CYCLOTOMY OF WEIL SUMS OF BINOMIALS

YVES AUBRY, DANIEL J. KATZ, AND PHILIPPE LANGEVIN

Abstract. The Weil sum $W_{K,d}(a) = \sum_{x \in K} \psi(x^d + ax)$ where $K$ is a finite field, $\psi$ is an additive character of $K$, $d$ is coprime to $|K^\times|$, and $a \in K^\times$ arises often in number-theoretic calculations, and in applications to finite geometry, cryptography, digital sequence design, and coding theory. Researchers are especially interested in the case where $W_{K,d}(a)$ assumes three distinct values as $a$ runs through $K^\times$. A Galois-theoretic approach is used here to prove a variety of new results that constrain which fields $K$ and exponents $d$ support three-valued Weil sums, and restrict the values that such Weil sums may assume.

1. Introduction

Let $K$ be a finite field of characteristic $p$. Let $\psi_K$ be the canonical additive character of $K$, that is, $\psi_K(x) = \exp(2i\pi \text{Tr}_{K/F_p}(x)/p)$ where $\text{Tr}_{K/F_p}$ is the absolute trace. Weil sums with $\psi_K$ applied to binomials, that is, sums of the form $\sum_{x \in K} \psi_K(bx^j + cx^k)$, have been studied extensively from the early twentieth century to present [31, 36, 40, 14, 1, 24, 6, 7, 32, 30, 11, 9, 10]. We are interested in such sums when $j$ and $k$ are coprime to $|K^\times|$, in which case we reparameterize them to obtain sums of the form

$$W_{K,d}(a) = \sum_{x \in K} \psi_K(x^d + ax)$$

with $\gcd(d,|K^\times|) = 1$ and $a \in K$. This definition will remain in force throughout the paper, and we shall always insist that $\gcd(d,|K^\times|) = 1$ whenever we write $W_{K,d}$. The sums $W_{K,d}(a)$ are always real algebraic integers [21, Theorem 3.1(a)], and furthermore, are all rational integers if and only if $d \equiv 1 \pmod{p - 1}$ [21, Theorem 4.2]. Apart from arising often in number-theoretic calculations, these sums are also the key to problems in finite geometry, cryptography, digital sequence design, and coding theory, as discussed in [28, Appendix].

For a fixed $K$ and $d$, we consider $W_{K,d}(a)$ as a function of $a \in K^\times$, and are interested in how many different values it assumes as $a$ runs through $K^\times$. $W_{K,d}(a)$ with $a = 0$ is passed over, as it is the Weil sum of the monomial $x^d$, and since $x \mapsto x^d$ is a permutation of $K$, we always have $W_{K,d}(0) = 0$. We call $\{W_{K,d}(a) : a \in K^\times\}$ the value set of $W_{K,d}$, and say that $W_{K,d}$ is $v$-valued over $K$ to mean that this set is of cardinality $v$.

Date: first version: 12 December 2013; this version: 05 December 2014.
If \( d \equiv p^j \pmod{|K^\times|} \) for some \( j \), we say that \( d \) is degenerate over \( K \), because \( \text{Tr}_{K/F}(x^d + ax) = \text{Tr}_{K/F}((1 + a)x) \), and so the binomial effectively becomes zero (if \( a = -1 \)) or a nonvanishing linear form (if \( a \neq -1 \)). Thus if \( d \) is degenerate over \( K \), then readily obtains for \( a \in K \) that

\[
W_{K,d}(a) = \begin{cases}
|K| & \text{if } a = -1, \\
0 & \text{otherwise}.
\end{cases}
\]

Helleseth [21, Theorem 4.1] shows that one always obtains a richer value set in the nondegenerate case.

**Theorem 1.1** (Helleseth, 1976). If \( d \) is nondegenerate over \( K \), then \( W_{K,d}(a) \) takes at least three values as \( a \) runs through \( K \times \).

Here we want to know when Weil sums of this form can be three-valued, and if so, what are the three values they may take. We indicate all known infinite families of three-valued examples, arranged according to analogy, in Table 1 below.

| order of \( K \) | \( d \) (nondegenerate) | values of \( W_{K,d} \) | reference |
|-----------------|------------------------|----------------------|----------|
| \( q = 2^e \)   | \( d = 2^i + 1 \) \<br>\( \text{val}_2(i) \geq \text{val}_2(e) \) | \( 0, \pm \sqrt{2^{\gcd(e,i)}q} \) | \[25, 27, 19\] |
| \( q = p^e \)   | \( d = \frac{1}{2} (p^{2i} + 1) \) \<br>\( \text{val}_2(i) \geq \text{val}_2(e) \) | \( 0, \pm \sqrt{p^{\gcd(e,i)}q} \) | \[39\] (e odd) |
| \( q = 2^e \)   | \( d = 2^{2i} - 2^i + 1 \) \<br>\( \text{val}_2(i) \geq \text{val}_2(e) \) | \( 0, \pm \sqrt{2^{\gcd(e,i)}q} \) | \[41, 26\] |
| \( q = p^e \)   | \( d = p^{2i} - p^i + 1 \) \<br>\( \text{val}_2(i) \geq \text{val}_2(e) \) | \( 0, \pm \sqrt{p^{\gcd(e,i)}q} \) | \[39\] (e odd) |
| \( q = 2^e \)   | \( \text{val}_2(e) = 1 \) \<br>\( d = 2^{e/2} + 2^{(e+2)/4} + 1 \) | \( 0, \pm 2\sqrt{q} \) | \[12\] |
| \( q = 2^e \)   | \( \text{val}_2(e) = 1 \) \<br>\( d = 2^{(e+2)/4} + 3 \) | \( 0, \pm 2\sqrt{q} \) | \[12\] |
| \( q = 2^e \)   | \( e \) odd \<br>\( d = 2^{(e-1)/2} + 3 \) | \( 0, \pm \sqrt{2q} \) | \[4, 5, 22\] |
| \( q = 3^e \)   | \( e \) odd \<br>\( d = 2 \cdot 3^{(e-1)/2} + 1 \) | \( 0, \pm \sqrt{3q} \) | \[16\] |
| \( q = 2^e \)   | \( e \) odd \<br>\( d = 2^{2i} + 2^i - 1 \) \<br>\( e \mid 4i + 1 \) | \( 0, \pm \sqrt{2q} \) | \[22, 23\] |
| \( q = 3^e \)   | \( e \) odd \<br>\( d = 2 \cdot 3^i + 1 \) \<br>\( e \mid 4i + 1 \) | \( 0, \pm \sqrt{3q} \) | \[29\] |
| \( q = 3^e \)   | \( e \) odd \<br>\( d = \frac{3^{i+1} - 1}{3^i + 1} + \frac{3^{e-1}}{2} \) \<br>\( 2i \mid e + 1 \) | \( 0, \pm \sqrt{3q} \) | \[15\] |
In several entries, we make use of the \textit{p-adic valuation} of an integer \(a\), denoted \(\text{val}_p(a)\), which is the maximum \(k\) such that \(p^k \mid a\) (or \(\infty\) if \(a = 0\)). We tacitly impose the condition that \(d\) be nondegenerate over \(K\) throughout the table, so that, for example, we cannot have \(i = 0\) in the first four rows. If \(K\) has characteristic \(p\) and \(1/d\) is interpreted modulo \(|K^\times|\), then \(W_{K,pd}\) and \(W_{K,1/d}\) take the same values as \(W_{K,d}\) \cite[Theorem 3.1]{21}, so the table records representative \(d\) modulo these equivalences.

