to $\text{Jac}(F_p)$.

**Lemma 3.3.** The composite $\varphi^* \circ \varphi_s : \text{Jac}(F_p) \rightarrow \text{Jac}(F_p)$ is equal to the multiplication-by-$p$ isogeny.

**Proof.** This result is presumably well-known ([23, Introduction]). Since it is not stated in [12], we briefly sketch how to deduce it from the results in [12]. It is enough to prove Lemma 3.3 over $\mathbb{Q}$. So we shall work over $\mathbb{Q}$ in the following argument.

Let $\zeta \in \overline{\mathbb{Q}}$ be a primitive $p$-th root of unity. Define the automorphisms $A, B$ of $F_p$ by

$$
A(X_0, X_1, X_2) := (\zeta X_0, X_1, X_2),
$$
$$
B(X_0, X_1, X_2) := (X_0, \zeta X_1, X_2).
$$

Since $\varphi_s : F_p \rightarrow C_s$ is a Galois covering of degree $p$ whose Galois group is generated by $A^{-s}B$, we have

$$
\varphi^* \circ \varphi_s(D) \sim \sum_{s=1}^{p-2} \sum_{j=0}^{p-1} (A^{-s}B)^j D,
$$

for a divisor $D$ on $F_p$ ([12, p. 208]). Here $\sim$ denotes the linear equivalence. It is enough to prove that the difference $\varphi^* \circ \varphi_s(D) - pD$ is a principal divisor for a divisor $D$ on $F_p$ of degree 0.
By a direct calculation, we have

\[
\varphi^* \circ \varphi_*( (a, b, c) ) - p(a, b, c) = \sum_{s=1}^{p-2} \sum_{j=0}^{p-1} (\zeta^{-sj} a, \zeta^j b, c) - p(a, b, c)
\]

= \sum_{1 \leq s, j \leq p-1} (\zeta^{-sj} a, \zeta^j b, c) - \sum_{1 \leq j \leq p-1} (\zeta^j a, \zeta^j b, c) - 2(a, b, c)

= \sum_{1 \leq j, k \leq p-1} (\zeta^k a, \zeta^j b, c) - \sum_{1 \leq j \leq p-1} (\zeta^j a, \zeta^j b, c)

= \sum_{0 \leq j, k \leq p-1} (\zeta^k a, \zeta^j b, c) - \sum_{0 \leq k \leq p-1} (\zeta^k a, \zeta^j b, c) - \sum_{0 \leq j \leq p-1} (a, \zeta^j b, c) - \sum_{0 \leq t \leq p-1} (\zeta^t a, \zeta^t b, c).

Define the rational maps \(\pi_1, \pi_2, \pi_3, \pi_4\) from \(F_p\) to the affine plane by

\[
\pi_1(X_0, X_1, X_2) := \left( (X_0/X_2)^p, (X_1/X_2)^p \right),
\]

\[
\pi_2(X_0, X_1, X_2) := (X_0/X_2)^p, X_1/X_2),
\]

\[
\pi_3(X_0, X_1, X_2) := (X_0/X_2, (X_1/X_2)^p),
\]

\[
\pi_4(X_0, X_1, X_2) := (X_0/X_1, (X_0/X_2)^p).
\]

Then \(\pi_1, \pi_2, \pi_3, \pi_4\) give morphisms from \(F_p\) to the projective smooth models \(C_1, C_2, C_3, C_4\) of the affine curves

\[
U + V + 1 = 0,
\]

\[
U + V^p + 1 = 0,
\]

\[
U^p + V + 1 = 0,
\]

\[
U^{-p}V + V + 1 = 0,
\]

respectively. Note that \(C_1, C_2, C_3, C_4\) are isomorphic to \(\mathbb{P}^1_{\overline{\mathbb{Q}}}\).

The above calculation shows that, for a divisor \(D\) on \(F_p\), we have

\[
\varphi^* \circ \varphi_*(D) - pD \sim \pi_1^* \pi_1*(D) - \pi_2^* \pi_2*(D) - \pi_3^* \pi_3*(D) - \pi_4^* \pi_4*(D),
\]

where \(\pi_i^*\) (resp. \(\pi_{is}\)) denotes the pullback (resp. pushforward) of divisor classes by \(\pi_i\).

