COHERENT IC-SHEAVES ON TYPE $A_n$ AFFINE GRASSMANNIANS AND DUAL CANONICAL BASIS OF AFFINE TYPE $A_1$

MICHAEL FINKELBERG AND RYO FUJITA

Abstract. The convolution ring $K^{GL_n(\mathcal{O})\times \mathbb{C}^\times}(Gr_{GL_n})$ was identified with a quantum unipotent cell of the loop group $LSL_2$ in [CW19]. We identify the basis formed by the classes of irreducible equivariant perverse coherent sheaves with the dual canonical basis of the quantum unipotent cell.

1. Introduction

1.1. The affine Grassmannian $Gr_{GL_n} = GL_n(K)/GL_n(\mathcal{O})$ (where $K = \mathbb{C}(t)$, $\mathcal{O} = \mathbb{C}[[t]]$), is a basic object of the geometric Langlands program. The convolution ring $K^{GL_n(\mathcal{O})\times \mathbb{C}^\times}(Gr_{GL_n})$ (where $\mathbb{C}^\times$ acts by loop rotations) is a simplest example of the quantized $K$-theoretic Coulomb branch of a quiver gauge theory (for $A_1$-quiver). The corresponding non-quantized $K$-theoretic Coulomb branch $K^{GL_n(\mathcal{O})}(Gr_{GL_n})$ is a commutative ring, whose spectrum is the trigonometric zastava space $\mathcal{Z}_{sl_2}^n$ of type $A_1$ and degree $n$ (alias moduli space of periodic $SU(2)$-monopoles of topological charge $n$). This space was thoroughly studied in yet another disguise in [GSV11], where its coordinate ring was equipped with a cluster structure.

It is expected by physicists that all the $K$-theoretic Coulomb branches of gauge theories should carry a (generalized) cluster structure (for trigonometric zastava see [FKR18]). Moreover, it is expected that the quantized $K$-theoretic Coulomb branches should carry a quantum cluster structure. In the simplest example of $K^{GL_n(\mathcal{O})\times \mathbb{C}^\times}(Gr_{GL_n})$ such a structure was exhibited in [CW19]. It was identified with a well known cluster structure on a quantum unipotent cell of the loop group $LSL_2$ (in the non-quantized case, general trigonometric zastava spaces are identified with appropriate affine Richardson varieties in [FKR18]).

Furthermore, all the cluster monomials of this cluster structure have a nice geometric meaning as classes in $K^{GL_n(\mathcal{O})\times \mathbb{C}^\times}(Gr_{GL_n})$ of certain irreducible $GL_n(\mathcal{O})\times \mathbb{C}^\times$-equivariant perverse coherent sheaves on the affine Grassmannian $Gr_{GL_n}$. The abelian monoidal category $F_{coh}^{GL_n(\mathcal{O})\times \mathbb{C}^\times}(Gr_{GL_n})$ of perverse coherent sheaves was introduced in [BFM05]. Its $K$-ring coincides with $K^{GL_n(\mathcal{O})\times \mathbb{C}^\times}(Gr_{GL_n})$, and it is equipped with a distinguished basis formed by the classes of IC-sheaves: irreducible equivariant perverse coherent sheaves. The problem of algebraic computation of this distinguished basis was standing ever since the appearance of [BFM05], and the cluster monomials description of certain IC-classes given in [CW19] was a breakthrough in this direction. However, the IC-classes representable as cluster monomials only form a tip of the iceberg of all the IC-classes; namely, they are

2010 Mathematics Subject Classification. Primary: 17B37, 22E67, Secondary: 13F60.
IC-extensions of certain equivariant line bundles on $GL_n(O)$-orbits in $\text{Gr}_{GL_n}$ (so this is similar to the lowest KL-cell in an affine Hecke algebra).

Now the cluster monomials in a quantum unipotent cell of $\text{LSL}_2$ form a part of the dual canonical basis of the quantum group $U_q^{\pm} (\mathfrak{sl}_2)$ (more precisely, of a certain localization of a subalgebra of its restricted dual) thanks to [KKKO18]. So it is natural to expect that this dual canonical basis corresponds to the above distinguished basis formed by the IC-classes. This is indeed proved in the present paper.

The dual canonical basis is characterized by two properties: (1) invariance with respect to a certain bar-involution; (2) the fact that the transformation matrix to the dual canonical basis from the dual PBW basis is identity modulo $q^{-1}$ (where $\mathbb{Z}[q^{\pm 1}] = K_{\mathbb{C}^*}(\text{pt})$). The corresponding bar-involution on $K^{GL_n(O) \times \mathbb{C}^*}(\text{Gr}_{GL_n})$ (fixing IC-classes) was introduced in [CW19]. The dual PBW basis corresponds to certain convolutions of line bundles on the first minuscule orbit in $\text{Gr}_{GL_n}$. The analogue of property (2) for the usual constructible IC-sheaves is very deep (it boils down to the Riemann-Weil conjecture proved by Deligne). In the coherent setting of equivariant sheaves on nilpotent cone $P_{coh}^{GL_d \times \mathbb{C}^*}(\mathcal{N}_{PGL_d})$ a similar property was proved by Bezrukavnikov in [B06] by making use of his coherent-constructible correspondence and reducing to the above result of Deligne. In this setting the role of dual PBW basis is played by the classes of Andersen-Jantzen sheaves (pushforwards of the dominant line bundles from the Springer resolution of the nilpotent cone).

We are able to check the property (2) by reducing it to Bezrukavnikov’s theory for $P_{coh}^{GL_d \times \mathbb{C}^*}(\mathcal{N}_{PGL_d})$. Namely, we consider a closed subvariety $\text{Gr}_d^n \subset \text{Gr}_{GL_n}$ formed by all the sublattices of codimension $d$ in the standard lattice $O^n \subset K^n$. Then we have a natural smooth morphism of stacks

$$\psi: [(GL_n(O) \times \mathbb{C}^*)/\text{Gr}_d^n] \to [(GL_d \times \mathbb{C}^*)/\mathcal{N}_{PGL_d}],$$

and $\psi^*$ takes coherent IC-sheaves to IC-sheaves, and the Andersen-Jantzen sheaves to the appropriate $d$-fold convolutions of line bundles on $\text{Gr}_d^n$.

The appearance of the dual canonical basis is natural from yet another point of view. According to [FT19], $K^{GL_n(O) \times \mathbb{C}^*}(\text{Gr}_{GL_n})$ is the homomorphic image of a certain integral form (i.e. a $\mathbb{Q}[q^{\pm 1}]$-subalgebra) of a shifted quantum affine algebra of type $\mathbb{A}_1$. This integral form is spanned by the dual Poincaré-Birkhoff-Witt-Drinfeld basis.

Finally, we should note that the problem of algebraic characterization of the IC-basis of $K^{G(O) \times \mathbb{C}^*}(\text{Gr}_G)$ makes sense for arbitrary reductive group $G$, and we have no clue how to approach it for $G \neq GL_n$.

1.2. Acknowledgments. We are grateful to R. Bezrukavnikov, S. Cautis, S. Kato, A. Tsymbaliuk and H. Williams for the useful discussions. Moreover, the key idea to apply the relation between affine Grassmannians of type $A$ and nilpotent cones of type $A$ (going back to [L81]) to computation of classes of coherent IC-sheaves is due to R. Bezrukavnikov.

M.F. was partially funded within the framework of the HSE University Basic Research Program and the Russian Academic Excellence Project ‘5-100’. R.F. was supported by Grant-in-Aid for JSPS Research Fellow (No. 18J10669) and in part by Kyoto Top Global University program.
1.3. Overall convention. A variety always means a complex algebraic variety. Let $X$ be a variety equipped with an action of a complex algebraic group $G$. For a (closed) point $x \in X$, we denote by $\text{Stab}_G x$ the stabilizer of $x$ in $G$. We denote by $D^G_{coh}(X)$ (resp. $D^G_{qcoh}(X)$) the derived category of bounded (resp. unbounded) $G$-equivariant complexes of sheaves on $X$ whose cohomologies are coherent (resp. quasi-coherent). We denote by $D^G_{\text{SR}}$ the Grothendieck-Serre duality functor on $D^G_{coh}(X)$, where $\omega_X$ is a $G$-equivariant dualizing complex on $X$. For a group automorphism $\rho$ of $G$, we denote by $X^\rho$ the same variety $X$ with a new $G$-action obtained by twisting the original $G$-action by $\rho$. For an object $\mathcal{F} \in D^G_{coh}(X)$, we denote by $\mathcal{F}^\rho$ the sheaf obtained by twisting the $G$-equivariant structure of $\mathcal{F}$ by $\rho$. Then $\mathcal{F}^\rho$ is an object of $D^G_{coh}(X^\rho)$.

For an abelian category $\mathcal{A}$, we denote by $\text{Irr}\mathcal{A}$ the set of isomorphism classes of simple objects of $\mathcal{A}$. We abbreviate $\text{Irr} G := \text{Irr} \text{Rep}(G)$, where $\text{Rep}(G)$ is the category of finite-dimensional algebraic representations of $G$ over $\mathbb{C}$.

2. Quantum unipotent cell of $\text{LSL}_2$

2.1. Quantum algebras of type $A^{(1)}_1$. Let $\begin{pmatrix} a_{00} & a_{01} \\ a_{10} & a_{11} \end{pmatrix} = \begin{pmatrix} 2 & -2 \\ -2 & 2 \end{pmatrix}$ be the generalized Cartan matrix of type $A^{(1)}_1$ and $Q := \mathbb{Z}a_0 \oplus \mathbb{Z}a_1$ be the root lattice ($a_0, a_1$ are the simple roots). We define a symmetric bilinear form $(\cdot, \cdot)$ on $Q$ by $(\alpha_i, \alpha_j) = a_{ij}$ for $i, j \in \{0, 1\}$. We set $Q^+ := \mathbb{N}a_0 + \mathbb{N}a_1 \subset Q$.

Let $U^+ \equiv q^+_2(\mathfrak{sl}_2)$ be the $Q(q)$-algebra generated by the two generators $\{e_0, e_1\}$ satisfying the quantum Serre relation

$$e_i^2 e_j - (q^2 + q^{-2}) e_i e_j e_i + (q^2 + q^{-2}) e_i e_j e_i^2 - e_i e_j^3 = 0$$

for $\{i, j\} = \{0, 1\}$. The algebra $U^+$ is the positive (or the upper triangular) part of the quantized enveloping algebra $U_q(\mathfrak{sl}_2)$. We define the weight grading $U^+ = \bigoplus_{\beta \in Q} U^+_\beta$ by setting $\text{deg} e_i := a_i$.

We equip the tensor square $U^+ \otimes_{Q(q)} U^+$ with a $Q(q)$-algebra structure by

$$(x_1 \otimes x_2, (y_1 \otimes y_2)) := q^{(\beta_2, \gamma_1)} x_1 y_1 \otimes x_2 y_2,$$

where $x_i \in U^+_\beta$, $y_i \in U^+_{-\beta}$. Let $r : U^+ \to U^+ \otimes_{Q(q)} U^+$ be a $Q(q)$-algebra homomorphism given by

$$r(e_i) := e_i \otimes 1 + 1 \otimes e_i$$

for $i = 0, 1$. Let $A = \bigoplus_{\beta \in Q^+} A_{\beta} = \bigoplus_{\beta \in Q} \text{Hom}_{Q(q)}(U^+_{\beta}, Q(q))$ be the restricted dual of $U^+$ with a $Q(q)$-algebra structure given by the dual of $r$.

Following Lusztig [L93, Proposition 1.2.3], we define a nondegenerate symmetric $Q(q)$-bilinear form $(\cdot, \cdot)_L$ on $U^+$ by

$$(1, 1)_L = 1, \ (e_i, e_j)_L = (1 - q^2)^{-1} \delta_{ij}, \ (x, yz)_L = (r(x), y \otimes z)_L,$$

where $(x \otimes y, z \otimes w)_L := (x, z)_L \cdot (y, w)_L$. The bilinear form $(\cdot, \cdot)_L$ induces a $Q(q)$-algebra isomorphism $\psi_L : U^+ \cong A$ defined by $\langle \psi_L(x), y \rangle = (x, y)_L$, where $\langle \cdot, \cdot \rangle : A \times U^+ \to Q(q)$ is the natural pairing.