First of all, note that all these value sets consist of three rational integers, one of which is 0, with the other two being opposites of each other. The first two properties are inevitable facts, as shown in \cite[Theorems 1.7, 1.9]{28}.

**Theorem 1.2** (Katz, 2012). Let \(K\) be a finite field of characteristic \(p\). If \(W_{K,d}\) is three-valued for some exponent \(d\), then \(d \equiv 1 \pmod{p - 1}\), and the values must be rational integers, one of which is zero.

Concerning the two nonzero values of a three-valued Weil sum, one must be positive and the other negative, since it is known that \(\sum_{a \in K^\times} W_{K,d}(a)^2 = (\sum_{a \in K^\times} W_{K,d}(a))^2\). (See Lemma \[2.1\] and Corollary \[2.3\] below for details.) However, it has not been proved that these values must have the same magnitude, although this is always what has been observed. We say that a three-valued Weil \(W_{K,d}\) sum is \textit{symmetric} when the two nonzero values are opposites of each other. If we assume that a three-valued Weil sum is symmetric, we can make further conclusions about the possible values.

**Proposition 1.3.** If \(K\) is the finite field of characteristic \(p\) and order \(q\), and if \(W_{K,d}(a)\) is three-valued with values 0 and \(\pm A\), then \(|A| = p^k\) for some positive integer \(k\) with \(\sqrt{q} < p^k < q\).

This follows easily from well-known facts, which are arranged in Section \[2\] where the above proposition is proved as Proposition \[2.4\].

Our first main result shows that in many cases, \(W_{K,d}\) cannot be symmetric three-valued.

**Theorem 1.4.** Let \(K\) be a finite field, and suppose that \(I\) and \(J\) are subfields of \(K\) with \([J : I] = 2\), with \(d\) degenerate over \(I\) but not over \(J\). Then the set of values assumed by \(W_{K,d}(a)\) as \(a\) runs through \(K^\times\) is not of the form \([-A, 0, +A]\) for any \(A\).

We prove this in Section \[6\]. This means that a field obtained by a tower of quadratic extensions over a prime field can never support a three-valued sum.

**Corollary 1.5.** Let \(K\) be a finite field of characteristic \(p\), and suppose that \([K : \mathbb{F}_p]\) is a power of 2. Then the set of values assumed by \(W_{K,d}(a)\) as \(a\) runs through \(K^\times\) is not of the form \([-A, 0, +A]\) for any \(A\).

For if \(W_{K,d}\) were three-valued, Theorem \[1.2\] and eq. \[2\] would make \(d\) degenerate over \(\mathbb{F}_p\), but not over \(K\), and then as we proceed from \(\mathbb{F}_p\) toward \(K\) up the tower of quadratic extensions, we must find a step where \(d\) passes
from degenerate to nondegenerate. This corollary generalizes a result of 
Calderbank-McGuire-Poonen-Rubinstein [3, Theorem 3]. Our proof is quite 
different from that of Calderbank et al., who used McEliece’s Theorem from 
coding theory (a relative of Stickelberger’s Theorem on the \(p\)-divisibility of 
Gauss sums) and a delicate calculation in additive number theory to obtain 
Corollary 1.5 in the case where \(p = 2\). The proof for Theorem 1.4 in full 
generality given here is much more straightforward, and is the consequence 
of some useful observations about the \(p\)-adic valuation of Weil sums.

Helleseth conjectured [21, Conjecture 5.2] that the hypotheses of Corollary 
1.5 make it impossible for the Weil sum to be three-valued at all.

**Conjecture 1.6** (Helleseth, 1976). Let \(K\) be a finite field of characteristic 
\(p\). If \([K : \mathbb{F}_p]\) is a power of 2, then \(W_{K,d}\) is not three-valued.

If it were proved that three-valued Weil sums must be symmetric, this 
would follow from Corollary 1.5. The \(p = 2\) case of Conjecture 1.6 has 
been proved. First, Feng [17, Theorem 2] showed that if \(p = 2\), one could 
strengthen the conclusion of Corollary 1.5 to say that the value set is not 
only non-symmetric, but entirely lacks the value 0. Then when Katz [28, 
Theorem 1.9] proved that a three-valued Weil sum must take the value 0, 
Conjecture 1.6 was established for \(p = 2\).

A symmetric three-valued Weil sum is called *preferred* if the magnitude 
of the nonzero values is as small as possible in view of Proposition 1.3, that 
is, if the nonzero values are \(\pm \sqrt{pq}\) when \(q\) is an odd power of \(p\), or if the 
nonzero values are \(\pm p\sqrt{q}\) when \(q\) is an even power of \(p\). This terminology 
originates from digital sequence design, wherein smaller magnitude Weil 
sums of binomials correspond to smaller cross-correlation between a pair of 
maximal linear recursive sequences, which is desirable. The known infinite 
families of preferred three-valued Weil sums can be deduced from Table 1 
above: the last five rows furnish preferred Weil sums, and in the first four 
rows, one must have \(\gcd(e, i) = 1\) if \(e\) is odd, or \(\gcd(e, i) = 2\) if \(e\) is even.

Our second main result is a lower bound on the magnitude of the nonzero 
values of a symmetric three-valued Weil sum \(W_{K,d}\). This bound grows as 
the 2-divisibility of the degree of \(K\) over its prime field increases.

