Abstract—Nonlinear sparse sensing (NSS) techniques have been adopted for realizing compressive sensing in many applications such as Radar imaging. Unlike the NSS, in this paper, we propose an adaptive sparse sensing (ASS) approach using reweighted zero-attracting normalized least mean fourth (RZA-NLMF) algorithm which depends on several given parameters, i.e., reweighted factor, regularization parameter and initial step-size. First, based on the independent assumption, Cramer Rao lower bound (CRLB) is derived as for the performance comparisons. In addition, reweighted factor selection method is proposed for achieving robust estimation performance. Finally, to verify the algorithm, Monte Carlo based computer simulations are given to show that the ASS achieves much better mean square error (MSE) performance than the NSS.

I. INTRODUCTION

Compressive sensing [1], [2] has been attracting high attentions in compressive Radar/sonar sensing [3], [4] due to many applications such as civilian, military, and biomedical. The main task of CS problems can be divided into three aspects as follows: 1) sparse signal learning: The basic model suggests that natural signals can be compactly expressed, or efficiently approximated, as a linear combination of prespecified atom signals, where the linear coefficients are sparse as shown in Fig. 1 (i.e., most of them zero); 2) random measurement matrix design. It is important to make a sensing matrix which allows recovery of as many entries of unknown signal as possible by using as few measurements as possible. Hence, sensing matrix should satisfy the conditions of incoherence and restricted isometry property (RIP) [5]. Fortunately, some special matrices (e.g., Gaussian matrix and Fourier matrix) have been reported that they are satisfying RIP in high probably; 3) sparse reconstruction algorithms. Based on previous two steps, many sparse reconstruction algorithms have been proposed to find the suboptimal sparse solution.

It is well known that the CS provides a robust framework that can reduce the number of measurements required to estimate a sparse signal. Many NSS algorithms and their variants have been proposed to deal with CS problems. They mainly fall into two basic categories: convex relaxation (basis pursuit de-noise, BPDN [6]) and greedy pursuit (orthogonal matching pursuit, OMP [7]). Above NSS based CS methods are either high complexity or low performance, especially in the case of low signal-to-noise (SNR) regime. Indeed, it was very hard to adaptive tradeoff between high complexity and good performance.

In this paper, we propose an adaptive sparse sensing (ASS) method using reweighted zero-attracting normalized mean fourth error algorithm (RZA-NLMF) [8] to solve the CS problems. Different from NSS methods, each observation and corresponding sensing signal vector will be implemented by the RZA-NLMF algorithm to reconstruct the sparse signal during the process of adaptive filtering. According to the concrete requirements, complexity of the proposed ASS method could be adaptive reduced but without sacrificing much recovery performance. The effectiveness of our proposed method is confirmed via computer simulation when comparing with NSS.

