The effective electroweak mixing angle $\sin^2 \theta_W$ is measured from the production and decay of the Z boson in $e^+e^-$ interactions. The data sample corresponds to an integrated luminosity of 18 pb$^{-1}$ with about 420000 hadronic and 40 000 leptonic Z decays. The mixing angle $\sin^2 \theta_W$ is determined from several independent measurements: the leptonic and hadronic cross sections, the forward-backward asymmetries of charged leptons and b-quarks, and the $r$-polarization. The results are found to be in good agreement with each other. The value of $\sin^2 \theta_W$ from a fit to the asymmetries in a model independent method is $0.2321 \pm 0.0021$ and from a global fit to the data in the Standard Model framework is $0.2328 \pm 0.0013$.

Deceased.
1. Introduction

In the Standard Model of electroweak interactions [1], the electroweak mixing angle, \( \theta_W \), describes the mixing of the gauge fields \( W_3 \) and \( B \) of the local gauge group \( SU(2)_L \times U(1) \). For the calculation of electroweak processes between fermions, four basic input parameters are required apart from fermion masses and quark mixing angles. The on-shell renormalisation scheme uses \( \alpha, M_W, M_Z \) and the mass of the Higgs particle as input parameters. QCD [2] adds one more parameter, the strong coupling constant \( \alpha_s \). The electroweak mixing angle is defined by the relation

\[
\sin^2 \theta_W = 1 - \frac{M_W^2}{M_Z^2},
\]

where \( M_W \) and \( M_Z \) are the physical masses of the W and Z boson.

The Z mass is measured from the peak position of the Z lineshape at LEP with high precision [3,4]. \( \alpha_s \) is determined at LEP from analysis of hadronic Z decays [5]. An additional constraint can be obtained from the Fermi coupling constant, \( G_F \), measured in muon decay. As \( \alpha_s \) is well determined, the Standard Model still requires two unknown parameters, typically taken as the mass of the top quark, \( M_t \), and the mass of the Higgs particle, \( M_H \). One can consider \( \sin^2 \theta_W \) instead of \( M_t \) as a free parameter. The effect of the Higgs mass on cross sections and asymmetries is rather small. At LEP we measure the effective electroweak mixing angle, \( \sin^2 \theta_w \), which includes weak radiative corrections.

In this paper, we use the measurements of the cross sections of hadrons and charged leptons [3], the forward-backward asymmetries of the charged leptons (\( A_{FB} \)) [3] and bottom quarks (\( A_{FB} \)) [6], and the \( \tau \)-polarization asymmetry (\( A_{\tau} \)) [7] for a precise determination of the electroweak mixing angle. We test if the Standard Model describes the different measurements with a unique value of the electroweak mixing angle.

2. Effective coupling constants

It is important to determine the electroweak parameters independently of assumptions about the two unknown parameters, \( M_t \) and \( M_H \). The model independent approach introduces an additional parameter \( \rho \) which denotes the ratio of the neutral to charged current coupling constants. This ratio is unity in the Standard Model at the tree level. Radiative corrections can be separated into QED corrections and weak corrections. The QED corrections, which depend on the acceptance of the detector and on cuts used in the analysis, are always taken into account for calculating the theoretical predictions. Since the weak corrections cannot be calculated outside the framework of the Standard Model, we do not apply weak corrections, but absorb them into the definition of the fitted parameters. As a result, at LEP one measures the effective electroweak mixing angle, \( \sin^2 \theta_w \), where \( f \) denotes the flavour, which absorbs the weak corrections

\[
\sin^2 \theta_w = k_f \sin^2 \theta_w, \quad (2)
\]

\( k_f \) accounts for all weak corrections. Standard Model calculations show that \( k_f \) is flavour independent within 0.04% with the exception of b-quarks. We, therefore, take \( \sin^2 \theta_w \) to be the effective electroweak mixing angle for all fermions except b-quarks. For b-quarks the vertex correction is large due to the virtual top quark contribution. The two determinations of \( \sin^2 \theta_w \) can be related by [8]

\[
\sin^2 \theta_w = (1 + \frac{3}{2} \Delta \rho) \sin^2 \theta_w, \quad (3)
\]
\[
\Delta \rho \approx 3 G_F M_t^2 / 8 \pi^2 \sqrt{2}. \quad (4)
\]