Assume that \(\deg D = 0\). For each \(i, \pi_i*(D)\) is a principal divisor because \(\pi_{is}(D)\) is a divisor of degree 0 on \(C_i \cong \mathbb{P}^1_{\overline{\mathbb{Q}}}\). Hence \(\pi_i^* \pi_{is}(D)\) is a principal divisor. We conclude that \(\varphi^* \circ \varphi_*(D) - pD\) is a principal divisor on \(F_p\).

By Lemma 3.3, we have an isomorphism

\[
\text{Jac}(F_p)(\mathbb{Q})_{p^r\text{-tors}} \cong \prod_{1 \leq s \leq p-2} \text{Jac}(C_s)(\mathbb{Q})_{p^r\text{-tors}},
\]

where \(\text{Jac}(F_p)(\mathbb{Q})_{p^r\text{-tors}}\) (resp. \(\text{Jac}(C_s)(\mathbb{Q})_{p^r\text{-tors}}\)) denotes the group of \(\mathbb{Q}\)-rational torsion points on \(\text{Jac}(F_p)\) (resp. \(\text{Jac}(C_s)\)) whose orders are prime to \(p\).

**Corollary 3.4.**

\[
\text{Jac}(F_p)(\mathbb{Q})_{p^r\text{-tors}} \cong \begin{cases} 0 & p \neq 7 \\ (\mathbb{Z}/2\mathbb{Z})^2 & p = 7 \end{cases}
\]
Proof of Theorem 1.1 (for \(p \neq 2, 7\)). There does not exist non-trivial \(\mathbb{Q}\)-rational 2-torsion points on \(\text{Jac}(F_p)\) by Corollary 3.4. Hence \(F_p\) does not admit a symmetric determinantal representation over \(\mathbb{Q}\) by Corollary 2.5.

4. The non-existence of symmetric determinantal representations of the Fermat curve of degree 7

This case requires a little care because we have

\[\text{Jac}(F_7)[2](\mathbb{Q}) \cong (\mathbb{Z}/2\mathbb{Z})^2\]

by Corollary 3.4. We shall prove these 2-torsion points correspond to effective theta characteristics on \(F_7\).

Proof of Theorem 1.1 (for \(p = 7\)). We recall the results of Gross-Rohrlich on divisors on \(F_7\) representing elements of \(\text{Jac}(F_7)[2](\mathbb{Q}) \cong (\mathbb{Z}/2\mathbb{Z})^2\). (See [12, p. 209, (3)] for details.)

Let \(\varepsilon \in \overline{\mathbb{Q}}\) be a primitive 14-th root of unity, and we put \(\zeta := \varepsilon^2\). Let \(\eta \in \overline{\mathbb{Q}}\) be a primitive 6-th root of unity. Then \(\eta\) is conjugate to \(\eta^{-1}\) over \(\mathbb{Q}\). We put

\[P := (\eta, \eta^{-1}, -1), \quad Q := (\eta^{-1}, \eta, -1), \quad R_j := (\varepsilon\zeta^j, 1, 0) \quad (0 \leq j \leq 6)\]

Define a divisor \(D\) of degree 0 on \(F_7\) by

\[D := \sum_{j=0}^{6} \left( (A^3B)^j(P) + (A^3B)^j(Q) - 2R_j \right),\]

where \(A, B\) are the automorphisms of \(F_7\) defined in the proof of Lemma 3.3. The divisor \(D\) is invariant under the action of \(\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})\). Hence the line bundle \(\mathcal{O}_{F_7}(D)\) is defined over \(\mathbb{Q}\).