**Theorem 1.7.** Let \(K\) be the finite field of characteristic \(p\) and order \(q\). If 
\(\text{val}_2([K : \mathbb{F}_p]) = s\) and \(W_{K,d}\) is symmetric three-valued with values \(0, \pm A\), 
then \(|A| \geq p^{2s-1} \sqrt{q}\).

We prove this in Section 7. One consequence is that if the degree of \(K\) 
over its prime field is a multiple of 4, then \(W_{K,d}\) cannot be preferred.

**Corollary 1.8.** Let \(K\) be the finite field of characteristic \(p\) and order \(q\). If 
\([K : \mathbb{F}_p] \equiv 0 \pmod{4}\), then the set of values assumed by \(W_{K,d}\) as \(a\) runs 
through \(K^\times\) is not of the form \(\{0, \pm p\sqrt{q}\}\).

This generalizes the result of Calderbank-McGuire [2], who proved a con-
jecture of Sarwate and Pursley [38, p. 603], which is the special case of
Corollary 1.8 where \( p = 2 \). Our proof technique for Theorem 1.7 in full
generality is much simpler than the original proof of Calderbank-McGuire,
as it obviates the need for McEliece’s Theorem or Stickelberger’s Theorem.

Our first two results give restrictions on the types of fields that support
symmetric and preferred Weil sums. Our third result shows that certain
exponents \( d \) of the polynomial in the Weil sum prevent the Weil sum from
being three-valued at all.

**Theorem 1.9.** Let \( K \) be a finite field of characteristic \( p \) with \([K : \mathbb{F}_p] \) even. If \( d \) is a power of \( p \) modulo \( \sqrt{|K| - 1} \), then \( W_{K,d} \) is not three-valued.

In other words, it is impossible for \( W_{K,d} \) to be three-valued if \( K \) is the
quadratic extension of a field \( F \) in which \( d \) is degenerate. We prove this in
Section 8. Such an exponent \( d \) is called a *Niho exponent*, since they were
first studied by Niho in [37]. Theorem 1.9 generalizes the result of Charpin
[8, Theorem 2], who proved the \( p = 2 \) case. Some steps of Charpin’s proof
for characteristic two do not hold in odd characteristic, so new arguments
are devised.

Finally, the techniques developed here can be used to simplify the proof
that the values of a three-valued Weil sum must be rational integers, a result
that appears above in Theorem 1.2 and which originally appeared in [28,
Theorem 1.7].

Our proofs of all the above results make extensive use of Galois theory.
Since Weil sums connect calculations in finite fields to calculations in cyclo-
tomic extensions of \( \mathbb{Q} \), there are two realms, both cyclotomic, where Galois
groups come into play. On the one hand, there are Galois groups for finite
fields, which act on the terms of the polynomial arguments of the characters
in the Weil sums; this is explored in Section 3. On the other hand, there are
Galois groups for cyclotomic fields, which are applied to the values of the
Weil sums; this is explored in Section 5. This dual Galois-theoretic approach
has proved to be both powerful for obtaining new results, and at the same
time, simplifies the proofs of previous results that we recapitulate.

The organization of this paper is as follows: in Section 2, we prove some
preliminary results using the well-known methodology of power moments.
In Section 3 we explore the action of the Galois groups of finite fields on the
terms inside the Weil sums. In Section 4 we look at the Fourier transform of
the value set of our Weil sums, which is expressible in terms of Gauss sums,
from which we deduce results about the \( p \)-adic valuation of Weil sum values.
In Section 5 we explore the action of the Galois groups of cyclotomic fields
on the values of the Weil sums. In Sections 6, 7, and 8 we prove Theorems
1.4, 1.7, and 1.9 respectively. In the Appendix, we finish with our new
simpler proof of the rationality of the values of three-valued Weil sums.

## 2. Power Moments of Weil Sums

In this section we state some of the basic results about Weil sums that will
be useful later on. These facts are proved using character sums known as
power moments. Recall the definition \((11)\) of \(W_{K,d}\), and our tacit insistence that gcd\((d, |K^\times|) = 1\) whenever we write \(W_{K,d}\). The \(n\)th power moment of the Weil sum \(W_{K,d}\) is the sum

\[
\sum_{a \in K^\times} W_{K,d}(a)^n.
\]

The first few power moments can be calculated as straightforward character sums.

**Lemma 2.1.** Let \(K\) be a finite field. Then

(i). \(\sum_{a \in K^\times} W_{K,d}(a) = |K|\),

(ii). \(\sum_{a \in K^\times} W_{K,d}(a)^2 = |K|^2\), and

(iii). \(\sum_{a \in K^\times} W_{K,d}(a)^3 = |K|^2 \cdot |R|\),

where \(R\) is the set of roots of the polynomial \((x + 1)^d - x^d - 1\) in \(K\).

**Proof.** See [28, Proposition 3.1].

**Corollary 2.2.** If \(K\) is a finite field, and \(d\) is nondegenerate over \(K\), then \(|W_{K,d}(a)| < |K|\) for all \(a \in K^\times\).

**Proof.** From Lemma 2.1(iii), the only way to escape this conclusion would be to have \(|W_{K,d}(b)| = |K|\) for some \(b \in K^\times\), and \(W_{K,d}(a) = 0\) for all other \(a\), which would make the Weil sum two-valued, contrary to Theorem 1.1.

**Corollary 2.3.** If \(d\) is nondegenerate over \(K\), then \(W_{K,d}\) assumes at least one positive value and at least one negative value.

**Proof.** Recall that the Weil sum values are real algebraic integers [21, Theorem 3.1(a)]. By Theorem 1.1 we know that \(W_{K,d}\) must assume at least two nonzero values. If all the nonzero values it assumes were of the same sign, then \((\sum_{a \in K^\times} W_{K,d}(a))^2 > \sum_{a \in K^\times} W_{K,d}(a)^2\), contradicting Lemma 2.1(iii) and (iii).

The following is an easy consequence of this power moment analysis, and provides the proof of Proposition 1.3 in the Introduction.

**Proposition 2.4.** If \(K\) is the finite field of characteristic \(p\) and order \(q\), and if \(W_{K,d}(a)\) is three-valued with values \(0\) and \(\pm A\), then \(d \equiv 1 \pmod{p - 1}\) and \(|A| = p^k\) for some positive integer \(k\). If \(R\) denotes the set of roots of \((x + 1)^d - x^d - 1\) in \(K\), then \(\sqrt{q} < \sqrt{|R|q} = |A| < q\).