We define an algebra involution $b$ of $U^+$ by

$$b(q) = q^{-1}, \ b(e_i) = e_i.$$
Let \( b^* \) denote the \( \mathbb{Q} \)-linear involution of \( A \) defined as the dual of \( b \), i.e. for \( \theta \in A, x \in U^+ \), we define
\[
\langle b^*(\theta), x \rangle := \overline{\theta(b(x))}
\]
where \( \overline{f(q)} := f(q^{-1}) \) for \( f(q) \in \mathbb{Q}(q) \). Then for \( \theta_i \in A_{\beta_i} (i = 1, 2) \), we have
\[
b^*(\theta_1 \theta_2) = q^{-(\beta_1, \beta_2)} b^*(\theta_2) b^*(\theta_1).
\]

2.2. Quantum unipotent subgroup. We fix \( n \in \mathbb{N} \) throughout this paper. Let \( w_n = s_{i_1} \cdots s_{i_{2n}} := (s_0 s_1)^n \) be an element of the Weyl group of type \( A_1^{(1)} \) of length \( 2n \), where \( s_i \) is the simple reflection associated with the index \( i \in \{0, 1\} \). For each \( 1 \leq k \leq 2n \), we define the positive root \( \beta_k \) by
\[
\beta_k := s_{i_1} \cdots s_{i_{k-1}} (\alpha_{i_k}) = k\alpha_0 + (k - 1)\alpha_1.
\]
The roots \( \beta_1, \ldots, \beta_{2n} \) are all the positive roots \( \alpha \) such that \( w_n^{-1}(\alpha) < 0 \). Define the corresponding root vectors by
\[
E(\beta_k) := T_{i_1} \circ \cdots \circ T_{i_{k-1}}(e_{i_k})
\]
for \( 1 \leq k \leq 2n \), where \( T_i \) denotes Lusztig’s symmetry (= \( T'_{i-1} \) in Lusztig’s notation, see [L93, 37.1] for the definition). Let \( U_n^+ \subset U^+ \) be the \( \mathbb{Q}(q) \)-subalgebra generated by \( \{ E(\beta_k) \mid 1 \leq k \leq 2n \} \). The subalgebra \( A_n := \psi_L(U_n^+) \) of \( A \) is called the quantum unipotent subgroup associated with \( w_n \). Both algebras \( U_n^+ \) and \( A_n \) inherit the \( \mathbb{Q}^+ \)-gradings from \( U^+ \) and \( A \):
\[
U_n^+ = \bigoplus_{\beta \in \mathbb{Q}^+} (U_n^+)_{\beta}, \quad A_n = \bigoplus_{\beta \in \mathbb{Q}^+} (A_n)_{\beta}.
\]

2.3. PBW and dual PBW bases. For an element \( \beta \in \mathbb{Q}^+ \), we set
\[
KP_n(\beta) := \{ a = (a_1, \ldots, a_{2n}) \in (\mathbb{Z}_{\geq 0})^{2n} \mid a_1\beta_1 + \cdots + a_{2n}\beta_{2n} = \beta \}.
\]
For each \( a = (a_1, a_2, \ldots, a_{2n}) \in KP_n(\beta) \), we define the corresponding PBW element as the product of \( q \)-divided powers by
\[
E(a) := E(\beta_1)^{a_1} E(\beta_2)^{a_2} \cdots E(\beta_{2n})^{a_{2n}},
\]
where \( x^{(q)} := x^q / (\prod_{i=1}^q [i]) \), \([i] := q^i - q^{-i}\) as usual. Then the set \( \{ E(a) \mid a \in KP_n(\beta) \} \) forms a \( \mathbb{Q}(q) \)-basis of \( (U_n^+)_{\beta} \). It is known (cf. [L93, Proposition 38.2]) that we have \( (E(a), E(b))_L = 0 \) if \( a \neq b \) and
\[
(E(a), E(a))_L = \prod_{k=1}^{2n} a_k \prod_{j=1}^n (1 - q^{-2j})^{-1}.
\]
For each \( a \in KP_n(\beta) \), we define the dual PBW element in \( A_n \) by
\[
E^*(a) := \psi_L(E(a)) / (E(a), E(a))_L.
\]
By construction, the set \( \{ E^*(a) \mid a \in KP_n(\beta) \} \) forms a \( \mathbb{Q}(q) \)-basis of \( (A_n)_\beta \) dual to the basis \( \{ E(a) \mid a \in KP_n(\beta) \} \) of \( (U_n^+)_{\beta} \).

The dual PBW element \( E^*(a) \) can be written simply as a product of the dual root vectors \( E^*(\beta_k) = (1 - q^{-2}) \psi_L(E(\beta_k)) \):
\[
(2.1) \quad E^*(a) = q^{-\sum_{k=1}^2 a_k(a_k-1)/2} E^*(\beta_1)^{a_1} E^*(\beta_2)^{a_2} \cdots E^*(\beta_{2n})^{a_{2n}}.
\]
2.4. Dual canonical basis. Let $\mathcal{B} \subset U^+$ be the canonical basis of $U^+$ constructed in [L93, Part II]. It is characterized up to sign as the set of elements $b \in U^+$ satisfying $b(b) = b$ and $(b, b)_L \in 1 + q^{-1} \mathbb{Z}[q^{-1}]$. The dual canonical basis $\mathcal{B}^*$ is defined as the basis of $A$ dual to the canonical basis $\mathcal{B}$. By definition, each element of $\mathcal{B}^*$ is fixed by the bar involution $b^*$. Moreover we have $\mathcal{B}^* = (\mathcal{B})^* = (\mathcal{B}^*)^*$.

The following theorem due to Kimura [K12] claims that the dual canonical basis is compatible with the quantum unipotent subgroup $A_n$ and characterized by using the dual PBW basis.

**Theorem 2.1** ([K12, Theorem 4.29]). For each $\beta \in \mathbb{Q}^+$, there exists a unique $\mathbb{Q}(q)$-basis $\mathcal{B}_n(\beta) = \{B^*(a) \mid a \in \mathcal{K}(\pi_n(\beta))\}$ of $(\mathcal{A}_n)_\beta$ characterized by the following properties:

1. $b^*(B^*(a)) = B^*(a)$;
2. $B^*(a) \in E^*(a) + \sum_{a' \in \mathcal{K}(\pi_n(\beta))} q^{-1} \mathbb{Z}[q^{-1}] E^*(a')$.

Moreover we have $\mathcal{B}_n(\beta) = \mathcal{B}^* \cap (\mathcal{A}_n)_\beta$.

We refer to the basis $\bigcup_{\beta \in \mathbb{Q}^+} \mathcal{B}_n(\beta)$ as the dual canonical basis of $A_n$. We denote by $A_{n,\mathbb{Z}}$ the integral form of $A_n$, i.e., the $\mathbb{Z}(q^{1/2})$-subalgebra of $A_n$ spanned by the dual canonical basis (or the dual PBW basis).

Let $\mathcal{U} = \mathbb{Z}[w_0, \mathbb{Z}w_1$ be the weight lattice of type $A_1^{(1)}$ with $w_i$ being the $i$-th fundamental weight ($i \in \{0, 1\}$). For a dominant weight $\lambda \in \mathcal{P}^+ : = \mathbb{N}w_0 + \mathbb{N}w_1$ and Weyl group elements $u$ and $v$ satisfying $u(\lambda) - v(\lambda) \in \mathbb{Q}^+$, we denote by $D_{u,\pi, v}(\lambda)$ the corresponding quantum unipotent minor (see [GLS13, Section 5.2] for the definition). This is an element of $\mathcal{B}_n(u(\lambda) - v(\lambda))$ (see [GLS13, Proposition 6.3]). For each $1 \leq k \leq 2n$, we set $w_{\leq k} := s_{i_1}s_{i_2}\cdots s_{i_k}$ and $w_{<k} := s_{i_1}s_{i_2}\cdots s_{i_{k-1}}$. For each $1 \leq b \leq d \leq 2n$ with $d - b \in 2\mathbb{Z}$, we define $D_{b, d} := D_{w_{\leq b}w_{\leq d}, w_{<b}w_{<d}}$. By [GLS13, Proposition 7.4], we have $E^*(\beta_k) = D[k, k]$ for each $1 \leq k \leq 2n$.

2.5. Quantum cluster structure. Let $\mathcal{A}_n$ be the quantum cluster algebra (over $\mathbb{Z}(q^{1/2})$) associated with the initial quantum seed $\mathcal{S} = (\{X_1, \ldots, X_{2n}\}, \tilde{B}, \Lambda)$ defined as follows (see [BZ05] for the generalities of quantum cluster algebras). The exchange matrix $\tilde{B}$ is the $2n \times (2n - 2)$-matrix given by

$$
\tilde{B} := \begin{pmatrix}
0 & -2 & 1 \\
2 & 0 & -2 & 1 \\
-1 & 2 & 0 & -2 & 1 \\
& & \ddots & \ddots & \ddots \\
& & -1 & 2 & 0 & -2 & 1 \\
& & & -1 & 2 & 0 & -2 \\
& & & & -1 & 2 & 0 \\
& & & & & -1 & 2 \\
& & & & & & -1 \\
\end{pmatrix},
$$

where all blank entries are 0. The skew-symmetric $2n \times 2n$-matrix $\Lambda = (\Lambda_{k, \ell})$ is given by $\Lambda_{k, \ell} := 2[k/2](|k/2| - |\ell/2|)$ for any $1 \leq k < \ell \leq 2n$ (cf. [CW19, Lemma 6.4]). The quantum cluster algebra $\mathcal{A}_n$ is a $\mathbb{Z}(q^{1/2})$-subalgebra of the based quantum torus $\mathbb{Z}(q^{1/2})[X_k^{\pm 1} (1 \leq k \leq 2n) \mid X_kX_\ell = q^{\Lambda_{k, \ell}}X_\ell X_k]$. 
For each $1 \leq b \leq d \leq 2n$ with $d - b \in 2\mathbb{Z}$, we consider the following normalized element in $\mathbb{Q}(q^{1/2}) \otimes_{\mathbb{Q}(q)} A_n$:

$$\tilde{D}[b, d] := q^{(\beta, \beta)/4}D[b, d],$$

where $\beta = w_{<b}w_{b} - w_{\leq d}w_{d}$ is the weight of $D[b, d]$. More generally, for any quantum unipotent minor $D_{u(\lambda), v(\lambda)}$, we define $\tilde{D}_{u(\lambda), v(\lambda)} := q^{(\beta, \beta)/4}D_{u(\lambda), v(\lambda)}$ with $\beta = u(\lambda) - v(\lambda) \in \mathbb{Q}^+$.

**Theorem 2.2** ([GLS13, Theorem 12.3], [KKKO18, Corollary 11.2.8]). There is a unique isomorphism

$$\mathcal{A}_n \xrightarrow{\sim} \mathbb{Z}[q^{\pm 1/2}] \otimes_{\mathbb{Z}[q^\pm 1]} A_{n, \mathbb{Z}}$$

under which the initial cluster variable $X_k$ corresponds to

$$\begin{cases} \tilde{D}[1, k] & \text{if } k \text{ is odd;} \\ \tilde{D}[2, k] & \text{if } k \text{ is even,} \end{cases}$$

for each $1 \leq k \leq 2n$. Moreover the quantum unipotent minor $\tilde{D}[b, d]$ is the image of a cluster variable for any $1 \leq b \leq d \leq 2n$ with $d - b \in 2\mathbb{Z}$.

Henceforth, we will identify the quantum unipotent subgroup $\mathbb{Z}[q^{\pm 1/2}] \otimes_{\mathbb{Z}[q^\pm 1]} A_{n, \mathbb{Z}}$ with the quantum cluster algebra $\mathcal{A}_n$ via the isomorphism in Theorem 2.2.

### 2.6. Berenstein-Zelevinsky’s bar involution

When $x, y$ are $q$-commuting with each other, say $xy = q^m yx$ for some $m \in \mathbb{Z}$, we write $x \odot y := q^{-m/2}xy$. Note that we have $x \odot y = y \odot x$. Following Berenstein-Zelevinsky [BZ05a], let us consider the algebra anti-involution $\iota$ of the quantum cluster algebra $\mathcal{A}_n$ defined by

$$\iota(q) = q^{-1}, \quad \iota(X_k) = X_k,$$

for all $1 \leq k \leq 2n$. If $x, y \in \mathcal{A}_n$ are $q$-commuting with each other and both are fixed by $\iota$, the element $x \odot y = y \odot x$ is also fixed by $\iota$. In particular, any cluster variables and hence any cluster monomials are fixed by $\iota$.

**Lemma 2.3** (cf. [KO19, Remark 7.23]). If $x \in \mathcal{A}_n$ is of weight $\beta$, we have $\iota(x) = q^{(\beta, \beta)/2}b^*(x)$. In particular, $x$ is fixed by $b^*$ if and only if the rescaled element $q^{(\beta, \beta)/4}x$ is fixed by $\iota$.

For any $\beta \in \mathbb{Q}^+$ and $a \in \text{KP}_n(\beta)$, we consider the rescaled elements

$$\tilde{B}(a) := q^{(\beta, \beta)/4}B^*(a), \quad \tilde{E}(a) := q^{(\beta, \beta)/4}E^*(a).$$

Theorem 2.1 yields the following characterization of the rescaled dual canonical basis.

**Corollary 2.4.** The basis $\{\tilde{B}(a) \mid a \in \text{KP}_n(\beta)\}$ of $(\mathcal{A}_n)_\beta$ is characterized by the following properties:

1. $\iota(\tilde{B}(a)) = \tilde{B}(a)$;
2. $\tilde{B}(a) \in \tilde{E}(a) + \sum_{a' \in \text{KP}_n(\beta)} q^{-1}Z[q^{-1}]\tilde{E}(a')$.

Note that in particular the rescaled dual root vector is

$$\tilde{E}(\beta_k) = q^{1/2}E^*(\beta_k) = \tilde{D}[k, k]$$

for each $1 \leq k \leq 2n$. In terms of the rescaled elements, the expression (2.1) is rewritten as

$$\tilde{E}(a) = q^{\sum_{1 \leq i \leq n} a_ka_i} \tilde{E}(\beta_1)^{a_1} \tilde{E}(\beta_2)^{a_2} \cdots \tilde{E}(\beta_{2n})^{a_{2n}}$$
for each \( a \in KP_n(\beta) \).