For \( M_t = 150 \text{ GeV} \) the value of \( \sin^2 \theta_w \) is 0.4% larger than \( \sin^2 \theta_w \). The parameter \( \rho \) (\( \rho \equiv 1 + \Delta \rho \)) is the effective \( \rho \) parameter.
The effective vector and axial-vector couplings of the Z to light fermion pairs are given by

\[ g_v = \sqrt{3} f \left( I_3 - 2Q \sin^2 \theta_w \right), \]
\[ g_a = \sqrt{3} \left( I_3 - 2Q \sin^2 \theta_w \right), \]

where \( I_3 \) and \( Q \) are respectively the weak isospin and charge of the fermion.

The expressions for \( A_{FB}^\nu, A_{FB}^b \) and \( P_t \) in terms of \( \sin^2 \theta_w \) at \( \sqrt{s} = M_Z \) are \[9\]

\[ A_{FB}^\nu(M_Z^2) = \frac{3(1 - 4 \sin^2 \theta_w)^2}{\left[ 1 + (1 - 4 \sin^2 \theta_w)^2 \right]^2 + \left( \frac{B_\nu}{\sqrt{b}} \right)^2 M_Z^2}, \]
\[ A_{FB}^b(M_Z^2) = \frac{3(1 - 4 \sin^2 \theta_w)^2 \beta (1 - \frac{3}{2} \sin^2 \theta_w)}{\left[ 1 + (1 - 4 \sin^2 \theta_w)^2 \right]^2 + \left( \frac{B_\nu}{\sqrt{b}} \right)^2 M_Z^2}, \]
\[ P_t(M_Z^2) = -\frac{2(1 - 4 \sin^2 \theta_w)(1 + (1 - 4 \sin^2 \theta_w)^2)}{\left[ 1 + (1 - 4 \sin^2 \theta_w)^2 \right]^2 + \left( \frac{B_\nu}{\sqrt{b}} \right)^2 M_Z^2}, \]

where \( \beta = \sqrt{(1 - 4M_b^2/M_Z^2) \beta_0} \), \( M_b \) is the mass of the b-quark, \( K = 16 \sin^4 \theta_w \cos^2 \theta_w \) and \( B_\nu \) and \( B_\nu^b \) are the \( b \)-parameters for the leptons and b-quarks. In the above expressions, for the sake of clarity, the correction due to photon vacuum polarization has been omitted. For comparison with data we use the complete s-dependent expressions with QED corrections which take into account initial and final state radiation.

3. The L3 detector

The fiducial solid angle of the L3 detector \[10\] is 99% of 4\( \pi \). L3 consists of a time expansion chamber (TEC) for tracking charged particles, a high resolution electromagnetic calorimeter of BGO crystals, a barrel of scintillation counters, a hadron calorimeter with uranium absorber and proportional wire chamber readout and a muon spectrometer. The luminosity is determined from small-angle Bhabha scattering using BGO electromagnetic calorimetry in the polar angle ranges \( \theta \) and \( \pi - \theta \) between 24.93 and 69.94 mrad. All subdetectors are installed inside a 12 m diameter solenoidal magnet which provides a uniform 0.5 T field along the beam direction.

4. Event selection

We briefly summarize the selection of various types of events; for details see refs. \[3,6\].

- The selection of \( e^+ e^- \rightarrow e^+ e^- (\gamma) \) events is based mainly on information from the electromagnetic calorimeter. Background from hadronic events is suppressed by requiring that events have less than \( 8 \) reconstructed clusters in the electromagnetic calorimeter, and \( \tau^+ \tau^- \) events are rejected by requiring that the most energetic cluster in the electromagnetic calorimeter has energy \( > 0.85 E_{\text{beam}} \).

- Events of type \( e^+ e^- \rightarrow \mu^+ \mu^- (\gamma) \) are required to have two tracks in the muon chamber system with one muon track with momentum greater than \( \frac{3}{2} E_{\text{beam}} \). Cosmic ray background is removed by demanding the muon track to be within 3 nsec of the beam gate.