**Proof.** By Theorem 1.2 we must have \(A \in \mathbb{Z}\) and \(d \equiv 1 \pmod{p - 1}\). Let \(N_A\) be the number of \(a \in K^\times\) with \(W_{K,d}(a) = A\). Since the other two values \(W_{K,d}(a)\) assumes \(0\) and \(-A\), we have \(\sum_{a \in K^\times} W_{K,d}(a)(W_{K,d}(a) + A) = 2A^2N_A\), and by Lemma 2.1(iii), this sum also equals \(q^2 + qA\), so that \(N_A = (q^2 + qA)/(2A^2)\), and so \(A\) can not be divisible by any prime other than \(p\). We know \(|A| < q\) by Corollary 2.2.

Similarly, \(\sum_{a \in K^\times} W_{K,d}(a)(W_{K,d}(a)^2 - A^2) = 0\), and by Lemma 2.1(iii), this equals \(q^2|R| - qA^2\), so \(|A| = \sqrt{|R|q}\). Then note that \(0, -1 \in R\). (This is
clear for \( p = 2 \), and for \( p \) odd, note that \( \gcd(d, q - 1) = 1 \) forces \( d \) to be odd.) Thus \( A \geq \sqrt{2q} \). \( \square \)

It will also be useful to consider a version of the first power moment of a Weil sum, but where we restrict the summation to a smaller subfield.

**Lemma 2.5.** Let \( K \) be a finite field and let \( L \) be the quadratic extension of \( K \). Then

\[
\sum_{a \in K^\times} W_{L, d}(a) = |L|.
\]

**Proof.** Let \( q = |K| \). Since \( W_{L, d}(0) = 0 \), we have

\[
\sum_{a \in K^\times} W_{L, d}(a) = \sum_{x \in L} \psi_L(x^d) \sum_{a \in K} \psi_K(a \Tr_{L/K}(x)) = q \sum_{x \in L} \psi_L(x^d).
\]

If \( x \in L \) with \( \Tr_{L/K}(x) = 0 \), then \( x^q = -x \), so that \( \Tr_{L/K}(x^d) = x^{qd} + x^d = (-x)^d + x^d = 0 \). (In odd characteristic, \( \gcd(d, q - 1) = 1 \) makes \( d \) odd.) Thus \( \sum_{a \in K^\times} W_{L, d}(a) = q \cdot |\{ x \in L : \Tr_{L/K}(x) = 0 \}| = q^2 = |L| \). \( \square \)

3. Action of Galois Groups of Finite Fields

We begin this section by seeing that the automorphisms of a finite field \( K \) act trivially with respect to the Weil sum \( W_{K, d}(a) \). As always \( W_{K, d}(a) \) is as defined in [1], and \( \gcd(d, |K^\times|) = 1 \) whenever we write \( W_{K, d} \).

**Lemma 3.1.** Let \( K \) be a finite field of characteristic \( p \). If \( \sigma \in \text{Gal}(K/F_p) \), then \( W_{K, d}(\sigma(a)) = W_{K, d}(a) \).

**Proof.** Since Galois conjugates have the same trace, they have the same character value. Thus \( W_{K, d}(a) = \sum_{x \in K} \psi_K(\sigma(x^d + ax)) \), and by reparameterizing with \( y = \sigma(x) \), we have \( W_{K, d}(a) = \sum_{y \in K} \psi_K(y^d + \sigma(a)y) = W_{K, d}(\sigma(a)) \). \( \square \)

The action of the Galois group also shows that some exponents give equivalent Weil sums.

**Lemma 3.2.** Let \( K \) be a finite field of characteristic \( p \). Then \( W_{K, d}(a) = W_{K, p^j d}(a) \) for any \( a \in K \) and \( j \in \mathbb{Z} \).

**Proof.** This follows immediately from the fact that \( x^{p^j d} \) is a Galois conjugate of \( x^d \), and so \( \psi_K(x^{p^j d}) = \psi_K(x^d) \). \( \square \)

Now we use finite field automorphisms to prove a congruence between the Weil sum over a field and the Weil sum over its extensions.
Lemma 3.3. Let $K$ be a finite field of characteristic $p$, and let $L$ be an extension of $K$ with $[L : K]$ a power of a prime $\ell$ distinct from $p$. Then for any $a \in K$, we have
\[
W_{L,d}(a) \equiv W_{K,d}([L : K]^{-1/d}a) \pmod{\ell},
\]
where $1/d$ indicates the multiplicative inverse of $d$ modulo $p - 1$.

Proof. For $a \in K$, we have
\[
W_{L,d}(a) = \sum_{x \in K} \psi_K(\text{Tr}_{L/K}(x^d + ax)) + \sum_{x \in L \setminus K} \psi_L(x^d + ax).
\]
The first sum equals $\sum_{x \in K} \psi_K([L : K](x^d + ax))$, and if we reparameterize with $w = [L : K]^{1/d}x$, then we see that this sum is $W_{K,d}([L : K]^{1-1/d}a)$. For the second sum, the action of $\text{Gal}(L/K)$ partitions $L \setminus K$ into orbits of Galois conjugates whose sizes are positive powers of $\ell$. For any $\sigma \in \text{Gal}(K/L)$, we have $\psi_L(x^d + ax) = \psi_L(\sigma(x^d + ax)) = \psi_L(\sigma(x)^d + a\sigma(x))$, so that the value of $\psi_L(x^d + ax)$ is constant on orbits, and thus the sum over $L \setminus K$ is $\ell$ times a sum of algebraic integers. \hfill \qed

We then explore what this tells us in the case where $d$ is degenerate in the smaller field.

Corollary 3.4. Let $K$ be a finite field of characteristic $p$, and let $L$ be an extension of $L$ with $[L : K]$ a power of a prime $\ell$ distinct from $p$. Let $d$ be degenerate over $K$. Then $W_{K,d}(-1) \equiv |K| \pmod{\ell}$ and $W_{K,d}(a) \equiv 0 \pmod{\ell}$ for every $a \in K \setminus \{-1\}$.