2.7. Localization. Note that the frozen variables of the quantum cluster algebra \( \mathcal{A}_n \) are the following two elements:

\[
D_0 := X_{2n-1} = \bar{D}_{w_0}, \quad D_1 := X_{2n} = \bar{D}_{w_1}.
\]

**Proposition 2.5** (cf. [KO19, Proposition 4.2]). For each \( \lambda \in P^+ \), the unipotent quantum minor \( D_{\lambda,w,\lambda} \) is \( q \)-central in \( A_n \). More precisely, for any homogeneous element \( x \in (\mathcal{A}_n)_\beta \) of weight \( \beta \in \mathbb{Q}^+ \), we have \( D_{\lambda,w,\lambda} x = q^{-(\lambda + w_0, \lambda)} x D_{\lambda,w,\lambda} \).

Moreover, for \( \lambda, \lambda' \in P^+ \), we have \( D_{\lambda,w,\lambda} \circ D_{\lambda,w,\lambda'} = D_{\lambda + \lambda', w_0(\lambda' + \lambda)} \) in \( \mathcal{A}_n \). In particular, we have \( D_{\lambda,w,\lambda} = D_0^{\circ\ell_0} \circ D_1^{\circ\ell_1} \) for \( \lambda = \ell_0 w_0 + \ell_1 w_1 \in P^+ \).

By Proposition 2.5, the set \( \mathcal{D}_n := \{ q^m D_0^{\ell_0} D_1^{\ell_1} \mid m \in \mathbb{Z}, \ell_i \in \mathbb{N} \} \) is an Ore set of the algebra \( \mathcal{A}_n \). The localized algebra \( \mathcal{A}_n^{\text{loc}} := \mathcal{A}_n[\mathcal{D}_n^{-1}] \) is (isomorphic to) the quantum unipotent cell associated with \( w_0 \) (cf. [KO19, Section 4]).

**Proposition 2.6** (cf. [KO19, Proposition 4.5]). The set

\[
\mathcal{B}_n^{\text{loc}} := \{ \bar{B}(a) \circ D_0^{\circ\ell_0} \circ D_1^{\circ\ell_1} \mid a \in \mathbb{N}^{2n}, \ell_i \in \mathbb{N} \}
\]

forms a \( \mathbb{Z}[q^{\pm 1/2}] \)-basis of the quantum unipotent cell \( \mathcal{A}_n^{\text{loc}} \).

Note that each element in \( \mathcal{B}_n^{\text{loc}} \) is fixed by the bar involution \( \iota \).

3. Perverse coherent sheaves on type A affine Grassmannian

3.1. Affine Grassmannian. Let \( T_n \subset GL_n(\mathbb{C}) \) be the maximal torus consisting of diagonal matrices and \( P^\vee := \text{Hom}(\mathbb{C}^\times, T_n) \) be the coweight lattice. We make the standard identification \( P^\vee = \mathbb{Z}^n \) under which the element \( \nu = (\nu_1, \ldots, \nu_n) \in \mathbb{Z}^n \) corresponds to the 1-parameter group \( a \mapsto \text{diag}(a^{\nu_1}, \ldots, a^{\nu_n}) \). The weight lattice \( P = \text{Hom}_\mathbb{C}(P^\vee, \mathbb{Z}) \) is also identified with \( \mathbb{Z}^n \) via the standard pairing \( \langle -,- \rangle : \mathbb{Z}^n \times \mathbb{Z}^n \rightarrow \mathbb{Z} \) given by \( \langle \nu, \mu \rangle = \nu_1 \mu_1 + \cdots + \nu_n \mu_n \). We say that an element \( \nu = (\nu_1, \ldots, \nu_n) \in \mathbb{Z}^n \) is dominant if \( \nu_1 \geq \cdots \geq \nu_n \). Write \( P^+_\nu \) for the set of dominant coweights. For each \( 1 \leq k \leq n \), we define

\[
\omega_k := (1, \ldots, 1, 0, \ldots, 0) \in \mathbb{Z}^n,
\]

which is regarded as the \( k \)-th fundamental weight or coweight.

Let \( K := \mathbb{C}((t)) \supset \mathcal{O} := \mathbb{C}[t] \) be the field of formal Laurent series and its subring of formal power series. We consider the affine Grassmannian of \( GL_n \):

\[
\text{Gr}_{GL_n} = GL_n(K)/GL_n(\mathcal{O}) = (GL_n(K) \rtimes \mathbb{C}^\times)/(GL_n(\mathcal{O}) \rtimes \mathbb{C}^\times),
\]

where \( \mathbb{C}^\times \) denotes the 4-fold cover of the standard loop rotation. More precisely, we have \( (1, a) \cdot (g(t), 1) = (g(a^{\nu} t), a) \) in \( GL_n(\mathcal{O}) \rtimes \mathbb{C}^\times \) for \( g(t) \in GL_n(\mathcal{O}), \; a \in \mathbb{C}^\times \).

The affine Grassmannian \( \text{Gr}_{GL_n} \) decomposes into the union of \( GL_n(\mathcal{O}) \)-orbits (= \( GL_n(\mathcal{O}) \rtimes \mathbb{C}^\times \)-orbits):

\[
\text{Gr}_{GL_n} = \bigsqcup_{\nu \in P^+_\nu} \text{Gr}^\nu_{GL_n},
\]

where \( \text{Gr}^\nu_{GL_n} \) denotes the orbit of \( [t^\nu] \in \text{Gr}_{GL_n} \), \( t^\nu := \text{diag}(t^{\nu_1}, \ldots, t^{\nu_n}) \in GL_n(K) \).

For each \( \nu = (\nu_1, \ldots, \nu_n) \in P^+_\nu \), we have \( \dim \text{Gr}^\nu_{GL_n} = \sum_{k=1}^n (n + 1 - 2k) \nu_k \).
The closure \( \overline{\text{Gr}}_{GL_n} \) of the orbit \( \text{Gr}_{GL_n}^\nu \) is called the Schubert variety. Let us consider the derived category \( D_{coh}^{GL_n(O) \times C^\times}(\overline{\text{Gr}}_{GL_n}^\nu) \) of bounded \( GL_n(O) \times C^\times \)-equivariant complexes of sheaves on the reduced scheme \( (\overline{\text{Gr}}_{GL_n}^\nu)_{red} \) with coherent cohomologies, formally supported in cohomological degrees \( \frac{1}{2} \dim \text{Gr}_{GL_n}^\nu + Z \) by convention.

The connected components of \( \text{Gr}_{GL_n} \) are labeled by \( Z \). For each \( d \in Z \), the \( d \)-th connected component \( \text{Gr}_{GL_n}^{(d)} \) is the union of \( GL_n(O) \)-orbits \( \text{Gr}_{GL_n}^\nu \) with \( d = \nu_1 + \cdots + \nu_n \). Note that the parity of \( \dim \text{Gr}_{GL_n}^\nu \) is constant on each connected component. Therefore we can define
\[
D_{coh}^{GL_n(O) \times C^\times}(\text{Gr}_{GL_n}^\nu) := \lim_{\nu \to \nu^\prime} D_{coh}^{GL_n(O) \times C^\times}(\overline{\text{Gr}}_{GL_n}^\nu).
\]

### 3.2. Convolution product.

For any objects \( F, G \in D_{coh}^{GL_n(O) \times C^\times}(\text{Gr}_{GL_n}^\nu) \), we can define their convolution product \( F \ast G \in D_{coh}^{GL_n(O) \times C^\times}(\text{Gr}_{GL_n}^\nu) \) by
\[
F \ast G := \overline{m}_! (F \boxtimes G),
\]
where \( \overline{m} : (GL_n(K) \times C^\times) \times (GL_n(O) \times C^\times) \text{Gr}_{GL_n} \to \text{Gr}_{GL_n} \) is the multiplication map. Here the sheaf \( F \boxtimes G \) is defined by the property \( \overline{p}^* (F \boxtimes G) \cong p^* (F \boxtimes G) \), where \( \overline{p} \) and \( p \) are the natural projections:
\[
\text{Gr}_{GL_n} \times \text{Gr}_{GL_n} \overset{\overline{p}}{\to} (GL_n(K) \times C^\times) \times \text{Gr}_{GL_n} \overset{\overline{q}}{\to} (GL_n(K) \times C^\times) \times GL_n(O) \times C^\times \text{Gr}_{GL_n}.
\]

If \( F \) (resp. \( G \)) is supported on \( \overline{\text{Gr}}_{GL_n}^\nu \) (resp. \( \overline{\text{Gr}}_{GL_n}^\nu \)), the sheaf \( F \boxtimes G \) is supported on the finite-dimensional convolution variety
\[
\overline{\text{Gr}}_{GL_n}^\nu \times \overline{\text{Gr}}_{GL_n}^\nu \subset GL_n(K) \times GL_n(O) \text{Gr}_{GL_n}
\]
and the convolution product \( F \ast G \) is supported on \( \overline{\text{Gr}}_{GL_n}^{\nu \ast \nu'} \).

The convolution product \( \ast \) equips the equivariant \( K \)-group \( K_{GL_n(O) \times C^\times}(\text{Gr}_{GL_n}^\nu) \) with a structure of an associative \( \mathbb{Z}[q^{1/2}] \)-algebra, where \( q^{m/2} \in K^{GL_n(O) \times C^\times}(pt) \) denotes the class of the pull-back of the 1-dimensional \( C^\times \)-module \( C_m \) of weight \( m \) along the natural projection \( GL_n(O) \times C^\times \to C^\times \).

We use the notation \( \{m/2\} \) to denote the \( C^\times \)-equivariant twist \( - \otimes C_{-m} \). Thus, for an object \( F \in D_{coh}^{GL_n(O) \times C^\times}(\text{Gr}_{GL_n}^\nu) \), we have \( \langle F \rangle = q^{-m/2}[F] \). On the other hand, we denote by \( [m/2] \) the cohomological degree shift by \( m/2 \in \frac{1}{2} \mathbb{Z} \). It will be convenient to use the notation \( \langle m/2 \rangle := [m/2]\{-m/2\} \) for the simultaneous shift and twist by \( m/2 \in \frac{1}{2} \mathbb{Z} \). This is the same notation as in [CW19].

### 3.3. Perverse coherent sheaves.

**Definition 3.1.** A \( GL_n(O) \times C^\times \)-equivariant perverse coherent sheaf on \( \text{Gr}_{GL_n} \) is an object \( F \in D_{coh}^{GL_n(O) \times C^\times}(\text{Gr}_{GL_n}) \) such that for every orbit \( i_\nu : \text{Gr}_{GL_n}^\nu \hookrightarrow \text{Gr}_{GL_n} \)

1. \( i_\nu^* F \in D_{coh}^{GL_n(O) \times C^\times}(\text{Gr}_{GL_n}^\nu) \) is supported in degrees \( \leq -\frac{1}{2} \dim \text{Gr}_{GL_n}^\nu \);
2. \( i_\nu^* F \in D_{coh}^{GL_n(O) \times C^\times}(\text{Gr}_{GL_n}^\nu) \) is supported in degrees \( \geq -\frac{1}{2} \dim \text{Gr}_{GL_n}^\nu \).

We denote by \( D_{coh}^{GL_n(O) \times C^\times}(\text{Gr}_{GL_n}) \subset D_{coh}^{GL_n(O) \times C^\times}(\text{Gr}_{GL_n}) \) the full subcategory of perverse coherent sheaves.
The category $P^{GL_n(O)}_{coh}(Gr_{GL_n})$ can be obtained as the core of a finite-length $t$-structure (called the \textit{perverse} $t$-\textit{structure}) of the category $P^{GL_n(O)}_{coh}(Gr_{GL_n})$ (cf. [AB10]). The convolution product $\ast$ preserves the category $P^{GL_n(O)}_{coh}(Gr_{GL_n})$ and the operation $(F, G) \mapsto F \ast G$ is bi-exact (cf. [BFM05]). Thus the equivariant $K$-group $K^{GL_n(O)}(Gr_{GL_n}) = K(P^{GL_n(O)}_{coh}(Gr_{GL_n}))$ becomes an algebra with a canonical $\mathbb{Z}$-basis formed by the classes of simple perverse coherent sheaves.