The remainder of the paper is organized as follows. Basic CS problem is introduced and typical NSS method is presented in Section II. In section III, ASS using RZA-NLMF algorithm is proposed for solving CS problems and its derivation process is highlighted. Computer simulations are
Assume a finite-length discrete signal vector \( s = [s_1, s_2, \cdots, s_M]^T \) can be sparse represented in a signal domain \( D \), that is
\[
s = \sum_{i=1}^{M} d_i h_i = Dh, \tag{1}
\]
where \( h = [h_1, h_2, \cdots, h_N]^T \) is the unknown \( K \)-sparse coefficients vector (\( K \ll N \)), and \( D \) is an \( N \times M \) orthogonal basis matrix with \( \{d_i, i = 1, 2, \cdots, N\} \) as its columns. Take a random measurement signal matrix \( W \) and then the received signal vector \( y = [y_1, \cdots, y_m, \cdots, y_M]^T \) can be written as
\[
y = Ws + z =WDh + z = Xh + z \tag{2}
\]
where \( X = WD \) denotes a \( M \times N \) random sensing matrix as
\[
X = \begin{bmatrix}
    x_{11} & \cdots & x_{1K} & \cdots & x_{1M} \\
    \vdots & \ddots & \vdots & \ddots & \vdots \\
    x_{m1} & \cdots & x_{mK} & \cdots & x_{mM} \\
    \vdots & \ddots & \vdots & \ddots & \vdots \\
    x_{M1} & \cdots & x_{MK} & \cdots & x_{MM}
\end{bmatrix}
\tag{3}
\]
and \( z = [z_1, \cdots, z_m, \cdots, z_M]^T \) is an additive white Gaussian noise (AWGN) with distribution \( CN(0, \sigma^2 I_M) \) and \( I_M \) denotes an \( M \times M \) identity matrix. From the perspective of CS, the sensing matrix \( X \) satisfies the restricted isometry property (RIP) in overwhelming probability [5] so that the sparse signal \( h \) can be reconstructed correctly by NSS methods, e.g., BPDN [6] and OMP [7]. Take the BPDN as for the example to illustrate NSS realization approach. Since the sensing matrix \( X \) satisfies RIP of order \( K \) with positive parameter \( \delta_K \in (0, 1) \), i.e., \( X \in \text{RIP}(K, \delta_K) \) if
\[
(1 - \delta_K) \|h\|_2^2 \leq \|Xh\|^2 \leq (1 + \delta_K) \|h\|_2^2, \tag{4}
\]
holds for all \( h \) having no more than \( K \) nonzero coefficients. Then the unknown sparse vector \( h \) can be reconstructed by BPDN as
\[
\hat{h}_{\text{BPDN}} = \text{arg min}_h \left\{ \frac{1}{2} \|y - Xh\|_2^2 + \rho \|h\|_1 \right\}, \tag{5}
\]
where \( \rho \) denotes a regularization parameter which balances the mean-square error (MSE) term and sparsity of \( h \). If the mutual interference of sensing matrix \( X \) can be completely removed, then the theoretical Cramer-Rao lower bound (CRLB) of the NSS can be derived as [9][10]
\[
\text{CRLB}\{\hat{h}_{\text{CRLB}}\} = K \frac{\sigma^2}{N}. \tag{6}
\]

**III. ADAPTIVE SPARSE SENSING**

We reconsider the above system model (2) with respect to adaptive sensing case. At observation side, \( m \)-th observed signal \( y_m \) can be written as
\[
y_m = h^T \bar{x}_m + z_m, \tag{7}
\]
for \( m = 1, 2, \cdots, M \). The objective of NSS is to adaptively estimate the unknown sparse vector \( h \) using the sensing signal vector \( x_m \) and the observed signal \( y_m \). Different from NSS approaches, we proposed an alternative ASS method using RZA-LMF algorithm as shown in Fig. 2. Assume the
\[
\tilde{e}_m(n) = y_m - \hat{e}_m(n) \tag{8}
\]
is an estimated observed signal which depends on signal estimator \( \hat{e}_m(n) \) and hence the \( n \)-th observed signal error as \( e_m(n) = y_m - \tilde{e}_m(n) \). Notice that the \( e_m(n) \) is in correspondence with the \( n \)-th iterative error when using \( m \)-th sensing signal vector \( x_m \) and \( m = \text{mod}(n, M) \). Notice that the \( \text{mod}() \) denotes a modulo function, for example, \( \text{mod}(10, 3) = 1 \) and \( \text{mod}(11, 3) = 2 \). First of all, the cost function of RZA-LMF algorithm is constructed as
\[
G(n) = \frac{1}{4} e_m^4(n) + \lambda \sum_{i=1}^{N} \log(1 + \varepsilon|h|), \tag{9}
\]
where \( \lambda > 0 \) is a regularization parameter which trades off the sensing error and coefficients vector sparsity. \( \varepsilon > 0 \) denotes a reweighted factor which enhances to exploit the signal sparsity at each iteration. A figure example to show the relationship between reweighted factors and sparse constraint strength is given in Fig. 3. According to the cost function (9), the corresponding update equation can be derived as
\[
\tilde{h}(n+1) = \tilde{h}(n) - \mu_{\text{w}} \frac{\partial G(n)}{\partial \tilde{h}(n)} = \tilde{h}(n) + \frac{\mu_{\text{w}} e_m^4(n) x_m}{\|x_m\| + e_m(n)} \frac{\rho \text{sgn}(\tilde{h}(n))}{1 + \varepsilon|\tilde{h}(n)|}, \tag{10}
\]
where \( \rho = \mu_{\text{w}} \lambda / \varepsilon \) is a parameter which depends on initial step-size \( \mu_{\text{w}} \), regularization parameter \( \lambda \) and threshold \( \varepsilon \), respectively. In the second term of (10), if coefficient magnitudes of \( \tilde{h}(n) \) are smaller than \( 1/\varepsilon \), then these small
coefficients will be replaced by zeros in high probability [11]. Here, it is worth noting that $\mu_{\text{iss}}(n)$ is a variable step-size