- The selection of \( e^+ e^- \rightarrow \tau^+ \tau^- (\gamma) \) events requires the total energy in the electromagnetic calorimeter to be larger than 2 GeV and the two most energetic electromagnetic clusters to have energies below 90% and 65% of the beam energy. This removes background from \( e^+ e^- \) final states. Similarly the background from \( \mu^+ \mu^- \) is suppressed by requiring that the momentum measured in the muon chambers is less than 0.9 \( E_{\text{beam}} \) for the most energetic and 0.4 \( E_{\text{beam}} \) for the second most energetic muon candidate in the event. Hadronic events are suppressed by applying an upper limit of 12 calorimeter clusters.
The event selection for e⁺e⁻ → hadrons is based on the energy depositions in the electromagnetic and hadronic calorimeters. Backgrounds due to beam–wall interactions, beam–gas interactions, two-photon events and cosmic ray showers are suppressed by cuts on the total visible energy, \( E_{\text{vis}} \), and by restricting the longitudinal and transverse energy imbalances to \( |E_l|/E_{\text{vis}} < 0.6 \) and \( |E_t|/E_{\text{vis}} < 0.5 \).

Hadronic events are used to further select e⁺e⁻ → bb. We use electrons and muons from the semileptonic decay of b-quark to select these events. Because of the hard fragmentation and large mass of the b-quark, leptons from b-quark decay have large momentum \( p \) as well as large transverse momentum \( p_T \) with respect to the nearest jet. By putting a lower limit on both \( p \) (3–4 GeV) and \( p_T \) (1 GeV), bb event selection purity reaches 85%.

5. Results

This analysis is based on the following sets of data, summarized in tables 1 to 3, corresponding to an integrated luminosity of \( \simeq 18 \) pb⁻¹, collected with the L3 detector at LEP in 1990–91:
- 4 sets of cross section measurements of \( e^+e^- \rightarrow e^+e^-, \mu^+\mu^- \), \( \tau^+\tau^- \) and hadrons [5];
- 3 sets of forward–backward asymmetry measurements of charged leptons \( \mathcal{A}_{FB} \) in \( e^+e^- \rightarrow e^+e^-, \mu^+\mu^- \) and \( \tau^+\tau^- \) [5];
- Forward–backward asymmetry of b-quark in \( e^+e^- \rightarrow b\bar{b} \) [6];
- Measurement of \( \tau \)-polarization [7].

To fit the data, we use ZFITTER [11] in the L3 lineshape fitting program which uses MINUIT [12] for minimisation. ZFITTER takes into account initial and final state photon radiation and corrections due to photon vacuum polarization. Two separate fitting procedures are followed:

| \( \sqrt{s} \) (GeV) | \( \sigma_{\text{had}} \) (nb) | \( \sigma_{\text{lept}} \) (nb) | \( \sigma_{\mu\mu} \) (nb) | \( \sigma_{\tau\tau} \) (nb) |

Standard Model fit: QED as well as weak radiative corrections are taken from the Standard Model. The free parameters are $M_Z$, top quark mass ($M_t$), Higgs boson mass ($M_H$) and the strong coupling constant ($\alpha_s$). In this fit ZFITTER accounts for contributions up to $O(\alpha_s)$ and $O(M^4)$.  

Model Independent Method: QED corrections are taken into account with an energy dependent Breit–Wigner shape for the determination of Z parameters. A slight dependence on the Standard Model parameters $M_t$ and $M_H$ enters into this method for the calculation of the $\gamma$–Z interference term, and the t-channel and s–t interference terms in $e^+e^- \rightarrow e^+e^-$. The effect of this is studied by changing $M_t$ in the range 90 to 250 GeV and $M_H$ from 60 to 1000 GeV. The fitted value of $M_Z$ changes by $\pm 0.1$ MeV; the change in other parameters is found to be less than 5% of their error.

We have used the model independent method to determine the mass, the total width and partial widths by fitting the total cross sections for $e^+e^- \rightarrow e^+e^-, \mu^+\mu^-$, $\tau^+\tau^-$ and hadrons. In addition to the experimental errors, which include statistical and systematic uncertainties, we have taken into account the errors on the center
of mass energy as estimated by the LEP energy working group [13]. The fitted values of the Z mass, total width and partial widths thus obtained are, with \( \chi^2/\text{DOF} = 53/56 \):

\[
M_Z = 91195 \pm 9 \text{ MeV}, \\
\Gamma_Z = 2490 \pm 11 \text{ MeV}, \\
\Gamma_h = 1747 \pm 11 \text{ MeV}, \\
F_t = 83.1 \pm 0.5 \text{ MeV}.
\]