We say that $(\nu, \mu) \in P^\nu \times P$ is a dominant pair if $\nu \in P^\nu$ is a dominant coweight and $\mu \in P$ is dominant with respect to the Levi quotient of the stabilizer subgroup $Stab_{GL_n(O)[t^\nu]}$. More explicitly, the set $D_n$ of dominant pairs is given by

$$D_n = \left\{ (\nu, \mu) \in P^\nu \times P \left| \begin{array}{l}
\nu = (\nu_1, \ldots, \nu_n), \mu = (\mu_1, \ldots, \mu_n), \\
\mu_k \geq \mu_{k+1} \text{ whenever } \nu_k = \nu_{k+1}
\end{array} \right. \right\}.$$ 

To each dominant pair $(\nu, \mu) \in D_n$, we associate a simple perverse coherent sheaf $P_{\nu, \mu}$ in the following way. Note that the group

$$Stab_{GL_n(O)[t^\nu]}^{\text{red}}[t^\nu] := \{ g \in GL_n(\mathbb{C}) \mid g \cdot t^\nu = t^\nu \cdot g \} \cong \prod_k GL_{m_k}(\mathbb{C})$$

is a Levi subgroup of $Stab_{GL_n(O)[t^\nu]}$, where $m_k$ is the multiplicity of $k$ in the sequence $\nu \in \mathbb{Z}^n$. Then the group

$$Stab_{GL_n(O)[t^\nu]}^{\text{red}}[t^\nu] \times \mathbb{C}^\times = Stab_{GL_n(O)[t^\nu]}^{\text{red}}[t^\nu] \times \mathbb{C}^\times$$

is a Levi subgroup of $Stab_{GL_n(O)[t^\nu] \times \mathbb{C}^\times}$. Thus we can identify

$$\text{Irr} Stab_{GL_n(O)[t^\nu] \times \mathbb{C}^\times} = \text{Irr} Stab_{GL_n(O)[t^\nu]}^{\text{red}} \times \text{Irr} Stab_{GL_n(O)[t^\nu]}^{\text{red}},$$

where the set $\text{Irr} Stab_{GL_n(O)[t^\nu]}^{\text{red}}$ is regarded as a subset of $\text{Irr}(Stab_{GL_n(O)[t^\nu] \times \mathbb{C}^\times})$ consisting of representations with the trivial $\mathbb{C}^\times$-actions. Let $V_\mu$ denote the simple $GL_n(O) \times \mathbb{C}^\times$-equivariant vector bundle on $Gr_{GL_n}$ whose fiber at $[t^\nu]$ is isomorphic to $V_\mu$ as a representation of $Stab_{GL_n(O)[t^\nu]}$. We define the simple perverse coherent sheaf $P_{\nu, \mu}$ as the following (coherent) IC-extension (cf. [AB10, Theorem 4.2])

$$P_{\nu, \mu} := (i_\nu)_* V_\mu (\dim Gr_{GL_n}^{\nu}/2 \{ -\nu, \mu \}),$$

where $i_\nu : Gr_{GL_n}^{\nu} \hookrightarrow Gr_{GL_n}$ is the inclusion.

Since each simple perverse coherent sheaf is isomorphic to an IC-extension of a simple vector bundle on some $GL_n(O) \times \mathbb{C}^\times$-orbit (cf. [AB10, Proposition 4.11]), we have a bijection

$$D_n \times \mathbb{Z} \xrightarrow{1:1} \text{Irr} P^{GL_n(O) \times \mathbb{C}^\times}_{coh}(Gr_{GL_n}); \quad (\nu, \mu, m) \mapsto P_{\nu, \mu}(m/2).$$

In particular, the set

$$D_n := \{ [P_{\nu, \mu}] \mid (\nu, \mu) \in D_n \}$$

forms a $\mathbb{Z}[g^{1/2}]$-basis of the convolution ring $K^{GL_n(O) \times \mathbb{C}^\times}(Gr_{GL_n})$.

### 3.4. Lattice description

Recall that the affine Grassmannian $Gr_{GL_n}$ can be interpreted as the moduli space of $O$-lattices $L$ in $\mathbb{K}^n$. Let $L_0 := O^n \subset \mathbb{K}^n$ be the standard $O$-lattice. A coset $[g(t)] \in Gr_{GL_n} = GL_n(\mathbb{K})/GL_n(O)$ corresponds to a lattice $L = g(t)L_0$. Then for each $\nu \in P^\nu$ with $\nu_n \geq 0$, we have

$$Gr_{GL_n}^{\nu} = \{ L \subset L_0 \mid \text{type of } L \text{ is nilpotent of type } \nu \}.$$
In particular, when \( \nu = \omega_k \), we get
\[
\Gr^k_{GL_n} := \Gr^{\omega_k}_{GL_n} = \{ L \subset L_0 \mid tL_0 \subset L \},
\]
where \( L \subset L_0 \) indicates that \( \dim(L_0/L) = k \). In particular, \( \Gr^k_{GL_n} = \Gr^k_{GL_n} \) is isomorphic to the usual Grassmannian \( \Gr(k, n) \) of \( k \)-dimensional subspaces in \( \mathbb{C}^n \).

For each \( 1 \leq k \leq n \) and \( \ell \in \mathbb{Z} \), we put \( \mathcal{P}_{k, \ell} := \mathcal{P}_{\omega_k, \ell \omega_k} \) for simplicity. Using the above description of \( \Gr^k_{GL_n} \), we see
\[
\mathcal{P}_{k, \ell} = i_{\omega_k*} \left( \mathcal{O}_{\Gr^k_{GL_n}} \otimes \det(L_0/L)^\ell \right) \langle k(n - k)/2 \rangle \langle -k\ell \rangle,
\]
where we denote by \( L_0/L \) the vector bundle on \( \Gr^k_{GL_n} \) whose fiber at \( L \) is equal to \( L_0/L \) by an abuse of notation.

3.5. Cautis-Williams’ monoidal categorification theorem. In [CW19], Cautis and Williams proved that, for a general complex reductive group \( G \), the category of \( G(\mathcal{O}) \times \mathbb{C}^\times \)-equivariant perverse coherent sheaves is a rigid monoidal category, i.e. every object \( \mathcal{F} \) has its left and right duals. Moreover, they also proved the existence of a system of renormalized \( r \)-matrices (originated in the settings of the quiver Hecke algebras and the quantum affine algebras, see [KKKO18] for instance), which informally encodes some information about how the category fails to be a braided tensor category. Using these facts, it was successfully proved in the case \( G = GL_n \) that the monoidal category \( P^\text{GL}_n(\mathcal{O}) \times \mathbb{C}^\times (\Gr_{GL_n})_\text{coh} \) categorifies the quantum unipotent cell \( \mathcal{A}^\text{loc}_n \). More precisely, we have:

**Theorem 3.2** (Cautis-Williams [CW19]). There exists an isomorphism of \( \mathbb{Z}[q^{\pm 1/2}] \)-algebras
\[
\Phi : \mathcal{A}^\text{loc}_n \cong K^\text{GL}_n(\mathcal{O}) \times \mathbb{C}^\times (\Gr_{GL_n}),
\]
which sends each cluster monomial to the class of a simple perverse coherent sheaf. Moreover, for each \( 1 \leq b \leq d \leq 2n \) with \( d - b \in 2\mathbb{Z} \), we have \( \Phi(\widetilde{D}[b, d]) = [\mathcal{P}_{k, \ell}] \) with
\[
k = 1 + \frac{1}{2}(d - b), \quad \ell = n + 1 - \frac{1}{2}(b + d).
\]
In particular, we have
\[
\Phi(\widetilde{E}(\beta_k)) = \Phi(\widetilde{D}[k, k]) = [\mathcal{P}_{1, n+1-k}]
\]
for each \( 1 \leq k \leq 2n \).

The bar involution \( \iota \) of \( \mathcal{A}^\text{loc}_n \) was also categorified in [CW19, Section 6.2]. Let \( \sigma_1 \) be the group involution of \( GL_n(\mathcal{O}) \times \mathbb{C}^\times \) given by \( (g(t), a) \mapsto (g(t)^{-1}, a) \), where \( \mathbb{T}(-) \) denotes the transpose of matrices. Then the morphism
\[
\eta : \Gr_{GL_n} \to GL_n(\mathcal{K}) \times GL_n(\mathcal{O}) (\Gr_{GL_n})^{\sigma_1} = (GL_n(\mathcal{K}) \times \mathbb{C}^\times \times (GL_n(\mathcal{O}) \times \mathbb{C}^\times) \times (\Gr_{GL_n})^{\sigma_1}
\]
defined by \( \eta([g(t)]) := [g(t), \mathbb{T}[g(t)] \rangle \) becomes \( GL_n(\mathcal{O}) \times \mathbb{C}^\times \)-equivariant. We define an involutive auto-equivalence \( \iota \) on \( D^\text{GL}_n(\mathcal{O}) \times \mathbb{C}^\times (\Gr_{GL_n}) \) by
\[
\iota(\mathcal{F}) := D \circ L \circ \eta^* (\mathcal{O}_{\Gr_{GL_n}} \boxtimes \mathcal{F}^{\sigma_1}),
\]
where \( D \) is the Grothendieck-Serre duality functor and \( L \) is an auto-equivalence on \( D^\text{GL}_n(\mathcal{O}) \times \mathbb{C}^\times (\Gr_{GL_n}) \) which, on the \( d \)-th component \( \Gr_{GL_n}^{(d)} \), acts by tensoring with
\[
\mathcal{O}_{\Gr_{GL_n}}(-n) \otimes \det(L_0/tL_0)^d \{ d(n - d) \}.
\]
Theorem 3.3 ([CW19, Corollary 6.24 & 6.25]). The involution $\iota$ is contravariant with respect to both convolution product $*$ and Hom, preserves the category of perverse coherent sheaves and satisfies $\iota(\mathcal{P}_{\nu,\mu}(m/2)) \cong \mathcal{P}_{\nu,\mu}(-m/2)$ for any $(\nu, \mu) \in \mathcal{D}_n$ and $m/2 \in \frac{1}{2}\mathbb{Z}$. Therefore, for any $\xi \in \mathcal{A}_n^{loc}$, we have $\Phi(\iota \xi) = \iota \Phi(\xi)$.

Note that the basis $\mathcal{P}_n$ of $K^{GL_n(O) \times \mathbb{C}^\times}(Gr_{GL_n})$ is nothing but the subset formed by the classes of $\iota$-selfdual simple perverse coherent sheaves.

4. Comparison with nilpotent cones of type $A$

4.1. Main result. The main theorem of this paper is the following.

Theorem 4.1. Under Cautis-Williams’ isomorphism $\Phi: \mathcal{A}_n^{loc} \cong K^{GL_n(O) \times \mathbb{C}^\times}(Gr_{GL_n})$ in Theorem 3.2, the dual canonical basis $\mathcal{P}_n^{dual}$ of $\mathcal{A}_n^{loc}$ bijectively corresponds to the basis $\mathcal{P}_n$ of $K^{GL_n(O) \times \mathbb{C}^\times}(Gr_{GL_n})$ formed by the classes of $\iota$-selfdual simple perverse coherent sheaves.

By Theorem 3.2, we have $\Phi(D_0) = [P_{n,1}]$ and $\Phi(D_1) = [P_{n,0}]$. Since both $P_{n,0}$ and $P_{n,1}$ are invertible objects of the monoidal category $P^{GL_n(O) \times \mathbb{C}^\times}_{coh}(Gr_{GL_n})$, the operations $- \circ [P_{n,0}]_{\pm 1}$ and $- \circ [P_{n,1}]_{\pm 1}$ induce the self-bijections of the set $\mathcal{P}_n$. Therefore, to verify Theorem 4.1, it suffices to prove the following simpler assertion:

Theorem 4.2. We have $\Phi(B(a)) \in \mathcal{P}_n$ for any $a \in \mathbb{N}^{2n}$.

A proof will be given in the end of Section 4.3.

Remark 4.3. When $n = 2$, Theorem 4.1 can be verified directly by using an explicit computation of the dual canonical basis of the quantum unipotent group $A_2$ due to Lampe [L14].

4.2. Perverse coherent sheaves on the nilpotent cone. Fix $d \in \mathbb{N}$. Let

$$N^d := \{x \in \text{End}(\mathbb{C}^d) \mid x^d = 0 \}$$

be the nilpotent cone of $\mathfrak{gl}_d(\mathbb{C})$. A left action of the group $GL_d(\mathbb{C}) \times \mathbb{C}^\times$ on $N^d$ is given by $(g, a) \cdot x = a^{-d} \text{Ad}(g)x$. The equivariant $K$-group $K^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}(N^d)$ is a module over $\mathbb{Z}[q^{\pm 1/2}]$, where $q^{m/2} \in K^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}(pt)$ denotes the class of the pullback of the 1-dimensional $\mathbb{C}^\times$-module $\mathbb{C}_m$ of weight $m$ along the natural projection $GL_d(\mathbb{C}) \times \mathbb{C}^\times \to \mathbb{C}^\times$.

Recall that the nilpotent cone $N^d$ has a finite number of $GL_d(\mathbb{C})$-orbits ($= GL_d(\mathbb{C}) \times \mathbb{C}^\times$-orbits) which are parametrized by the set $P(d)$ of partitions of $d$. The orbit $O_\nu$ labelled by a partition $\nu = (\nu_1 \geq \nu_2 \geq \cdots) \in P(d)$ consists of nilpotent matrices of Jordan type $\nu$, i.e. whose Jordan normal form is

$$J_\nu := J_{\nu_1} \oplus J_{\nu_2} \oplus \cdots,$$

where $J_m := \begin{pmatrix} 0 & & & \\ 1 & 0 & & \\ & 1 & 0 & \\ & & \ddots & \\ & & & 1 & 0 \end{pmatrix} \in \mathfrak{gl}_m(\mathbb{C})$.

We can easily compute $\dim O_\nu = d^2 - \sum_{i \geq 1} (2i-1)\nu_i$ and $\text{codim} O_\nu = \dim N^d - \dim O_\nu = \sum_{i \geq 1} (2i-1)\nu_i - d$, both of which are even numbers.