Proof. Combine Lemma 3.3 with (2), and note that since $d$ is degenerate over $K$, we have $d \equiv 1 \pmod{p - 1}$, so the factor of $[L : K]^{1-1/d}$ mentioned in Lemma 3.3 is equal to 1. \hfill \qed

4. Gauss Sum and Valuation

In this section, we explore the Fourier transform of the value set of the Weil sum, which is expressible in terms of Gauss sums. This will enable us to prove some criteria about the $p$-divisibility of Weil sum values.

Throughout this section $K$ is a finite field of characteristic $p$ and order $q$ and, as always, we assume that $\gcd(d, q - 1) = 1$. For any multiplicative character $\chi \in \widehat{K}^\times$, we consider the Gauss sum

\[
\tau_K(\chi) = \sum_{a \in K^\times} \chi(a)\psi_K(a).
\]

By Fourier inversion, if $a \in K^\times$, we find that
\[
\psi_K(a) = \frac{1}{q-1} \sum_{\chi \in \widehat{K}^\times} \tau_K(\chi)\bar{\chi}(a).
\]
Thus for $a \in K^\times$,

$$W_{K,d}(a) = 1 + \frac{1}{(q - 1)^2} \sum_{b \in K^\times} \sum_{\chi, \varphi \in \widehat{K}^\times} \tau_K(\chi)\tau_K(\varphi)\bar{\varphi}(b)\bar{\varphi}(ab)$$

$$= 1 + \frac{1}{q - 1} \sum_{\chi, \varphi \in \widehat{K}^\times \varphi = \chi^d} \tau_K(\chi)\tau_K(\varphi)\bar{\varphi}(a)$$

$$= \frac{q}{q - 1} + \frac{1}{q - 1} \sum_{\chi \neq 1} \tau_K(\chi)\tau_K(\chi^d)\chi^d(a).$$

If we denote by $t$ the inverse of $-d$ modulo $q - 1$, the above formula shows that $q$ and the $\tau_K(\chi)\tau_K(\chi^d)$ are the Fourier coefficients of the mapping $a \mapsto W_{K,d}(a^t)$ from $K^\times$ to $\mathbb{C}$, whence by Fourier inversion

$$\sum_{a \in K^\times} W_{K,d}(a^t)\chi(a) = \begin{cases} q & \text{if } \chi = 1, \\
\tau_K(\chi)\tau_K(\chi^d) & \text{otherwise.}
\end{cases}$$

Recall from the Introduction that for any nonzero integer $n$, the $p$-adic valuation of $n$, written $\text{val}_p(n)$, is the largest $k$ such that $p^k$ divides $n$, and we set $\text{val}_p(0) = \infty$. Then $\text{val}_p(ab) = \text{val}_p(a) + \text{val}_p(b)$ and $\text{val}_p(a + b) \geq \min\{\text{val}_p(a), \text{val}_p(b)\}$, which becomes an equality whenever $\text{val}_p(a) \neq \text{val}_p(b)$. We can extend the definition to $\mathbb{Q}$, wherein $\text{val}_p(a/b) = \text{val}_p(a) - \text{val}_p(b)$. If $\zeta_p$ and $\zeta_{q-1}$ are, respectively, primitive $p$th and $(q - 1)$th roots of unity over $\mathbb{Q}$, we can further extend $\text{val}_p$ to the field $\mathbb{Q}(\zeta_p, \zeta_{q-1})$ where the Gauss sums reside, while still retaining the relations given above concerning products and sums of elements. In this last field, elements can have fractional valuations: for instance $\text{val}_p(1 - \zeta_p) = 1/(p - 1)$.

We introduce the useful notation

$$V_{K,d} = \min_{a \in K^\times} \text{val}_p(W_{K,d}(a)).$$

It is well known [34], [35, Section 6] that Stickelberger’s congruence on Gauss sums can be used to obtain the value of $V_{K,d}$ but we do not need it to reach our goal.

**Lemma 4.1.** For $K$ a finite field of order $q$, and $d$ an integer coprime to $q - 1$, we have

$$V_{K,d} = \min_{\chi \in \widehat{K}^\times \chi \neq 1} \text{val}_p(\tau_K(\chi)\tau_K(\chi^d)).$$

**Proof.** This is immediate once we note that $\text{val}_p(\chi(a)) = 0$ for any $\chi \in \widehat{K}^\times$ and any $a \in K^\times$, because $(q - 1)\text{val}_p(\chi(a)) = \text{val}_p(\chi(a)^{q-1}) = \text{val}_p(1) = 0$. Using the relation (3), one has $V_{K,d} \geq \min_{\chi \neq 1} \text{val}_p(\tau_K(\chi)\tau_K(\chi^d))$, and the reverse inequality is obtained by using the relation (4), once we establish that $\min_{\chi \neq 1} \text{val}_p(\tau_K(\chi)\tau_K(\chi^d)) \leq \text{val}_p(q)$. This last fact follows because
\[ \tau_K(\chi) = \chi(-1)\overline{\tau_K(\chi)} \text{ and } |\tau_K(\chi)|^2 = q \text{ for any nontrivial multiplicative character } \chi, \text{ and so } \prod_{\chi \neq 1} \tau_K(\chi)\tau_K(\overline{\chi}^d) = \pm q^{g-2}. \]

**Corollary 4.2.** Let \( L \) be a finite extension of \( K \). For a positive integer \( d \),
\[ V_{L,d} \leq [L : K] \times V_{K,d} \]

**Proof.** Denoting by \( N_{L/K} \) the norm from \( L \) over \( K \), we know by the Hasse-Davenport relation (see [13]) that
\[ -\tau_L(\chi \circ N_{L/K}) = (-\tau_K(\chi))^{[L:K]}, \]
and the set of lifted characters \( \chi \circ N_{L/K} \) as \( \chi \) runs through the nontrivial elements of \( \hat{K} \times \) is a subset of the nontrivial elements of \( \hat{L} \times \).

The remaining results in this section are specific to quadratic extensions of finite fields, which are involved in our three main results (Theorems 1.4, 1.7, and 1.9).

**Lemma 4.3.** Let \( K \) be a finite field, and let \( L \) be the quadratic extension of \( K \). Let \( d \) be degenerate over \( K \), but not over \( L \). Let \( Y \) be a set of representatives of cosets of \( K^\times \) in \( L^\times \). Then for \( a \in L \), we have
\[ W_{L,d}(a) = |K| (Z(a) - 1), \]
where \( Z(a) \) is the number of \( y \in Y \) such that \( \text{Tr}_{L/K}(y^d + ay) = 0 \).