5.1. \( \sin^2 \theta_w \) in the standard model framework

In this section we describe the determination of \( \sin^2 \theta_w \) in the Standard Model framework. Fits are carried out using ZFITTER with \( M_Z \) and \( M_t \) as the free parameters. \( \sin^2 \theta_w \) is then determined using the Standard Model relation. The data are fitted with a fixed value of \( M_H = 300 \text{ GeV} \) and constraining the value of \( \alpha_s \) to 0.124±0.006 [5]. The effect of \( M_H \) is studied by varying it from 60 GeV to 1000 GeV. This effect is found to be \( \pm 0.0001 \) in \( \sin^2 \theta_w \). The results from the following fits are summarized in table 4.

\( \sin^2 \theta_w \) from \( \Gamma \): Here we fit to the measured value of \( \Gamma \) obtained from the model independent fit to the cross section data. In addition we constrain \( M_Z \) to the measured value.

\( \sin^2 \theta_w \) from \( \Gamma \): The fit is carried out using the measured value of \( \Gamma \) and \( M_Z \) from the cross section data.

\( \sin^2 \theta_w \) from \( A_{FB} \): In these fits we use (i) the asymmetry data from charged leptons, (ii) \( A_{FB} \), (iii) \( P_t \) and (iv) all the asymmetry data \( A_{FB}, A_{FB}^b \) and \( P_t \). \( M_Z \) is constrained to the measured value given above.

\( \sin^2 \theta_w \) from cross section and asymmetry measurements: Here we perform a global fit to all the data, that is, the cross section data, the charged lepton asymmetries, the b\(b\) asymmetry and the \(r\)-polarization, in the framework of the Standard Model. A good fit is obtained with \( \chi^2/\text{DOF} = 84/105 \).

The values of \( \sin^2 \theta_w \) and \( M_t \) determined with the global fit in the Standard Model framework are:

\( \sin^2 \theta_w = 0.2328 \pm 0.0013 \pm 0.0001 \),

\( M_t = 152^{+36}_{-46} \pm 20 \text{ GeV} \),

corresponding to a value of \( \sin^2 \theta_w \), as defined in eq. (1), to be 0.2268 \( ^{+0.0050}_{-0.0043} +^{0.0003}_{-0.0004} \). The second error corresponds

Table 4

| Measurements used | \( \sin^2 \theta_w \) |
|-------------------|---------------------|
| \( M_Z, \, \Gamma \) | 0.2351±0.0009 |
| \( M_Z, \, \Gamma_Z \) | 0.2330±0.0017 |
| \( M_Z, \, A_{FB} \) | 0.2279±0.0035 |
| \( M_Z, \, A_{FB} \) | 0.2335±0.0035 |
| \( M_Z, \, \Gamma \) | 0.2326±0.0034 |
| \( M_Z, \, A_{FB}^b, \, A_{FB}^b, \, P_t \) | 0.2319±0.0022 |
| all data | 0.2328±0.0013 |

458
to a variation of the Higgs mass between 60 and 1000 GeV. Fig. 1 shows contour plots of $\sin^2 \theta_w$ versus $M_Z$, and $\sin^2 \theta_w$ versus $M_t$ at the 68% CL for different values of $M_h$.

5.2. $\sin^2 \theta_w$ in the model independent method

In this section we describe the model independent determination of $\sin^2 \theta_w$ using all the asymmetry data and the four cross section data sets. The cross sections determine the mass and total width of $Z$, while the asymmetries measure $\sin^2 \theta_w$. The dependence of the asymmetries on $\sin^2 \theta_w$ are described by eqs. (7)–(9); they depend weakly on $M_Z$ and $F_Z$. Fits have been carried out using ZFITTER in the model independent method. Lepton universality is assumed in carrying out the fits. The results are summarized in table 5.

$\sin^2 \theta_w$ from $A_{FB}$: Here we use the 3 sets of forward–backward asymmetry measurements ($A_{FB}$) along with the four sets of cross section data. Free parameters of the fit are: $M_Z$, $I_Z$, $I_\nu$, $\bar{p}$ and $\sin^2 \theta_w$.