We can consider the $GL_d(\mathbb{C}) \times \mathbb{C}^\times$-equivariant perverse coherent sheaves on the nilpotent cone $N^d$. 
**Definition 4.4.** A $GL_d(\mathbb{C}) \times \mathbb{C}^\times$-equivariant perverse coherent sheaf on $\mathcal{N}^d$ is an object $F \in D^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}_\text{coh}(\mathcal{N}^d)$ such that for every orbit $j_\nu : O_\nu \hookrightarrow \mathcal{N}^d$

1. $j_\nu^* F \in D^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}_\text{coh}(\mathcal{N}^d)$ is supported in degrees $\leq \frac{1}{2}$ codim $O_\nu$;
2. $j_\nu^* F \in D^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}_\text{coh}(\mathcal{N}^d)$ is supported in degrees $\geq \frac{1}{2}$ codim $O_\nu$.

We denote by $P^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}_\text{coh}(\mathcal{N}^d) \subset D^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}_\text{coh}(\mathcal{N}^d)$ the full subcategory of perverse coherent sheaves.

The simple perverse coherent sheaves are parametrized by the set

$$O_d := \{(\nu, V) \mid \nu \in P(d), V \in \text{Irr}_{GL_d(\mathbb{C})}(J_\nu)\}$$

up to isomorphism and $\mathbb{C}^\times$-equivariant twist in the following way (cf. [AH19, Section 3]). For each partition $\nu = (\nu_1, \nu_2, \ldots) \in P(d)$, we define a homomorphism $\phi_\nu : \mathbb{C}^\times \to GL_d(\mathbb{C})$ by

$$\phi_\nu(a) := \phi_{\nu_1}(a) \oplus \phi_{\nu_2}(a) \oplus \cdots,$$

where $\phi_{\nu_i}(a) := \text{diag}(a^{2(-m+1)}, a^{2(-m+3)}, \ldots, a^{2(m-1)}) \in GL_{\nu_i}(\mathbb{C})$. The homomorphism $\phi_\nu$ is a cocharacter associated to the nilpotent element $J_\nu$ in the sense of [J04, Section 5.3]. In particular, we have $\text{Ad}(\phi_\nu(a))J_\nu = a^4 J_\nu$, and the group

$$\text{Stab}_{GL_d(\mathbb{C})}(J_\nu) := \{g \in \text{Stab}_{GL_d(\mathbb{C})}(J_\nu) \mid g\phi_\nu(a) = \phi_\nu(a)g, \forall a \in \mathbb{C}^\times\}$$
is a Levi subgroup of $\text{Stab}_{GL_d(\mathbb{C})}(J_\nu)$. Then the image of the group embedding

$$\text{Stab}_{GL_d(\mathbb{C})}^r(\nu, V) = \text{Stab}_{GL_d(\mathbb{C})}^r(J_\nu) \times \mathbb{C}^\times \hookrightarrow \text{Stab}_{GL_d(\mathbb{C})}(J_\nu) ; (g, a) \mapsto (g\phi_\nu(a), a)$$
is a Levi subgroup. Via this embedding, we make an identification

$$\text{Irr}(\text{Stab}_{GL_d(\mathbb{C})}(J_\nu)) = \text{Irr} \text{Stab}_{GL_d(\mathbb{C})}^r(J_\nu) \subset \text{Irr} \text{Stab}_{GL_d(\mathbb{C})}^r(J_\nu),$$

where the set $\text{Irr}(\text{Stab}_{GL_d(\mathbb{C})}^r(J_\nu))$ is regarded as a subset of $\text{Irr} \text{Stab}_{GL_d(\mathbb{C})}^r(J_\nu)$ consisting of representations with the trivial $\mathbb{C}^\times$-actions. For a pair $(\nu, V) \in O_d$, let $V$ be the simple $GL_d(\mathbb{C}) \times \mathbb{C}^\times$-equivariant vector bundle on $O_\nu$ whose fiber at $J_\nu$ is isomorphic to $V$ as a representation of $\text{Stab}_{GL_d(\mathbb{C})}(J_\nu)$. We define the simple perverse coherent sheaf $\mathcal{C}_{\nu, V}$ as the following (coherent) IC-extension

$$\mathcal{C}_{\nu, V} := \{(j_\nu)_* m / \text{codim} O_\nu/2, \}$$

where $j_\nu : O_\nu \hookrightarrow \mathcal{T}_\nu$ is the inclusion.

Under the above notation, we have a bijection

$$O_d \times \mathbb{Z} \xrightarrow{1:1} \text{Irr} D^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}_\text{coh}(\mathcal{N}^d) ; (\nu, V, m) \mapsto \mathcal{C}_{\nu, V} \{m/2\},$$

Thus the set $\{\mathcal{C}_{\nu, V} \mid (\nu, V) \in O_d\}$ forms a $\mathbb{Z}[a^\pm 1/2]$-basis of $K^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}(\mathcal{N}^d)$.

Next we introduce another basis of $K^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}(\mathcal{N}^d)$. Let $B_d \subset GL_d(\mathbb{C})$ be the Borel subgroup consisting of invertible lower triangular matrices and $B^-_d := GL_d(\mathbb{C})/B_d$ be the flag variety. The cotangent bundle $T^*B_d$ is naturally identified with the space $GL_d(\mathbb{C}) \times B^-_d n_d$, where $n_d \subset gl_d(\mathbb{C})$ is the Lie algebra of strictly lower triangular matrices (= the nilpotent radical of $\text{Lie}(B_d)$). Let $\pi : T^*B_d \to B_d$ denote the natural projection $[g, x] \mapsto [g]$ and $\text{Sp} : T^*B_d \to \mathcal{N}^d$ denote the Springer resolution $[g, x] \mapsto \text{Ad}(g)x$. A natural left $GL_d(\mathbb{C}) \times \mathbb{C}^\times$-action on $T^*B_d$ is given by $(h, a) \cdot [g, x] := [hg, a^{-4}x]$. Both morphisms $\pi$ and $\text{Sp}$ are $GL_d(\mathbb{C}) \times \mathbb{C}^\times$-equivariant.

Let $T_d \subset B_d$ be the maximal torus consisting of diagonal matrices. As before, the weight lattice $X := \text{Hom}(T_d, \mathbb{C}^\times) = \text{Hom}(B_d, \mathbb{C}^\times)$ is identified with $\mathbb{Z}^d$. For any
\( \lambda \in X \), we denote by \( O_{B_d}(\lambda) \) the corresponding line bundle \( GL_d(\mathbb{C}) \times B_d \lambda \) on \( B_d \), which is regarded as a \( GL_d(\mathbb{C}) \times \mathbb{C}^\times \)-equivariant bundle with the trivial \( \mathbb{C}^\times \)-action. We define the corresponding \textit{Andersen-Jantzen sheaf} \( AJ(\lambda) \) by

\[
AJ(\lambda) := \mathfrak{Sp}_* \pi^* O_{B_d}(\lambda).
\]

More precisely, \( \mathfrak{Sp}_* \) denotes the derived push forward and the Andersen-Jantzen sheaf \( AJ(\lambda) \) is an object of \( D^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}_{coh}(\mathcal{N}^d) \) (which may or may not be a genuine sheaf).

As a convention, we regard the weights of \( \mathfrak{n}_d \) as the negative roots. Then the set of dominant weights is \( X_+ = \{ \lambda = (\ell_1, \ldots, \ell_d) \in X \mid \ell_1 \geq \cdots \geq \ell_d \} \).

For each dominant weight \( \lambda \in X_+ \), we define

\[
\Delta_\lambda := AJ(w_0 \lambda)\{\delta_\lambda\}, \quad \nabla_\lambda := AJ(\lambda)\{-\delta_\lambda\}
\]

where \( w_0 \) is the longest element of the Weyl group \( \mathfrak{S}_d \) of \( GL_d(\mathbb{C}) \) and \( \delta_\lambda := \min \{ \ell(w) \mid w \in \mathfrak{S}_d, w\lambda \in -X_+ \} \). Explicitly we have

\[
(4.1) \quad \delta_\lambda = \frac{1}{2} (d(d-1) - \sum_k m_k (m_k - 1)),
\]

where \( m_k \) is the multiplicity of \( k \in \mathbb{Z} \) in the sequence \( \lambda \in \mathbb{Z}^d \).

It is known that both objects \( \Delta_\lambda \) and \( \nabla_\lambda \) are perverse coherent sheaves. Indeed the family \( \{ \nabla_\lambda \mid \lambda \in X_+ \} \) forms a quasi-exceptional set of the category \( D^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}_{coh}(\mathcal{N}^d) \) with \( \{ \Delta_\lambda \mid \lambda \in X_+ \} \) being its dual, which yields the above perverse \( t \)-structure (cf. [B03]). In particular, there is a canonical morphism \( \Delta_\lambda \to \nabla_\lambda \) for each \( \lambda \in X_+ \). We denote the image of this canonical morphism by \( \xi_\lambda \), which is a simple perverse coherent sheaf. The following result due to Achar-Hardesty [AH19] is the graded (or \( \mathbb{C}^\times \)-equivariant) version of the \textit{Lusztig-Vogan bijection}. The non-graded version was originally established by [A01] (for \( GL_d \)) and [B03] (for a general reductive group instead of \( GL_d \)).

**Theorem 4.5** ([AH19, Theorem 4.5]). There is a bijection

\[
LV : X_+ \overset{\sim}{\to} O_d
\]

such that we have \( \xi_\lambda \cong C_{LV(\lambda)} \) for any \( \lambda \in X_+ \).

We define the modified Grothendieck-Serre duality functor \( D_{\mathcal{N}^d} \) on \( \mathcal{N}^d \) by

\[
D_{\mathcal{N}^d} := R \mathcal{H}om(-, O_{\mathcal{N}^d}).
\]

**Remark 4.6.** The usual Grothendieck-Serre duality is defined by using the dualizing complex. The dualizing complex \( \omega_{\mathcal{N}^d} \) of the nilpotent cone \( \mathcal{N}^d \) is \( O_{\mathcal{N}^d}(d(d-1)) \) (see [AH19, Proposition 2.4]).

Let \( \sigma \) be an involution of the group \( GL_d(\mathbb{C}) \times \mathbb{C}^\times \) given by \( (h, a) \mapsto (h^{-1}, a) \). Then the transpose map \( x \mapsto ^tx \) induces a \( GL_d(\mathbb{C}) \times \mathbb{C}^\times \)-equivariant isomorphism \( \tau : \mathcal{N}^d \overset{\sim}{\to} (\mathcal{N}^d)^\sigma \). We define an involutive auto-equivalence \( \iota \) of \( P^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}_{coh}(\mathcal{N}^d) \) by

\[
\iota(F) := D_{\mathcal{N}^d} \circ \tau^*(F^\sigma).
\]

Then we have \( \iota(q^{1/2}) = q^{-1/2} \) at the level of Grothendieck group. The following theorem was originally conjectured by Ostrick [O00] and proved by Bezrukavnikov (see [B03, Introduction]).
Theorem 4.7 (Bezrukavnikov). The $\mathbb{Z}[q^{±1/2}]$-basis $\{[\mathcal{C}_\lambda] \mid \lambda \in X_+\}$ of $K^{GL_n(C) \times C^\times} \langle N^d \rangle$ is characterized by the following properties:

1. $t[\mathcal{C}_\lambda] = [\mathcal{C}_\lambda]$;
2. $[\mathcal{C}_\lambda] \in [\nabla \lambda] + \sum_{\lambda' \in X_+} q^{-1} \mathbb{Z}[q^{-1}][\nabla \lambda']$.

4.3. Comparison with the nilpotent cone. Towards a proof of Theorem 4.2, let us compare $P_{coh}^{GL_n(O) \times C^\times}(Gr_{GL_n})$ with $P_{coh}^{GL_n(C) \times C^\times} \langle N^d \rangle$. Fix two positive integers $n, d \in \mathbb{N}$ and consider the Schubert variety

$$Gr^d_n := \overline{\mathcal{O}_{GL_n} \langle d \rangle} = \{ L \subset L_0 \mid \dim(L_0/L) = d \}.$$ 

This is a finite union of $GL_n(O)$-orbits $Gr^\nu_{GL_n}$ where $\nu$ runs over the set

$$P_n(d) := \{ \nu = (\nu_1, \ldots, \nu_n) \in \mathbb{Z}^n \mid \nu_1 \geq \cdots \geq \nu_n \geq 0, \nu_1 + \cdots + \nu_n = d \}$$ 

of partitions of $d$ of length $\leq n$, regarded as dominant coweights of $GL_n$ in the same way as before. Let $D_{n,d}$ be the set of dominant pairs $(\nu, \mu) \in D_n$ with $\nu \in P_n(d)$. Then the set $\{ [P_{\nu,\mu}] \mid (\nu, \mu) \in D_{n,d} \}$ forms a $\mathbb{Z}[q^{±1/2}]$-basis of $K^{GL_n(O) \times C^\times} \langle N^d \rangle$.

We define the modified Grothendieck-Serre duality functor $\mathbb{D}_{Gr^d_n}$ on $Gr^d_n$ by

$$\mathbb{D}_{Gr^d_n} := \mathcal{RHom}(-, O_{Gr^d_n})(d(n-1)).$$

Remark 4.8. The dualizing complex of the Schubert variety $Gr^d_n$ is isomorphic to

$$\mathcal{O}_{Gr_{GL_n}}(-n) \otimes \det(L_0/tL_0)^d \langle d(n-1) \rangle$$

(see [CW19, Lemma 6.20]). Therefore we have

$$(4.2) \quad \mathbb{D}_{Gr^d_n}(\mathcal{F}) = \mathbb{D} \circ L(\mathcal{F})$$

for any $\mathcal{F} \in D_{coh}^{GL_n(O) \times C^\times}(Gr^d_n)$ (see Section 3.5 for the definition of $L$).