**Proof.** If \( K \) has characteristic \( p \), then Lemma 3.2 allows us to replace \( d \) with \( p^j d \) for any \( j \), so we may take \( d \equiv 1 \pmod{|K^\times|} \) without loss of generality. Then
\[ W_{L,d}(a) = 1 + \sum_{y \in Y} \sum_{x \in K^\times} \psi_L((y^d + ay)x) \]
\[ = -|K| + \sum_{y \in Y} \sum_{x \in K} \psi_K(x \text{Tr}_{L/K}(y^d + ay)), \]
since \( |Y| = (|L| - 1)/(|K| - 1) = |K| + 1 \). The sum over \( x \) is \( |K| \) when \( \text{Tr}_{L/K}(y^d + ay) = 0; \) otherwise the sum is 0.

This calculation has immediate consequences for the \( p \)-adic valuation of Weil sum values.

**Corollary 4.4.** Let \( K \) be a finite field of characteristic \( p \), and let \( L \) be the quadratic extension of \( K \). Let \( d \) be degenerate over \( K \), but not over \( L \). Then
\[ V_{L,d} = [K : F_p], \]
and furthermore, \( W_{L,d}(a) = -|K| \) for some \( a \in L^\times \).

**Proof.** Let \( Y \) and \( Z(a) \) be as defined in Lemma 4.3 which tells us that
\[ W_{L,d}(a) = |K| (Z(a) - 1), \]
for each \( a \in L \). All these numbers have a valuation greater or equal to \( [K : F_p] \). Since \( d \) is not degenerate over \( L \), \( W_{L,d}(a) \) must be negative for
some $a \in L^\times$ by Corollary 4.3. The only way to make $W_{L,d}(a)$ negative is to have $Z(a) = 0$, which makes $W_{L,d}(a) = -|K|$, and then the valuation of $W_{L,d}(a)$ is precisely $[K : \mathbb{F}_p]$. □

The calculation of Lemma 4.3 also gives a nonnegativity condition that will be useful in our proof of Theorem 1.9.

**Corollary 4.5.** Let $K$ be a finite field, and let $L$ be the quadratic extension of $K$. Let $d$ be degenerate over $K$. Then $W_{L,d}(a) \geq 0$ for all $a \in K$.

**Proof.** We may take $d$ nondegenerate over $L$, since (2) settles the degenerate case. Let $a \in K$. By Lemma 4.3 it suffices to find some $y \in L^\times$ such that $\text{Tr}_{L/K}(y^d + ay) = 1$. In characteristic 2, take $y \in K^\times$, so that $\text{Tr}_{L/K}(y^d + ay) = 2(y^d + ay) = 0$. In odd characteristic, take $y \in L$ with $y^2 \in K$ but $y \notin K$. Then $y$ and $-y$ are conjugates under the action of $\text{Gal}(L/K)$, and so $\text{Tr}_{L/K}(y^d + ay) = (-y)^d + a(-y) + y^d + ay = 0$. □

5. Action of Galois Groups of Cyclotomic Fields

Throughout this section, $\zeta_p$ denotes a primitive $p$th root of unity over $\mathbb{Q}$. If $K$ is a field of characteristic $p$, then the Weil sum values $W_{K,d}(a)$ reside in $\mathbb{Q}(\zeta_p)$ by definition (1). First we see how Galois automorphisms permute the Weil sum values. Recall that we always have $d$ invertible modulo $|K^\times|$ whenever we write the sum $W_{K,d}$.

**Lemma 5.1.** Let $K$ be a finite field of characteristic $p$. If $\sigma$ is the element of $\text{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q})$ with $\sigma(\zeta_p) = \zeta_p^\delta$, then $\sigma(W_{K,d}(a)) = W_{K,d}(a^{1/(1/d)})$, where $1/d$ indicates the multiplicative inverse of $d$ modulo $p - 1$.

**Proof.** This is [28, Theorem 2.1(b)]. □

This shows that if two Weil sum values are Galois conjugates over $\mathbb{Q}$, then they occur equally often.

**Corollary 5.2.** Let $K$ be a finite field, and let $A$ and $B$ be values assumed by $W_{K,d}$. If $A$ and $B$ are Galois conjugates over $\mathbb{Q}$, then the number of $a \in K^\times$ such that $W_{K,d}(a) = A$ is equal to the number of $a \in K^\times$ such that $W_{K,d}(a) = B$.

**Proof.** Let $\sigma \in \text{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q})$ with $\sigma(A) = B$, and let $j \in \mathbb{F}_p^\times$ such that $\sigma(\zeta_p) = \zeta_p^j$. By Lemma 5.1, $W_{K,d}(a) = A$ precisely when $W_{K,d}(j^{-(1/d)}a) = B$. □

Often the Weil sums lie in a proper subfield of $\mathbb{Q}(\zeta_p)$. We give a criterion for determining when this happens.

**Lemma 5.3.** Let $K$ be a finite field of characteristic $p$. Let $E$ be the extension of $\mathbb{Q}$ generated by all the values of $W_{K,d}(a)$ for $a \in K^\times$. Let $m$ be the smallest divisor of $p - 1$ such that $d \equiv 1 \pmod{(p - 1)/m}$. Then $E$ is the unique subfield of $\mathbb{Q}(\zeta_p)$ with $[E : \mathbb{Q}] = m$. 
Proof. An arbitrary \( \sigma \in \text{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q}) \) takes \( \zeta_p \) to \( \zeta_j^p \) for some \( j \in \mathbb{F}_p^\times \). So by Lemma 5.1, we have

\[
\sigma^n(W_{K,d}(a)) = W_{K,d}(j^{n(1-1/d)}a)
\]

for any \( a \in K^\times \) and \( n \in \mathbb{Z} \).

Since \( d \equiv 1 \pmod{(p-1)/m} \), we see that \( j^{m(1-1/d)} = 1 \) for any \( j \in \mathbb{F}_p^\times \). Thus if \( \sigma \in \text{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q}) \), then \( \sigma^m \) fixes all the values of \( W_{K,d} \). So the subgroup of index \( m \) in \( \text{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q}) \) fixes all values in \( E \), and so \( [E : \mathbb{Q}] \) is a divisor of \( m \).