$\sin^2 \theta_w$ from $A_{FB}$: In this fit we use the $bb$ asymmetry measurements together with the cross section data.

Compared to the $A_{FB}$ case, we need $\sin^2 \theta_w$ and $\bar{p}$ for $A_{FB}$ as in eq. (8). We rewrite $\sin^2 \theta_w$ in terms of $\sin^2 \theta_w$ and $M_t$ using eq. (3) and take $\bar{p}$ from the Standard Model. Thus our free parameters of the fit are the same as above. The effect of $M_t$ on the fitted $\sin^2 \theta_w$ is studied by varying it from 90 to 250 GeV, and it is found to change the fitted value by less than 0.0001. We have also studied the effect of $M_t$ arising from eq. (3) by refitting the data for a fixed value of $\bar{p}$. We find that the variation in $M_t$ from 0 to 250 GeV changes $\sin^2 \theta_w$ by only 0.00004. Thus at current precision we can replace $\sin^2 \theta_w$ by $\sin^2 \theta_w$ in eq. (8) [14].

$\sin^2 \theta_w$ from $P_t$: The free parameters in this case are identical to the first case.

$\sin^2 \theta_w$ from $A_{FB}$, $P_t$: The fitted values of $\sin^2 \theta_w$, as measured in the above three cases, refer to the same definition of $\sin^2 \theta_w$ [15]. Hence to get the best value of $\sin^2 \theta_w$ from our asymmetry measurements we carry out a simultaneous fit to all the three types of the asymmetry data along with the cross section data assuming lepton universality.

The combined fit to all data in the model independent method yields

---

#1 We have repeated the fits by using only the asymmetry data and by constraining $M_Z$ and $I_\nu$ to our measured values. In this procedure, one needs to assume $\bar{p}$ from the Standard Model. The values of $\sin^2 \theta_w$ thus obtained are found to differ from the values quoted in table 5 by less than 0.0001. The effect of taking $\bar{p}$ from the Standard Model is studied by changing $M_t$ from 90 to 250 GeV, and it is found to change the fitted value of $\sin^2 \theta_w$ by less than 0.00002.
Table 5
sin²θ̃_w determined in the model independent method.

| Measurements used | χ²/DOF | sin²θ̃_w | ¯ρ       |
|-------------------|--------|----------|----------|
| σ's, A_{FB}       | 82/100 | 0.2283 ± 0.0036 | 0.9933 ± 0.0063 |
| σ's, A_{FB}        | 55/58  | 0.2336 ± 0.0029  | 0.9961 ± 0.0063  |
| σ's, F_t           | 53/56  | 0.2326 ± 0.0043  | 0.9956 ± 0.0065  |
| σ's, A_{FB}, A_{FB}, F_t | 86/104 | 0.2321 ± 0.0021  | 0.9957 ± 0.0060  |

Fig. 2. 68% and 95% confidence level contours of sin²θ̃_w versus ¯ρ obtained from a fit to the L3 data in the model independent approach. The lines indicate Standard Model predictions for various top and Higgs masses. The open circles correspond to top mass values of 100 and 200 GeV.

sin²θ̃_w = 0.2321 ± 0.0021,
¯ρ = 0.9957 ± 0.0060.

Fig. 2 shows the 68% and 95% confidence level contour plots of sin²θ̃_w versus ¯ρ together with Standard Model predictions.

6. Conclusions

From a data sample of 420 000 hadronic and 40 000 leptonic Z decays recorded by the L3 detector we have determined the effective electroweak mixing angle, sin²θ̃_w, with several methods: (i) from Standard Model fits to M_E, M_Z and f, M_Z and f, M_Z and A_{FB}’s, (ii) from a global fit to the cross section and asymmetry data in the Standard Model framework and (iii) from A_{FB}, A_{FB} and F_t in a model independent way. The results, as summarized in fig. 3, are in very good agreement with each other.
The model independent value of $\sin^2 \theta_w$ from the three measured asymmetries is: $0.2321 \pm 0.0021$. Within the framework of the Standard Model a global fit to all the data yields $\sin^2 \theta_w = 0.2328 \pm 0.0013$.

Acknowledgement

We wish to express our gratitude to the CERN accelerator divisions for the excellent performance of the LEP machine. We acknowledge the efforts of all engineers and technicians who have participated in the construction and maintenance of this experiment.