Under the above notation, we have the following morphism of quotient stacks:

$$\psi : [(GL_n(O) \times C^\times) \backslash Gr^d_n] \rightarrow [(GL_d(C) \times C^\times) \backslash N^d] : (L \subset L_0) \rightarrow t| \mathcal{O}_{Gr^d_n}.$$ 

Lemma 4.9. The morphism $\psi$ is formally smooth.

Proof. For a fixed $d$ and $N \gg 0$, $Gr^d_n = \{ L : L_0 \supset L \supset t^NL_0 \}$. We have an evident morphism $[(GL_n(O/t^N O) \times C^\times) \backslash Gr^d_n] \rightarrow [(GL_n(O) \times C^\times) \backslash Gr^d_n]$, and by an abuse of notation we will denote by $\psi : [(GL_n(O/t^N O) \times C^\times) \backslash Gr^d_n] \rightarrow [(GL_d(C) \times C^\times) \backslash N^d]$ the composition of the former $\psi$ with the above evident morphism. It suffices to prove that the new $\psi$ is smooth. Moreover, we will keep the same notation $\psi$ for the similar morphism $[GL_n(O/t^N O) \backslash Gr^d_n] \rightarrow [Gr^d_n] \langle N^d \rangle$ (disregarding the extra $C^\times$-equivariance). It suffices to prove that the latter $\psi$ is smooth.

Given an affine test scheme $S = \text{Spec} \, A$ along with its nilpotent extension $\tilde{S} = \text{Spec} \, \tilde{A}$, $A = \tilde{A}/I$, and a morphism $\varphi : S \rightarrow (GL_n(O/t^N O) \backslash Gr^d_n)$ along with an extension

$$\tilde{\varphi} : \tilde{S} \rightarrow [GL_d(C) \backslash N^d] \quad \text{of} \quad \varphi := \psi \circ \tilde{\varphi} : S \rightarrow [GL_d(C) \backslash N^d]$$

we have to find an extension $\tilde{\varphi} : \tilde{S} \rightarrow [GL_n(O/t^N O) \backslash Gr^d_n]$.

We may and will assume that $A$ and $\tilde{A}$ are local, hence the projective modules are free. Then an $S$-point $\varphi$ is a free $A$-module $M$ of rank $d$ with a nilpotent endomorphism $t \in \text{End}_A(M)$. Similarly, an $\tilde{S}$-point $\tilde{\varphi}$ is a free $\tilde{A}$-module $\tilde{M}$ of rank $d$ with a nilpotent endomorphism $\tilde{t} \in \text{End}_{\tilde{A}}(\tilde{M})$. An $S$-point $\varphi$ is a free $A$-module $M$ of rank $nN$ with a nilpotent endomorphism $t$ “of Jordan type $N^n$” and
a \mathfrak{t}$-invariant (locally) free $A$-submodule $M' \subset M$ such that the quotient $M/M'$ is free of rank $d$. Finally, an $\tilde{t}$-point $\tilde{\varphi}$ is a free $A$-module $\tilde{M}$ of rank $nN$ with a nilpotent endomorphism $\tilde{t}$ of Jordan type $N^*$ and a $\mathfrak{t}$-invariant (locally) free $\tilde{A}$-submodule $\tilde{M}' \subset \tilde{M}$ such that the quotient $\tilde{M}/\tilde{M}'$ is free of rank $d$.

We have to prove that given $(\tilde{M}, \tilde{t})$ and $(M', t)$ as above giving rise to the same $(\tilde{M}/I, \tilde{t} \bmod I) = (M, t)$, there exists $(M' \subset \tilde{M}, \tilde{t})$ as above such that $(\tilde{M}' \bmod I) \subset \tilde{M} \bmod I$ (mod $\tilde{t}$), while $(\tilde{M}/\tilde{M}', \tilde{t} \bmod I) = (M, t)$. If we disregard the nilpotent operators, then the existence of the desired extension $\tilde{M}' \subset \tilde{M}$ follows from the smoothness of the evident morphism $GL_{nN} \setminus Gr(d, nN) \rightarrow GL_d \setminus \text{pt}$ (and is evident by itself).

So it remains to prove that the sequence

$$\text{End}_A(\tilde{M}' \subset \tilde{M}) \rightarrow \text{End}_A(\tilde{M}) \oplus \text{End}_A(M' \subset M) \rightarrow \text{End}_A(M)$$

(see the diagram below) is exact in the middle term:

\[
\begin{array}{ccc}
\text{End}_A(\tilde{M}) & \rightarrow & \text{End}_A(\tilde{M}' \subset \tilde{M}) \\
\downarrow & & \downarrow \\
\text{End}_A(M) & \rightarrow & \text{End}_A(M' \subset M).
\end{array}
\]

This is clear since all our modules are free, and moreover, we can find a complementary free submodule $\tilde{M}'' \subset \tilde{M}$ such that $\tilde{M} = \tilde{M}'' \oplus \tilde{M}'$.

**Corollary 4.10.** The morphism $\psi: [(GL_n(O) \times \mathbb{C}^*) \setminus Gr^n] \rightarrow [(GL_d(O) \times \mathbb{C}^*) \setminus N^d]$ is flat.

**Proof.** This is [EGA IV, Théorème 17.5.1].

Therefore the pull-back along $\psi^*$ induces a triangulated functor

$$\psi^*: D_{coh}^{GL_d(O) \times \mathbb{C}^*}(N^d) \rightarrow D_{coh}^{GL_n(O) \times \mathbb{C}^*}(Gr^n).$$

In what follows, we restrict ourselves to the open subvariety

$$N^d_n := \bigsqcup_{\nu \in P_n(d)} O_{\nu} \subset N^d.$$

Let $O_{n, d}$ be the set of pairs $(\nu, V) \in O_d$ with $\nu \in P_n(d)$. Then the set $\{[C_{\nu, V}] \mid (\nu, V) \in O_{n, d}\}$ forms a $\mathbb{Z}[q^{1/2}]$-basis of $K^{GL_d(O) \times \mathbb{C}^*}(N^d_n)$. We will keep the same notation $AJ(\lambda), \Delta, \nabla_{\lambda}$ for their restrictions to $N^d_n$.

By construction, the morphism $\psi$ has its image in the open substack $[(GL_d(O) \times \mathbb{C}^*) \setminus N^d_n]$. More precisely, for each $\nu \in P_n(d)$, the morphism $\psi$ sends the $GL_n(O)$-orbit $Gr^n_{\nu}$ to the $GL_d(O)$-orbit $O_{\nu}$. Thus we have obtained the triangulated functor:

$$\psi^*: D_{coh}^{GL_d(O) \times \mathbb{C}^*}(N^d_n) \rightarrow D_{coh}^{GL_n(O) \times \mathbb{C}^*}(Gr^n).$$

**Definition 4.11.** We define the triangulated functor

$$\Psi: D_{coh}^{GL_d(O) \times \mathbb{C}^*}(N^d_n) \rightarrow D_{coh}^{GL_n(O) \times \mathbb{C}^*}(Gr^n) \quad \text{by} \quad \Psi(-) := \psi^*(-)(d(n-1)/2).$$

**Proposition 4.12.** The functor $\Psi$ satisfies the following properties:
Lemma 4.9, it suffices to show that given a local $C$-morphism $\psi$ (see Remark 4.8).

The morphisms $\psi$ here are known to be cohomological degree shifts of an invertible sheaf $d$, the dualizing complex of $Gr^n$ yields a surjective map $\psi$.

\[ \Psi: \mathcal{P}^{GL_d(C) \times C^x}(N^n_d) \rightarrow \mathcal{P}^{GL_n(O) \times C^x}(Gr^n_d); \]

(2) $\Psi$ is compatible with the IC-extensions, i.e. for any $\nu \in P_n(d)$, we have $\Psi \circ (j_\nu)_* \simeq (i_\nu)_* \circ \Psi$.

(3) $\Psi$ is compatible with the duality functors, i.e. we have $\Psi \circ D_{N^n_d} \simeq D_{Gr^n_d} \circ \Psi$.

**Proof.** Note that the cohomological degree shift $[d(n-1)/2]$ in the definition of $\Psi$ arises from the fact that $d(n-1) = \text{codim} O_\nu + \dim Gr^n_d$ for any $\nu \in P_n(d)$.

For (1), we apply [AB10, Lemma 3.4]. To do so, we have to check that the morphism $\psi$ is faithfully flat and Gorenstein. For the faithful flatness, thanks to Lemma 4.9, it suffices to show that given a local $C$-algebra $A$ the morphism $\psi$ yields a surjective map $[(GL_n(O) \times C^x) \backslash Gr^n_d](A) \rightarrow [(GL_d(C) \times C^x) \backslash N^n_d](A)$ of the sets of $A$-points. (Or instead, we may show that the morphism $\psi_2: \mathcal{M}^d_n \rightarrow N^n_d$ defined below is surjective as a morphism between the schemes associated with the varieties.) This can be proved easily by the definition of $N^n_d$. For the Gorenstein property, it suffices to show that $\psi^! O_{N^n_d}$ is a cohomological degree shift of an invertible sheaf (see [H66, Exercise V.9.5]). Since the dualizing complex of $N^n_d$ is isomorphic to $O_{N^n_d}(d(d-1))$ (see Remark 4.6), the sheaf $\psi^!(O_{N^n_d})$ is isomorphic to the dualizing complex of $Gr^n_d$ up to cohomological degree shift and $C^x$-equivariant twist, which is also known to be a cohomological degree shift of an invertible sheaf (see Remark 4.8).

Now (2) can be proved in a similar way by the definition of the minimal extension functors. See [AB10, Theorem 4.2].

The remaining assertion (3) follows from Remarks 4.6 & 4.8 and the fact

$$\psi^1(-) = \psi^*(-) \otimes \omega_{Gr^n_d/N^n_d} = (L \circ \psi^*)(-)(d(d-n)).$$

See [H66, Remark on pp. 143–144] for the first equality.

For a technical reason, we will introduce an auxiliary space. Let $\mathcal{M}^d_n$ be the variety of pairs $(L, \gamma)$ such that:

(i) $L$ is a $O$-lattice of $K^n$ such that $\dim L_0/L = d$;

(ii) $\gamma$ is a $C$-linear isomorphism $\gamma: L_0/L$.

We equip the space $\mathcal{M}^d_n$ with a left action of the group $GL_d(C) \times GL_n(O) \times C^x$ by

$$(h, g(t), a) \cdot (L, \gamma) := ((g(t), a)L, (g(t), a) \circ \gamma \circ h^{-1}),$$

where $h \in GL_d(C)$, $g(t) \in GL_n(O)$, $a \in C^x$ and in the 2nd entry of the right hand side the element $(g(t), a) \in GL_n(O) \times C^x$ is regarded as a $C$-linear isomorphism $L_0/L \sim L_0/(g(t), a)L$. Then we can consider the following diagram:

$$Gr^n_d \xleftarrow{\psi_1} \mathcal{M}^d_n \xrightarrow{\psi_2} N^n_d.$$

Here the morphism $\psi_1$ is the first projection $\langle L, \gamma \rangle \mapsto L$ and the morphism $\psi_2$ is given by

$$(L, \gamma) := \gamma^{-1} \circ f|L_0/L \circ \gamma.$$
bundle, the pull-back functor gives an equivalence of triangulated categories:
\[ \psi^*_1 : D^\text{coh}_{\text{coh}}(\mathcal{O} \times \mathbb{C}^\times) (\mathcal{M}_n^d) \cong D^\text{coh}_{\text{coh}}(\mathcal{O} \times \mathbb{C}^\times) (\text{Gr}^d_n). \]
We fix a quasi-inverse of \( \psi^*_1 \) and denote it by \( (\psi^*_1)^{-1} \).