Conversely, if we set \( n = [E : \mathbb{Q}] \) and Fourier transform both sides of (5) with a multiplicative character \( \chi \in \hat{K}^\times \), we obtain

\[
\sum_{a \in K^\times} W_{K,d}(a) \chi(a) = \sum_{a \in K^\times} W_{K,d}(j^{n(1-1/d)}a) \chi(a).
\]

The left hand side is nonzero, since it is either \( q \) (if \( \chi \) is principal, cf. Lemma 2.1(ii)), or a product of Gauss sums involving nontrivial characters (use (4) with \( \chi_{1/d} \) in place of \( \chi \)). The right hand side is \( \bar{\chi}(j^{n(1-1/d)}) \) times the left hand side. Thus we must have \( \chi(j^{n(1-1/d)}) = 1 \) for all \( j \in \mathbb{F}_p^\times \) and all \( \chi \in \hat{K}^\times \), which forces \( d \equiv 1 \pmod{(p-1)/m} \). By the minimality of \( m \), this means that \( [E : \mathbb{Q}] = n \geq m \). \( \Box \)

Remark 5.4. Values of \( W_{K,d} \) are always algebraic integers, so that if these lie in a field \( E \), they actually lie in the ring of algebraic integers in \( E \).

Remark 5.5. In view of the previous remark, the special case of Lemma 5.3 when \( m = 1 \) states that the values of \( W_{K,d}(a) \) for \( a \in K^\times \) all lie in \( \mathbb{Z} \) if and only if \( d \equiv 1 \pmod{p-1} \). This was proved in [21, Theorem 4.2].

The next result is reminiscent of the power moments of Section 2. We shall combine it with Lemma 5.1 in Corollary 5.7 below.

Lemma 5.6. Let \( K \) be a finite field. For any \( b \in K \) with \( b \neq 1 \), we have

\[
\sum_{a \in K^\times} W_{K,d}(a) W_{K,d}(ba) = 0.
\]

Proof. Since \( W_{K,d}(0) = 0 \), we may include the \( a = 0 \) term in

\[
\sum_{a \in K^\times} W_{K,d}(a) W_{K,d}(ba) = \sum_{x,y \in K} \psi_K(x^d + y^d) \sum_{a \in K} \psi_K(a(x + by))
\]

\[
= |K| \sum_{x,y \in K, x+by=0} \psi_K(x^d + y^d)
\]

\[
= |K| \sum_{y \in K} \psi_K(y^d(1 + (-b)^d)),
\]

which vanishes because \( y \mapsto y^d \) is a permutation of \( K \), and \( 1 + (-b)^d \neq 0 \) since \( b \neq 1 \). \( \Box \)
Now we combine Lemmas 5.1 and 5.6.

**Corollary 5.7.** If $K$ is a finite field and $\sigma \in \text{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q})$ permutes the values of $W_{K,d}$ nontrivially, then

$$\sum_{a \in K^\times} W_{K,d}(a)\sigma(W_{K,d}(a)) = 0.$$ 

**Proof.** Lemma 5.1 furnishes an element $b$ such that $\sigma(W_{K,d}(a)) = W_{K,d}(ba)$ for all $a \in K^\times$, and clearly $b \neq 1$, for otherwise $\sigma$ would fix each value taken by $W_{K,d}$. Lemma 5.6 finishes the proof. $\square$

6. **Proof of Theorem 1.4**

We have three fields $I \subseteq J \subseteq K$ with $[J : I] = 2$. Let $p$ be the characteristic of our fields. As always, $\gcd(d, |K^\times|) = 1$. We are given that $d$ is degenerate in $I$, but not in $J$.

We want to show that the value set of $W_{K,d}$ is not of the form $\{0, \pm A\}$. Suppose the contrary. By Proposition 2.4, $|A|$ must be an integral power of $p$ with $\sqrt{|K|} < |A| < |K|$, so then

$$V_{K,d} = \text{val}_p(A)$$

$$> \text{val}_p(\sqrt{|K|})$$

$$= \frac{1}{2}[K : F_p].$$

On the other hand, by Corollary 4.2 and Corollary 4.4, we get a contradiction because

$$V_{K,d} \leq [K : J] \times V_{J,d}$$

$$= [K : J] \times [I : F_p]$$

$$= \frac{1}{2}[K : F_p].$$

7. **Proof of Theorem 1.7**

We have $K$ a finite field of characteristic $p$ and order $q$ with $[K : F_p]$ divisible by $2^s$. As always, $\gcd(d, q - 1) = 1$. We suppose that $W_{K,d}$ is symmetric three-valued with values 0 and $\pm A$, and our goal is to show that $|A| \geq p^{2^s-1} \sqrt{q}$.

Note that $F_{p^{2^s}} \subseteq K$. Since $W_{K,d}$ is three-valued, $d$ is degenerate over $F_p$ by Theorem 1.2. If $d$ were nondegenerate over $F_{p^{2^s}}$, then there must be subfields $I$ and $J$ of $F_{p^{2^s}}$ with $[J : I] = 2$ and $d$ degenerate over $I$ but not over $J$. Then Theorem 1.4 tells us that $W_{K,d}$ is not symmetric three-valued, contrary to our hypothesis.

So $d$ is degenerate over $F_{p^{2^s}}$, and thus every point of $F_{p^{2^s}}$ is an element of the set $R$ of roots of $(x + 1)^d - x^d - 1$. Thus $|R| \geq p^{2^s}$, so Proposition 2.4 tells us that $|A| = \sqrt{|R|q} \geq p^{2^s-1} \sqrt{q}$. 
8. Proof of Theorem 1.9

We have $L$ a finite field with $[L : \mathbb{F}_p]$ even, and $d$ is a power of $p$ modulo $\sqrt{|L|} - 1$. We want to show that $W_{L,d}$ is not three-valued.

Since we are considering $W_{L,d}$, the exponent $d$ is an invertible element modulo $|L|$. If $d$ is degenerate over $L$, then $W_{L,d}$ is at most two-valued by \([2]\), so we assume that $d$ is nondegenerate over $L$ henceforth. The proof that $W_{L,d}$ is not three-valued when $L$ is of characteristic 2 is given as \([8, \text{ Theorem 2}]\), so we assume that we are in odd characteristic henceforth.

Assume $W_{L,d}$ is three-valued to show a contradiction. By Theorem 1.2 and Corollary \([2.3]\), these three values are all in $\mathbb{Z}$, one of them is 0, one is positive, and one is negative. Let $K$ and Corollary 2.3, these three values are all in $\mathbb{Z}$, so we assume that we are in odd characteristic henceforth.