It is straightforward to confirm that the divisor of the rational function

\[f := X_2^{-4}(X_1^3X_2 + X_0X_2^3 - X_0^3X_1)\]

on \(F_7\) is equal to \(2D\). Hence \(2D\) is a principal divisor, and \(D\) gives a \(\mathbb{Q}\)-rational 2-torsion point

\[[D] \in \text{Jac}(F_7)[2](\mathbb{Q})\]

Gross-Rohrlich proved that the divisor class \([D]\) is non-trivial, and

\[\text{Jac}(F_7)[2](\mathbb{Q}) = \{0, [D], [\sigma(D)], [\sigma^2(D)]\}\]

Here \(\sigma: F_7 \rightarrow F_7\) is the automorphism of order 3 defined by

\[\sigma(X_0, X_1, X_2) := (X_1, X_2, X_0)\]

Recall that \(\mathcal{O}_{F_7}(2) := \mathcal{O}_{F_7}(2)|_{F_7}\) is an effective theta characteristic on \(F_7\). (See the proof of Corollary 2.5) Since \(F_7\) has a \(\mathbb{Q}\)-rational point such as \((1, -1, 0)\), there are exactly 4 isomorphism classes of theta characteristics on \(F_7\) by Corollary 2.3 (2). They are represented by the following line bundles

\[\mathcal{O}_{F_7}(2), \quad \mathcal{O}_{F_7}(2) \otimes \mathcal{O}_{F_7}(D), \quad \mathcal{O}_{F_7}(2) \otimes \mathcal{O}_{F_7}(\sigma(D)), \quad \mathcal{O}_{F_7}(2) \otimes \mathcal{O}_{F_7}(\sigma^2(D))\]

By Proposition 2.2 we need to prove that all of these theta characteristics are effective. We have already seen that \(\mathcal{O}_{F_7}(2)\) is effective. Since the automorphism \(\sigma\) permutes the three theta characteristics on \(F_7\) except \(\mathcal{O}_{F_7}(2)\), it is enough to show that one of them is effective.
We shall show $\mathcal{O}_{F_7}(2) \otimes \mathcal{O}_{F_7}(D)$ is effective. The line bundle $\mathcal{O}_{F_7}(2) \otimes \mathcal{O}_{F_7}(D)$ is effective if and only if the divisor $D + 2H$ is linearly equivalent to an effective divisor, where $H$ is a hyperplane section (i.e. $H$ is a divisor on $F_7$ cut out by a line in $\mathbb{P}^2_\mathbb{Q}$). Consider the line at infinity $\ell_\infty \subset \mathbb{P}^2_\mathbb{Q}$ defined by $X_2 = 0$. The line $\ell_\infty$ intersects with $F_7$ at the 7 points $R_0, R_1, \ldots, R_6$. All of the intersection points have multiplicity one. (Since $F_7 \subset \mathbb{P}^2_\mathbb{Q}$ is a plane curve of degree 7, there are exactly 7 intersections counted with their multiplicities by Bézout’s theorem ([13, I., 7.8], [19, Corollary 9.1.20]).) The divisor $\ell_\infty \cap F_7$ on $F_7$ cut out by $\ell_\infty$ is equal to $\sum_{j=0}^{6} R_j$. Since $D$ is a divisor on $F_7$ isomorphic to the projective smooth model $\mathbb{C}$ is a bitangent to $\mathbb{C}$ effective if and only if the divisor $D$ is effective by Bézout’s theorem. Hence we have $\mathcal{O}_{F_7}(2) \otimes \mathcal{O}_{F_7}(D)$ is effective, we conclude that $\mathcal{O}_{F_7}(2) \otimes \mathcal{O}_{F_7}(D)$ is an effective theta characteristic on $F_7$.

The proof of Theorem 1.1 for $p = 7$ is complete. □

5. Symmetric determinantal representations of the Klein quartic over $\mathbb{Q}$

The Klein quartic is a smooth plane curve of degree 4 over $\mathbb{Q}$ defined by the equation

$$C_{Kl} := (X_4^3X_1 + X_1^3X_2 + X_2^3X_0 = 0) \subset \mathbb{P}^2_\mathbb{Q}.$$ 

In this section, we study symmetric determinantal representations of $C_{Kl}$ over $\mathbb{Q}$. For an excellent exposition of the arithmetic and the geometry of the Klein quartic, see [10].

The following arithmetic results on the Klein quartic must be well-known.

Lemma 5.1. (1) $\text{Jac}(C_{Kl})[2](\mathbb{Q}) \cong \mathbb{Z}/2\mathbb{Z}$.

(2) There is an effective theta characteristic on $C_{Kl}$ defined over $\mathbb{Q}$.