**Lemma 4.13.** There is an isomorphism of functors \( \psi^* \cong (\psi^*_1)^{-1} \circ \psi_2^* \).

**Proof.** This is obvious from the construction. \( \square \)

For each \( \nu = (\nu_1, \ldots, \nu_n) \in P_n(d) \), we define a \( \mathbb{C} \)-linear isomorphism
\[ \gamma_\nu : \mathbb{C}^d \xrightarrow{\sim} L_0 / (t^\nu L_0) \] for each \( 1 \leq k \leq n \) and \( \nu_1 + \cdots + \nu_k < j \leq \nu_1 + \cdots + \nu_k, \) where \( \{ v_j \in \mathbb{C}^d \mid 1 \leq j \leq d \} \) is the standard \( \mathbb{C} \)-basis of \( \mathbb{C}^d \) and \( \{ u_k \in \mathbb{C}^n \mid 1 \leq k \leq n \} \) is the standard \( \mathbb{K} \)-basis of \( \mathbb{K}^n \). The point \( p_\nu := (t^\nu L_0, \gamma_\nu) \in \mathcal{M}_n^d \) satisfies \( \psi_1(p_\nu) = [t^\nu] \) and \( \psi_2(p_\nu) = J_\nu \). Then the natural projections
\[ GL_n(\mathcal{O}) \times \mathbb{C}^\times \xleftarrow{\psi} GL_d(\mathbb{C}) \times GL_n(\mathcal{O}) \times \mathbb{C}^\times \rightarrow GL_d(\mathbb{C}) \times \mathbb{C}^\times \]
induce the homomorphisms of stabilizers
\[ \text{Stab}_{GL_n(\mathcal{O}) \times \mathbb{C}^\times} [t^\nu] \xleftarrow{\psi} \text{Stab}_{GL_d(\mathbb{C}) \times GL_n(\mathcal{O}) \times \mathbb{C}^\times} (p_\nu) \rightarrow \text{Stab}_{GL_d(\mathbb{C}) \times \mathbb{C}^\times} (J_\nu), \]
where the left one is an isomorphism because \( \psi_1 \) is a \( GL_d(\mathbb{C}) \)-bundle. Let
\[ \rho : \text{Stab}_{GL_n(\mathcal{O}) \times \mathbb{C}^\times} [t^\nu] \rightarrow \text{Stab}_{GL_d(\mathbb{C}) \times \mathbb{C}^\times} (J_\nu) \]
be the group homomorphism obtained by composing the above homomorphisms. This homomorphism \( \rho \) induces an isomorphism between the subgroups
\[ \rho_1 : \text{Stab}^\text{red}_{GL_n(\mathcal{O})} [t^\nu] \xrightarrow{\sim} \text{Stab}^\text{red}_{GL_d(\mathbb{C})} (J_\nu). \]

In particular, the assignment \( (\nu, \mu) \mapsto (\nu, V_\mu) \) defines a bijection \( D_{n,d} \xrightarrow{\sim} O_{n,d}. \) Henceforth we identify \( O_{n,d} \) with \( D_{n,d} \) via this bijection and we write \( C_{\nu, \mu} \) instead of \( C_{\nu, V_\mu}. \)

**Lemma 4.14.** For any \( (\nu, \mu) \in D_{n,d} \), we have an isomorphism
\[ \Psi \left( C_{\nu, \mu} \{ -\langle \omega_n, \mu \rangle \} \right) \cong P_{\nu, \mu}. \]
In particular, the functor \( \Psi \) induces an isomorphism\(^1\) of \( \mathbb{K} \)-groups
\[ [\Psi] : K^{GL_d(\mathbb{C}) \times \mathbb{C}^\times} (\mathcal{N}_n^d) \cong K^{GL_n(\mathcal{O}) \times \mathbb{C}^\times} (\text{Gr}^d_n), \]
which gives a bijective correspondence between the classes of simple perverse coherent sheaves.

**Proof.** By Proposition 4.12(2), it suffices to show that the fiber at \([t^\nu]\) of \( \Psi \left( C_{\nu, \mu} \right) \) is isomorphic to \( V_\mu \{ -\langle \nu-\omega_n, \mu \rangle \} \text{dim} \text{Gr}^d_n ) / 2 \} \) as a representation of \( \text{Stab}_{GL_n(\mathcal{O}) \times \mathbb{C}^\times} [t^\nu] \), disregarding cohomological degree shift. By construction, we observe that the restriction of \( \rho \) to the Levi subgroup \( \text{Stab}^\text{red}_{GL_n(\mathcal{O})} [t^\nu] \times \mathbb{C}^\times \subset \text{Stab}_{GL_n(\mathcal{O}) \times \mathbb{C}^\times} [t^\nu] \) is given by \( (g, a) \mapsto (\rho_1(ga^{2\nu-\omega_n}) \phi_\nu(a), a) \). Therefore the fiber at \([t^\nu]\) of \( \psi^* \left( C_{\nu, \mu} \right) \) is isomorphic to the pull-back of the representation \( V_\mu \{ \text{codim} \omega_n / 2 \} \) along the group homomorphism \( \text{Stab}^\text{red}_{GL_n(\mathcal{O})} [t^\nu] \times \mathbb{C}^\times \rightarrow \text{Stab}^\text{red}_{GL_d(\mathbb{C})} (J_\nu) \times \mathbb{C}^\times \) given by \( (g, a) \mapsto (\rho_1(ga^{2\nu-\omega_n}), a) \). After the \( \mathbb{C}^\times \)-equivariant twist \( \{-d(n-1)/2\} \), we obtain the desired representation. \( \square \)

\(^1\)see §5 for a correction of this claim.
Lemma 4.15. Let \( \lambda = (\ell_1, \ldots, \ell_d) \in X = \mathbb{Z}^d \) be a weight of \( GL_d(\mathbb{C}) \). Then we have an isomorphism

\[
\Psi(\mathcal{A}(\lambda)\{-\langle \omega_d, \lambda \rangle \}) \cong \mathcal{P}_{1, \ell_1} \ast \mathcal{P}_{1, \ell_2} \ast \cdots \ast \mathcal{P}_{1, \ell_d},
\]

where \( \omega_d := (1, \ldots, 1) \in \mathbb{Z}^d \) and hence \( \langle \omega_d, \lambda \rangle = \ell_1 + \cdots + \ell_d \).

Proof. Let \( \widetilde{\text{Gr}}_n^d \) be the variety of flags of \( \mathcal{O} \)-lattices \( L_{\bullet} = (L_d \subset \cdots \subset L_1 \subset L_0) \) satisfying \( \dim L_{i-1}/L_i = 1 \) for \( 1 \leq i \leq d \). This is nothing but the convolution variety \( \text{Gr}_n^1 \times \cdots \times \text{Gr}_n^1 \) (\( d \) factors). The multiplication morphism \( \overline{m}: \widetilde{\text{Gr}}_n^d \to \text{Gr}_n^d \) is given simply by \( L_{\bullet} = (L_d \subset \cdots \subset L_1 \subset L_0) \mapsto (L_d \subset L_0) \). Then we have

\[
\mathcal{P}_{1, \ell_1} \ast \mathcal{P}_{1, \ell_2} \ast \cdots \ast \mathcal{P}_{1, \ell_d} = \overline{m} (\bigotimes_{k=1}^{d} (L_{k-1}/L_k)^{\otimes \ell_k}) \langle d(n-1)/2 \{ -\langle \omega_d, \lambda \rangle \},
\]

where we denote by \( L_{i-1}/L_i \) the line bundle on \( \widetilde{\text{Gr}}_n^d \) whose fiber at \( L_{\bullet} \) is equal to \( L_{i-1}/L_i \) by an abuse of notation.

On the other hand, we put \( \widetilde{\mathcal{N}}_n^d := \mathcal{S}^{-1}(\mathcal{N}_n^d) \), which is an open subvariety of the cotangent bundle \( T^* \mathcal{B}_d \). We identify the variety \( \widetilde{\mathcal{N}}_n^d \) with the variety of pairs \( (V_{\bullet}, x) \) consisting of a complete flag \( V_{\bullet} = \{0\} = V_d \subset \cdots \subset V_1 \subset V_0 = \mathbb{C}^d \) and a nilpotent endomorphism \( x \in \mathcal{N}_n^d \) satisfying \( x(V_{i-1}) \subset V_i \) for all \( 1 \leq i \leq d \). Then we have

\[
\pi^* \mathcal{O}_\mathcal{B}_d(\lambda)|_{\widetilde{\mathcal{N}}_n^d} = \bigotimes_{k=1}^{d} (V_{k-1}/V_k)^{\otimes \ell_k},
\]

where we denote by \( V_{i-1}/V_i \) the line bundle on \( \widetilde{\mathcal{N}}_n^d \) whose fiber at \( (V_{\bullet}, x) \) is equal to \( V_{i-1}/V_i \) by an abuse of notation.

Let \( \widetilde{\mathcal{M}}_n^d \) be the variety of pairs \( (L_{\bullet}, \gamma) \) such that:

(i) \( L_{\bullet} = (L_d \subset \cdots \subset L_1 \subset L_0) \) is a flag of \( \mathcal{O} \)-lattices with \( \dim L_{i-1}/L_i = 1 \) for \( 1 \leq i \leq d \);

(ii) \( \gamma \) is a \( \mathbb{C} \)-linear isomorphism \( \mathbb{C}^d \xrightarrow{\sim} L_0/L_d \).

This space \( \widetilde{\mathcal{M}}_n^d \) fits into the following commutative diagram

\[
(4.3)
\]

where the morphism \( \tilde{\psi}_1 \) is the projection \( (L_{\bullet}, \gamma) \mapsto L_{\bullet} \) and the morphism \( \tilde{\psi}_2 \) is given by

\[
(L_{\bullet}, \gamma) \mapsto (\{0\} \subset \mathcal{N}_n^d \subset \cdots \subset \gamma^{-1}(L_1/L_d) \subset \mathbb{C}^d, \gamma^{-1} \circ t|_{L_0/L_d} \circ \gamma).
\]

All arrows in the diagram (4.3) are \( GL_d(\mathbb{C}) \times GL_n(\mathcal{O}) \times \mathbb{C}^\times \)-equivariant. Moreover, both the left and the right squares are Cartesian. The morphism \( \tilde{\psi}_1 \) is a principal \( GL_d(\mathbb{C}) \)-bundle.

Since there is a \( GL_d(\mathbb{C}) \times GL_n(\mathcal{O}) \times \mathbb{C}^\times \)-equivariant isomorphism of line bundles

\[
\gamma: \tilde{\psi}_2 \left( \bigotimes_{k=1}^{d} (V_{k-1}/V_k)^{\otimes \ell_k} \right) \xrightarrow{\sim} \tilde{\psi}_1 \left( \bigotimes_{k=1}^{d} (L_{k-1}/L_k)^{\otimes \ell_k} \right),
\]
we have
\[
\psi^* P_* \left( \bigotimes_{k=1}^d (V_{k-1}/V_k) \otimes e_k \right) \cong (\psi_1^* )^{-1} m_* \psi_2^* \left( \bigotimes_{k=1}^d (V_{k-1}/V_k) \otimes e_k \right)
\]
\[
\cong m_* (\psi_1^* )^{-1} \psi_2^* \left( \bigotimes_{k=1}^d (V_{k-1}/V_k) \otimes e_k \right)
\]
\[
\cong m_* \left( \bigotimes_{k=1}^d (L_{k-1}/L_k) \otimes e_k \right),
\]
where we applied the smooth base change formula (cf. [CG97, Proposition 5.3.15]) to the two Cartesian squares in the diagram (4.3). After the shift and twist where we applied the smooth base change formula (cf. [CG97, Proposition 5.3.15])

**Proof.**

We fix an element \( \beta = d_0 a_0 + d_1 a_1 \in \mathbb{Q}^+ \) (of the root system of type \( A_1^{(1)} \)) such that \( d_0 - d_1 = d \). For each \( a = (a_1, \ldots, a_{2n}) \in K \), we define an object \( \mathcal{E}(a) \in P^{GL_n(\mathbb{C}) \times C^\times} (\text{Gr}_d) \) as the following convolution product:

\[
\mathcal{E}(a) := (\mathcal{P}_{1,n})^{a_1} \ast \cdots \ast (\mathcal{P}_{k,n+1-k})^{a_k} \ast \cdots \ast (\mathcal{P}_{1,1-n})^{a_{2n}} \{ -\sum_{k < \ell} a_k a_\ell \}. 
\]

Then we have \( \Phi(\mathcal{E}(a)) = [\mathcal{E}(a)] \) (see (2.2) and (3.1)).

To each \( a \in K \), we attach the unique dominant weight \( \lambda_a \in X_+ \) which contains the integer \( n + 1 - k \) with multiplicity \( a_k \) for each \( 1 \leq k \leq 2n \).

**Corollary 4.16.** For each \( a \in K \), we have

\[
\Psi(\nabla_{\lambda_a} \{ -\langle \omega_d, \lambda_a \rangle \}) \cong \mathcal{E}(a).
\]

**Proof.** This is a consequence of Lemma 4.15 and the fact \( \delta_{\lambda_a} = \sum_{k < \ell} a_k a_\ell \), which follows from (4.1).

Let \( \omega \) denote an automorphism of the group \( GL_d(\mathbb{C}) \times C^\times \) given by \( (h, a) \mapsto (ha^2, a) \). Since \( N_d^d = (N_d^d)^\omega \), the operation \( \mathcal{F} \mapsto \mathcal{F}_\omega \) defines an auto-equivalence of \( D^{GL_d(\mathbb{C}) \times C^\times} (N_d^d) \). Then we have

\[
C_{\nu, \mu} = C_{\nu, \mu} \{ -\langle \omega_n, \mu \rangle \}, \quad \nabla_{\lambda} = \nabla_{\lambda} \{ -\langle \omega_d, \lambda \rangle \}
\]

for \( (\nu, \mu) \in D_{n,d} \) and \( \lambda \in X_+ \) respectively. Thus, Lemma 4.14 and Corollary 4.16 are rewritten as:

\[
\Psi(\nabla_{\lambda}) \cong \mathcal{E}(a),
\]

for any \( (\nu, \mu) \in D_{n,d} \) and \( a \in K(\beta) \) respectively.

**Corollary 4.17.** For any \( \xi \in K^{GL_d(\mathbb{C}) \times C^\times} (N_d^d) \), we have

\[
\iota(\Psi)(\xi) = [\Psi_(\xi^\omega^{-2}).
\]

In particular, \( [\Psi_(\xi) \) is fixed by \( \iota \) if and only if \( \xi^\omega^{-1} \) is fixed by \( \iota \).

**Proof.** It is enough to consider the case \( \xi = [C_{\nu, \mu}] \) for some \( (\nu, \mu) \in D_{n,d} \). In this case, the assertion is obvious from (4.4).