$$
\mu_{\text{iss}}(n) = \frac{\mu_{\text{iss}}(n)}{\|x_n\|^2 + c_m^2(n)}, \quad (10)
$$

which depends on three factors: initial step-size $\mu_{\text{iss}}$, input signal $x_n$ and update iterative error $c_m(n)$. Since $\mu_{\text{iss}}$ is given initial steps-size and $x_n$ is random scaling input signal, hence, $\mu_{\text{iss}}$ in Eq. (10) can also be rewritten as

$$
\mu_{\text{iss}}(n) = \frac{\mu_{\text{iss}}}{\|x_n\|^2 + c_m^2(n) + 1}, \quad (11)
$$

which is a variable step-size (VSS) which is adaptive change as square sensing error $c_m^2(n)$, smaller error incurs the smaller step-size to ensure the stability of the gradient descend while larger error yields larger step-size to accelerate the convergence speed of this algorithm [12].

![Fig. 3 Sparse constraint strength comparison using different reweights.](image)

**Input:** $X$, $y$, $\mu_{\text{iss}}$, $\varepsilon$ and $\lambda$

**Output:** $\hat{h}$

**Initialize:**

$h(0) \leftarrow 0$ ;

$n \leftarrow 1$ ;

**While** $\|\hat{h}(n+1) - \hat{h}(n)\| < \zeta$ or $n > n_{\text{max}}$ **Do**

Determine $x_n$ and $y_n$ with $m \leftarrow \text{mod}(n, M) + 1$ ;

Calculate error $c_m(n)$ as $c_m(n) \leftarrow y_n - x_n^* \hat{h}(n)$ ;

Update $\hat{h}(n+1)$ with update Eq. (9);

$n \leftarrow n + 1$

**End**

**Algorithm 1.** Realization of ASS using RZA-NLMF.

According to the update equation in (9), our proposed ASS method can be concluded in **Algorithm 1**, where $\zeta > 0$ is a given error tolerance and $n_{\text{max}}$ is a given maximum iteration number. The CRLB of the proposed ASS can be obtained as

$$
\text{CRLB}\{\hat{h}_{\text{iss}}\} = E\left\{\|\hat{h}_{\text{iss}} - h\|^2\right\} = \frac{5\mu_{\text{iss}}}{9\mu_{\text{iss}}^2\sigma_s^2\sigma_s^2 - 2\sigma_s^2} - \frac{27\mu_{\text{iss}}^2\sigma_s^2 - 6\mu_{\text{iss}}^2}{\rho^2 NK}
$$

About detailed derivation of the CRLB, interested authors are suggested to refer [13].

**IV. COMPUTER SIMULATIONS**

In this section, the proposed ASS approach using RZA-NLMF algorithm is evaluated. For achieving average performance, 1000 independent Monte-Carlo runs are adopted. For easy evaluating the effectiveness of the proposed approach, signal representation domain $D$ is assumed as a random identity matrix $I_{N \times N}$ and unknown signal $s$ is set as sparse directly. Sensing matrix is equivalent to random measurement matrix, i.e., $X = W$. For ensuring $X$ satisfies the RIP, $W$ is set as random Gaussian matrix [5]. Then, sparse coefficient vector $h$ equals to $s$. The detail simulation parameters are listed in Tab. 1. Notice that each nonzero coefficient of $h$ follows random Gaussian distribution as $CN(0, \sigma_s^2)$ and their positions are randomly allocated within the signal length of $h$ which is subject to $E\{|h|_2^2\} = 1$, where $E\{|\cdot|\}$ denotes the expectation operator. The output signal-to-noise ratio (SNR) is defined as $20\log(E_s/\sigma_s^2)$, where $E_s = 1$ is the unit transmission power. All of the step sizes and regularization parameters are listed in Tab. 1. The estimation performance is evaluated by average mean square error (MSE) which is defined by