Proof. (1) It seems possible to work with the defining equation of $C_{Kl}$ directly. Here we shall deduce it from the results of Gross-Rohrlich ([12]). The Klein quartic $C_{Kl}$ is isomorphic to the projective smooth model $C_2$ of the affine curve $V^7 = U(1-U)^2$ ([10, p. 67]). This can be seen as follows. We have a rational map

$$C_{Kl} \dashrightarrow C_2, \quad (a, b, c) \mapsto (s, t) := (-a^2b/c^3, -b/c)$$

Since $t^7 = s(1-s)^2$ is satisfied, $(s, t)$ lies on the affine curve $V^7 = U(1-U)^2$. Conversely, since $c/b = -1/t$, $a/b = t^2/(s-1)$, the homogeneous coordinates of $(a, b, c)$ are recovered from $(s, t)$ when $s \neq 1$, $t \neq 0$. Hence $C_{Kl}$ is birational to $C_2$ over $\mathbb{Q}$. Since $C_{Kl}$, $C_2$ are projective smooth curves over $\mathbb{Q}$, they are isomorphic over $\mathbb{Q}$ ([13, I., 6.12], [19, Proposition 7.3.13 (b)]). Hence we have $C_{Kl} \cong C_2$, and

$$\text{Jac}(C_{Kl})[2](\mathbb{Q}) \cong \text{Jac}(C_2)[2](\mathbb{Q}) \cong \mathbb{Z}/2\mathbb{Z}$$

by Theorem 5.1.

(2) Let $\zeta_3 \in \overline{\mathbb{Q}}$ be a primitive cube root of unity. Consider $\overline{\mathbb{Q}}$-rational points $P := (\zeta_3, \zeta_3^2, 1)$ and $Q := (\zeta_3^2, \zeta_3, 1)$ on $C_{Kl}$. The line $X_0 + X_1 + X_2 = 0$ is a bitangent to $C_{Kl}$ at $P, Q$. Since $P + Q$ is a $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-invariant divisor on $C_{Kl} \otimes \overline{\mathbb{Q}}$, the line bundle $\mathcal{O}_{C_{Kl}}(P + Q)$ is defined over $\mathbb{Q}$. The canonical sheaf $\Omega_{C_{Kl}}$ is isomorphic
to the restriction $\mathcal{O}_{\mathcal{C}_K}(1) := \mathcal{O}_{\mathbb{P}^2}(1)|_{\mathcal{C}_K}$. Since the divisor $2P + 2Q$ on $\mathcal{C}_K$ is cut out by a line, we have $\mathcal{O}_{\mathcal{C}_K}(2P + 2Q) \cong \mathcal{O}_{\mathcal{C}_K}(1)$. Hence $\mathcal{O}_{\mathcal{C}_K}(P + Q)$ is an effective theta characteristic on $\mathcal{C}_K$ defined over $\mathbb{Q}$.

Remark 5.2. There are 28 bitangents to a smooth plane quartic defined over an algebraically closed field of characteristic different from two. There is a bijection between bitangents and isomorphism classes of effective theta characteristics ([7, Ch. 6]). The defining equations of the 28 bitangents to the Klein quartic $\mathcal{C}_K \otimes \mathbb{Q}$ over $\mathbb{Q}$ can be found in [22, Proposition 9]. In fact, Shioda calculated the defining equations over any algebraically closed fields of characteristic different from 7. One can verify that $X_0 + X_1 + X_2 = 0$ is a unique bitangent defined over $\mathbb{Q}$.

Proof of Theorem 1.4. Since $\mathcal{C}_K$ has a $\mathbb{Q}$-rational point such as $(1, 0, 0)$, there are exactly two theta characteristics on $\mathcal{C}_K$, up to isomorphism, by Corollary 2.3 (2) and Lemma 5.1. Since $\mathcal{C}_K$ admits a symmetric determinantal representation over $\mathbb{Q}$ (cf. the equation (1.1) in Introduction), there is a non-effective theta characteristic on $\mathcal{C}_K$ by Proposition 2.2. On the other hand, there is an effective theta characteristic on $\mathcal{C}_K$ by Lemma 5.1 (2). Therefore, there is a unique isomorphism class of non-effective theta characteristics on $\mathcal{C}_K$ over $\mathbb{Q}$. The assertion follows from Proposition 2.2.