The following assertion implies Theorem 4.2.
Theorem 4.18. For each \( a \in KP_n(\beta) \), we have \( LV(\lambda_a) \in D_{n,d} \) and
\[
\Phi(\overline{B}(a)) = [\mathcal{P}_{LV(\lambda_a)}],
\]
where \( LV \) is the Lusztig-Vogan bijection (see Theorem 4.5).

**Proof.** Let \( \mathcal{L} := \bigoplus_{(\nu,\mu) \in D_{n,d}} \mathbb{Z}[q^{-1/2}][C_{\nu,\mu}] \) be a \( \mathbb{Z}[q^{-1/2}] \)-lattice of \( K^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}(N_n^d) \). Since the elements \([C_{\nu,\mu}]\) are fixed by \( \iota \) (cf. Theorem 4.5 and Theorem 4.7), we have \( \mathcal{L} \cap \iota(\mathcal{L}) = \bigoplus_{(\nu,\mu) \in D_{n,d}} \mathbb{Z}[C_{\nu,\mu}] \).

By Corollary 2.4 and (4.5), we have
\[
([\Psi]^{-1}\Phi(\overline{B}(a)))^{-1} - [\nabla_{\lambda_a}]) \in \bigoplus_{a' \in KP_n(\beta)} q^{-1}[q^{-1}][\nabla_{\lambda_a}].
\]
Combining this with Theorem 4.7, we obtain
\[
([\Psi]^{-1}\Phi(\overline{B}(a)))^{-1} - [\nabla_{\lambda_a}]_{N_n^d}] \in q^{-1/2}\mathcal{L}.
\]
By Corollary 4.17, the element \(([\Psi]^{-1}\Phi(\overline{B}(a)))^{-1}\) is \( \iota \)-invariant. Thus we have \( ([\Psi]^{-1}\Phi(\overline{B}(a)))^{-1} = [\mathcal{P}_{LV(\lambda_a)}] \).

Note that \( \mathcal{P}_{LV(\lambda_a)} \neq \mathcal{P}_{LV(\lambda)} \) if \( LV(\lambda_a) \in D_{n,d} \), and \( \mathcal{P}_{LV(\lambda_a)} = 0 \) otherwise. However the latter case can not happen because we know that \([\Psi]^{-1}\Phi(\overline{B}(a))\) is nonzero. Therefore we have \( \Phi(\overline{B}(a)) = [\Psi(C_{LV(\lambda_a)})] = [\mathcal{P}_{LV(\lambda_a)}] \).

4.4. **Comparison of the bar involutions.** In this complementary subsection, we prove the following categorical version of Corollary 4.17.

**Proposition 4.19.** For any \( \mathcal{F} \in D_{coh}^{GL_d(\mathbb{C}) \times \mathbb{C}^\times}(N_n^d) \), we have
\[
\iota \circ \Psi(\mathcal{F}) \cong \Psi \circ \iota(\mathcal{F}^{-\omega^2}).
\]

For a proof, we need to introduce some new notation.

We define an automorphism \( \sigma_1 \) of the group \( GL_d(\mathbb{C}) \times GL_n(\mathbb{O}) \times \mathbb{C}^\times \) by
\[
\sigma_1(h,g(t),a) := (\overline{h}^{-1}a^{-4}, \overline{g(t)}^{-1}, a),
\]
where \( \overline{(-)} \) denotes the transpose of matrices. We will use the same notation \( \sigma_1 \) for its restrictions to the subgroups \( GL_n(\mathbb{O}) \times \mathbb{C}^\times \) or \( GL_d(\mathbb{C}) \times \mathbb{C}^\times \). For the subgroup \( GL_n(\mathbb{O}) \times \mathbb{C}^\times \), this notation is consistent with \( \sigma_1 \) defined in Section 3.5. For the subgroup \( GL_d(\mathbb{C}) \times \mathbb{C}^\times \), we have a relation \( \sigma_1 = \sigma \circ \omega^{-2} = \omega^{-2} \circ \sigma \).

Now we consider a morphism
\[
\eta' : \mathcal{M}_{n}^{d} \to GL_n(\mathbb{K}) \times GL_n(\mathbb{O}) \times (GL_n(\mathbb{K}) \times \mathbb{C}^\times) \times (GL_n(\mathbb{O}) \times \mathbb{C}^\times) \times (\mathcal{M}_{n}^{d})^{-1} \sigma_1
\]
given by
\[
\eta'(L, \gamma) := [g(t), (\overline{g(t)}^{-1}L_0) \sim \overline{\gamma^{-1}}].
\]
Here \( g(t) \in GL_n(\mathbb{K}) \) is an element such that \( L = g(t)L_0 \), and the \( \mathbb{C} \)-linear isomorphism \( \overline{\gamma} : (t^\omega L_0^{-1}) / tL_0 \sim \mathbb{C}^d \) is determined so that the following diagram commutes
\[
\begin{array}{ccc}
(L_0 / g(t)L_0)^* & \xrightarrow{\gamma^*} & (\mathbb{C}^d)^* \\
\downarrow \cong & & \downarrow \cong \\
(t^\omega g(t)^{-1}L_0) / tL_0 & \xrightarrow{\overline{\gamma}} & \mathbb{C}^d,
\end{array}
\]
where the isomorphism \((L_0/g(t)L_0)^* \xrightarrow{2\pi} (t^*g(t)^{-1}L_0)/tL_0\) is given by the residue pairing
\[
\langle -, - \rangle : \mathcal{K}^n \times \mathcal{K}^n \to \mathbb{C}; \quad \langle v(t), w(t) \rangle := \text{Res}_{t=0} \frac{T_v(t) \cdot w(t)}{t} dt,
\]
and the isomorphism \((\mathbb{C}^d)^* \xrightarrow{\sim} \mathbb{C}^d\) is given by the standard pairing \(\langle v, w \rangle := T_v \cdot w.\) We can easily check that the resulting coset \([g(t), (T_g(t)L_0, (T_g(t)^{-1} \circ T_\gamma)^{-1})]\) is independent of the choice of \(g(t) \in GL_n(\mathbb{K})\) such that \(L = g(t)L_0.\)

**Lemma 4.20.** The morphism \(\eta'\) is \(GL_d(\mathbb{C}) \times GL_n(\mathcal{O}) \rtimes \mathbb{C}^\times\)-equivariant.

**Proof.** This is proved by the following straightforward computation. For \((g(t)L_0, \gamma) \in \mathcal{M}_n^d\) and \((h, g_1(t), a) \in GL_d(\mathbb{C}) \times GL_n(\mathcal{O}) \rtimes \mathbb{C}^\times\), we compute:
\[
\eta'((h, g_1(t), a) \cdot (g(t)L_0, \gamma)) = \eta'(g_1(t)g(a^4t)L_0, (g_1(t), a) \circ \gamma \circ h^{-1})
\]
\[
= [g_1(t)g(a^4t), (T_{g_1(t)}g(a^4t)L_0, (T_{g_1(t)}g(a^4t)^{-1}) \circ (T_{g_1(t)}, a) \circ \gamma \circ h^{-1}^{-1})]
\]
\[
= [g_1(t)g(a^4t), (T_{g_1(t)}g(a^4t)L_0, (T_{g_1(t)}g(a^4t)^{-1}) \circ (T_{g_1(t)}, a) \circ \gamma \circ h^{-1}^{-1})]
\]
\[
= (h, g_1(t), a) \cdot (g(t), (T_g(t)L_0, (T_g(t)^{-1} \circ T_\gamma)^{-1})).
\]
Therefore we have \(\eta'((h, g_1(t), a) \cdot (g(t)L_0, \gamma)) = (h, g_1(t), a) \cdot \eta'(g(t)L_0, \gamma).\) \(\square\)

Let \(\psi_2 : GL_n(\mathcal{K}) \times GL_n(\mathcal{O}) (\mathcal{M}_n^d)^{\sigma_1} \to (\mathcal{N}_n^d)^{\sigma_1}\) be a morphism defined by the assignment \([g(t), (L, \gamma)] \mapsto \gamma^{-1} \circ t|_{L_0/L} \circ \gamma.\) We can easily check that this is well-defined and \(GL_d(\mathbb{C}) \times GL_n(\mathcal{O}) \rtimes \mathbb{C}^\times\)-equivariant. On the other hand, the transpose map \(x \mapsto T_x\) induces a \(GL_d(\mathbb{C}) \times \mathbb{C}^\times\)-equivariant morphism \(\tau : \mathcal{N}_n^d \to (\mathcal{N}_n^d)^{\sigma_1}.\)

**Lemma 4.21.** The following diagram commutes:

\[
\begin{array}{ccc}
\mathcal{G}_n^d & \xrightarrow{\psi_1} & \mathcal{M}_n^d & \xrightarrow{\psi_2} & \mathcal{N}_n^d \\
\| & \downarrow{g} \quad & \downarrow{\eta'} \quad & \downarrow{\tau} \\
GL_n(\mathcal{K}) \times GL_n(\mathcal{O}) (\mathcal{G}_n^d)^{\sigma_1} & \xrightarrow{(\text{id} \times \psi_1)} & GL_n(\mathcal{K}) \times GL_n(\mathcal{O}) (\mathcal{M}_n^d)^{\sigma_1} & \xrightarrow{\psi_2} & (\mathcal{N}_n^d)^{\sigma_1},
\end{array}
\]

where all arrows are \(GL_d(\mathbb{C}) \times GL_n(\mathcal{O}) \rtimes \mathbb{C}^\times\)-equivariant.

**Proof.** The commutativity of the left square is obvious from the definitions. The commutativity of the right square follows from the relation
\[
T(\gamma^{-1} \circ t|_{L_0/g(t)L_0} \circ \gamma) = T_\gamma \circ t|_{L_0/g(t)L_0} \circ T_\gamma^{-1},
\]
which holds for any \((g(t)L_0, \gamma) \in \mathcal{M}_n^d.\) \(\square\)
Proof of Proposition 4.19. Using the commutative diagram (4.6), we have
\[
\eta^* (\mathcal{O}_{\text{Gr}^d_n} \boxtimes \psi^* (\mathcal{F})^{\sigma_1}) \cong (\psi'_1)^{-1}(\eta')^* (\mathcal{O}_{\text{Gr}'_n^d} \boxtimes \psi'^*_2 (\mathcal{F}^{\sigma_1})) \\
= (\psi'_1)^{-1}(\eta')^* (\psi'_2)^* \mathcal{F}^{\sigma_1} \\
= (\psi'_1)^{-1} \psi'^*_2 \tau^*(\mathcal{F}^{\omega^{-2}})^\sigma \\
\cong \psi'^* \tau^*(\mathcal{F}^{\omega^{-2}})^\sigma,
\]
and hence \( \eta^* (\mathcal{O}_{\text{Gr}^d_n} \boxtimes \Psi(\mathcal{F})^{\sigma_1}) \cong \Psi \circ \tau^*(\mathcal{F}^{\omega^{-2}})^\sigma \). Applying the duality functor \( \mathbb{D}_{\text{Gr}^d_n} \), we have
\[
\iota \circ \Psi(\mathcal{F}) = \mathbb{D}_{\text{Gr}^d_n} \circ \eta^* (\mathcal{O}_{\text{Gr}^d_n} \boxtimes \Psi(\mathcal{F})^{\sigma_1}) \cong \Psi \circ \mathbb{D}_{\text{Gr}'_n^d} \circ \tau^*(\mathcal{F}^{\omega^{-2}})^\sigma = \Psi \circ \iota(\mathcal{F}^{\omega^{-2}}),
\]
where we used Proposition 4.12(3) and the relation (4.2). \( \square \)

5. Erratum

We are grateful to Vasily Krylov and Sabin Cautis who have noticed that Lemma 4.14 is false as stated. Namely, the map
\[
\Psi : K^{GL_d(\mathbb{C}) \times \mathbb{C}^*}(\text{N}^d_n) \to K^{GL_n(\mathcal{O}) \times \mathbb{C}^*}(\text{Gr}^d_n)
\]
is not an isomorphism, it is only injective. Indeed, certain parts of \( \nu = (\nu_1 \geq \ldots \geq \nu_n \geq 0) \) can be zero, so we write \( \nu = (i^\nu) \), \( \sum_{i \geq 0} n_i = n \), allowing \( i = 0 \). Then the reductive part of the stabilizer in \( GL(d) \) is \( \prod_{i \geq 1} GL(n_i) \), while the reductive part of the stabilizer in \( GL(n, \mathcal{O}) \) is \( \prod_{i \geq 0} GL(n_i) \). Hence \( [\Psi] \) is not surjective in general, when \( n_0 > 0 \).

When Lemma 4.14 is used in the proof of the main Theorem 4.1, we actually do not use the surjectivity of \( [\Psi] \), but the following weaker statement. Given \( \mathcal{P}_{\nu, \mu} \in K^{GL_n(\mathcal{O}) \times \mathbb{C}^*}(\text{Gr}^d_n) \), there is a positive integer \( N \gg 0 \) such that the convolution \( \mathcal{P}_{\nu, \mu} \ast \mathcal{P}_{\nu', \mu'} \) lies in the image of \( [\Psi] \), where \( \mu' = (0, \ldots, 0) \), \( \nu' = (N, \ldots, N) \). This weaker statement clearly holds true.