Then by Corollary 4.5, we know that $W_{L,d}$ acts transitively, or (iii) fixes the third. As $A$, $B$, $C$, is contained in the cyclic extension $\mathbb{Q}$, it is a cyclic Galois extension of $\mathbb{Q}$ since it is contained in the cyclic extension $\mathbb{Q}(\zeta_p)$ of $\mathbb{Q}$. Let $\sigma$ be a generator of $\text{Gal}(\mathbb{Q}(A,B,C)/\mathbb{Q})$. There are three possible actions of $\sigma$ upon $\{A, B, C\}$: (i) $\sigma$ is the identity permutation, (ii) $\sigma$ acts transitively, or (iii) $\sigma$ permutes a pair of these elements, and fixes the third. As $A$, $B$, and $C$ are algebraic integers, they lie in $\mathbb{Z}$ if and only if they lie in $\mathbb{Q}$, and this occurs precisely in Case (i), it suffices to show that Cases (ii) and (iii) are impossible.

In Case (ii), Corollary 5.2 tells us that $N_A = N_B = N_C$, so they all equal $(q-1)/3$. Then Lemma 2.11 tells us that $N_A A + N_B B + N_C C = q$, so that $A + B + C = 3 + \frac{q}{3}$. As $A + B + C$ is fixed by $\sigma$, it lies in $\mathbb{Q}$, and is at the same time an algebraic integer, so it lies in $\mathbb{Z}$. This means that $q - 1 \mid 3$, which forces $p = 2$, in which case $\zeta_p = -1$, and so the values of $W_{K,d}$ lie...
in $\mathbb{Z}$, contradicting our supposition that $\sigma$ permutes them nontrivially. So Case (ii) is impossible.

Henceforth, we suppose that we are in Case (iii). Without loss of generality, we suppose that the generator $\sigma$ of $\text{Gal}(\mathbb{Q}(A,B,C)/\mathbb{Q})$ has $\sigma(A) = B$, $\sigma(B) = A$, and $\sigma(C) = C$. Then $\sigma$ is of order 2, and so $\mathbb{Q}(A,B,C)$ is a quadratic extension of $\mathbb{Q}$ lying in $\mathbb{Q}(\zeta_p)$. There is no such thing if $p = 2$ (since $\zeta_p = -1$, so $\mathbb{Q}(\zeta_p) = \mathbb{Q}$). Otherwise, since $\mathbb{Q}(\zeta_p)$ is cyclic of degree $p - 1$ over $\mathbb{Q}$, this means that $\mathbb{Q}(A,B,C)$ is the unique quadratic extension of $\mathbb{Q}$ contained in $\mathbb{Q}(\zeta_p)$. In view of the values of the quadratic Gauss sums \[ \chi \], we know that this unique quadratic extension must be $\mathbb{Q}(\sqrt{p})$ if $p \equiv 1 \pmod{4}$, or $\mathbb{Q}(\sqrt{-p})$ if $p \equiv 3 \pmod{4}$. But since $A, B$, and $C$ are real (see \[ \text{[21] Theorem 3.1(a)} \] or \[ \text{[28] Theorem 2.1(c)} \]), the latter case is impossible, so we must have $p \equiv 1 \pmod{4}$ and $\mathbb{Q}(A,B,C) = \mathbb{Q}(\sqrt{p})$. Then $C \in \mathbb{Z}$, since it is an algebraic integer fixed by $\sigma$, and $A = a + b\sqrt{p}$ and $B = a - b\sqrt{p}$, for some $a, b$ with $2a$, $2b$, and $a + b \in \mathbb{Z}$, since this is the form of algebraic integers in $\mathbb{Q}(\sqrt{p})$, as shown in \[ \text{[33] Chapter IV, Theorem 2.3} \].

Then Lemma \[ \text{[21] (ii)} \] tells us that

\begin{align*}
&\quad \quad (6) \quad N_A A + N_B B + N_C C = q, \\
&\quad \quad (7) \quad N_A A^2 + N_B B^2 + N_C C^2 = q^2.
\end{align*}

Also \[ \sum_{a \in K^*} W_{K,d}(a)\sigma(W_{K,d}(a)) = 0 \] by Corollary \[ \text{[5.7]} \] so

\begin{align*}
&\quad \quad (8) \quad N_A AB + N_B BA + N_C C^2 = 0.
\end{align*}

By Corollary \[ \text{[5.2]} \] we have $N_A = N_B$, and since $A = a + b\sqrt{p}$ and $B = a - b\sqrt{p}$, our three equations (6), (7), and (8) become

\begin{align*}
&\quad \quad 2N_A a + N_C C = q, \\
&\quad \quad 2N_A (a^2 + pb^2) + N_C C^2 = q^2, \\
&\quad \quad 2N_A (a^2 - pb^2) + N_C C^2 = 0,
\end{align*}

and this system is equivalent to the system

\begin{align*}
&\quad \quad (9) \quad 2N_A a + N_C C = q, \\
&\quad \quad (10) \quad 4N_A a^2 + 2N_C C^2 = q^2, \\
&\quad \quad (11) \quad 4N_A pb^2 = q^2.
\end{align*}

From \[ \text{[11]} \] we see that $p \mid N_A$. Note that $C \neq 0$, since otherwise \[ \text{[9]} \] and \[ \text{[10]} \] imply that $N_A = 1$, contradicting $p \mid N_A$. If we subtract \[ \text{[10]} \] from $2(a + C)$ times equation \[ \text{[9]} \], we obtain

\begin{equation*}
2(2N_A + N_C)aC = q(2a + 2C - q),
\end{equation*}

and since $N_A + N_B + N_C = q - 1$, with $N_A = N_B$, this gives

\begin{equation*}
2(q - 1)aC = q(2a + 2C - q).
\end{equation*}

Examine the $p$-adic valuation of each side of this equation to see that $\max\{\text{val}_p(a), \text{val}_p(C)\} \geq \text{val}_p(q)$. Then by Corollary \[ \text{[2.2]} \] we see that $|C| < q$,
and since $C \neq 0$, we must have $\text{val}_p(C) < \text{val}_p(q) \leq \text{val}_p(a)$, so that $q \mid 2a$. If we reduce $q$ modulo $q$, we see that $q \mid NC$, but since $q \nmid C$, we have $p \mid NC$. Thus $p \mid NA$ and $p \mid NC$, and so $p \mid (2NA + NC) = q - 1$, which is absurd. Thus Case (iii) is impossible, and the proof is complete.