$$
\text{Average MSE}\{\hat{h}(n)\} := E\left\{\|h - \hat{h}(n)\|^2\right\}, \quad (13)
$$

where $h$ and $\hat{h}(n)$ are the actual channel vector and its $n$-th iterative adaptive channel estimator, respectively. According to our previous work [8], regularization parameter for RZA-NLMF is set as $\lambda = 5 \times 10^{-5}$ so that it can exploit signal sparsity robustly. Since the RZA-NLMF-based ASS method depends highly on the reweighted factor $\varepsilon$, hence, we first select the reasonable factor $\varepsilon$ by virtual of Monte Carlo. Later, we compare the proposed method with two typical NSS ones, i.e., BPDN [6] and OMP [7].

| Parameters | Values |
|------------|--------|
| Signal length | $N = 40$ |
| Measurement length | $M = 20$ |
| Sensing matrix | Random Gaussian distribution |
| No. of nonzero coefficients | $K \in \{2, 6, 10\}$ |
| Distribution of nonzero coefficients | Random Gaussian |
| Signal-to-noise ratio (SNR) | (0dB, 12dB) |
| Initial step-size: $\mu_{\text{iss}}$ | 1.5 |
| Regularization parameter: $\lambda$ | $5 \times 10^{-4}$ |
| Re-weighted factor: $\varepsilon$ | 2000 |
A. Reweighted factor selection

Since the RZA-NLMF algorithm depends highly on reweighted factor. Hence, selection of the robust reweighted factor for different noise environments and different signal sparsity is typical important step for the RZA-NLMF algorithm.

It is well known that $\ell_0$-norm normalized least mean fourth (L0-NLMF) for CS can achieve optimal solution but it is a NP hard problem in practical applications such as noise environment [2]. One can find that RZA-NLMF reduces to L0-NLMF when the reweighted factor approaches to infinity. Due to the noise interference, we should select the suitable reweighted factor which can not only exploit signal sparsity but also can mitigate noise interference effectively. Hence, reweighted factor of the RZA-NLMF is selected empirically. By means of Monte Carlo method, performance curves of the proposed ASS method with different reweighted factors $\varepsilon \in \{2,20,200,2000,20000\}$ with respect to different number of nonzero coefficients $K \in \{2,6,10\}$ and different SNR regimes (5dB and 10dB) are depicted in Figs. 4–7.

Under the simulation setup considered, RZA-NLMF using $\varepsilon = 2000$ can achieve robust performance in different cases as shown in Figs. 4–7. From the four figures, one can find that sparser signal requires larger reweighted factor but no more than 20000 in this system. This is concise with the fact that stronger sparse penalty not only exploits more sparse information but also mitigates more noise interference.
B. Performance comparisons with NSS

Two experiments of ASS are verified in performance comparisons with conventional NSS methods (e.g., BPDN [6] and OMP [7]). In the first experiment, ASS method is evaluated in the case of SNR = 10 dB as shown in Fig. 8. On the one hand, according to this figure, we can find that the proposed ASS method using RZA-NLMF algorithm achieves much lower MSE performance than NSS methods and even if its CRLB.

![Fig. 8 Performance comparisons versus signal sparsity.](image)

The existing big performance gap between ASS and NSS is that ASS using RZA-NLMF not only exploits the signal sparsity but also mitigates the noise interference using high-order error statistics for adaptive error updating. On the other hand, we can also find that ASS depends on the signal sparseness. That is to say, for sparser signal, ASS can exploit more signal structure information as for prior information and vice versa. In the second experiment, number of nonzero coefficients is fixed as $K=2$ as shown in Fig. 9. It is easy to find that our proposed ASS is much better than conventional NSS as the SNR increasing.

![Fig. 9 Performance comparisons versus SNR.](image)

V. CONCLUSIONS AND FUTURE WORK

In this paper, we proposed an ASS method using RZA-NLMF algorithm for dealing with the CS problems. First, we decided the reweighted factor and regularization parameter for the proposed algorithm by virtual of Monte Carlo method. Later, based on update equation of the RZA-NLMF, CRLB of ASS was also derived based on the random independent assumptions. Finally, several representative simulations have been given to show that proposed method achieves much better MSE performance than NSS with respect to different signal sparsity, especially in the case of low SNR regime.
