QUASI-LINEAR STOKES PHENOMENON FOR THE PAINLEVÉ FIRST EQUATION

A. A. KAPAEV

ABSTRACT. Using the Riemann-Hilbert approach, the Ψ-function corresponding to the solution of the first Painlevé equation \( y_{xx} = 6y^2 + x \) with the asymptotic behavior \( y \sim \pm \sqrt{-x/6} \) as \( |x| \to \infty \) is constructed. The exponentially small jump in the dominant solution and the coefficient asymptotics in the power-like expansion to the latter are found.

1. INTRODUCTION

The Painlevé first equation \( (P_1) \)
\[
y_{xx} = 6y^2 + x,
\]
is the simplest of the six classical equations of Painlevé–Gambier \[2\] and can be derived from any other Painlevé equation using certain scaling reductions \[3\]. The recent interest to this equation is due to its significant role in various physical models.

For instance, equation \( P_1 \) describes certain solutions to KdV and Bussinesq equations \[4, 5\], bifurcations in some non-integrable nonlinear models \[6\], continuous limits in matrix models of quantum gravity \[7, 8, 9, 10\]: Ψ-function associated with \( P_1 \) appears in \( n \)-large asymptotics of semi-classical orthogonal and bi-orthogonal polynomials \[11, 12\] and thus becomes a primary object in the problem of Laplacian growth \[13\].

In context of the string theory, “physical” solutions of \( P_1 \) are distinguished from “non-physical” ones by the monotonic asymptotic behavior as \( x \to -\infty \) \[7, 8, 10, 14, 15\]. There are two kinds of such monotonic boundary conditions, i.e. \( y(x) \simeq \pm \sqrt{-x/6} \). Using elementary perturbation analysis, the solution \( y(x) = -\sqrt{-x/6} + \mathcal{O}(x^{-2}) \) is unique as being a background to a 2-parametric family of oscillating solutions. Solutions approaching a positive branch of the square root as \( x \to -\infty \), i.e. \( y(x) \simeq \sqrt{-x/6}, \) form a 1-parametric family parameterized by an amplitude of an exponentially small perturbation to a power-like dominant solution. These solutions have the asymptotic expansion \( y(x) = \sqrt{-x/6} \sum_{k=0}^{\infty} a_k (-x)^{-5k/2} + \mathcal{O}(x^{-\infty}) \), whose coefficients \( a_k \), admit a combinatorial interpretation \[16, 17\].

In the problem of Laplacian growth without surface tension (Hele-Shaw problem, quantum Hall effect etc.), the shape of a growing droplet is described using certain Ψ-function, see \[13\]. If the droplet develops a cusp singularity, this Ψ-function can be approximated by a Ψ-function associated to the first Painlevé transcendent, \[13\]. Certain “physical” asymptotic conditions imposed on this Ψ-function determine the relevant Stokes multipliers \( s_k \). In turn, these \( s_k \) pinch out the monotonic as \( x \to -\infty \) Painlevé function \( y(x) \simeq \sqrt{-x/6} \).
Equation $P_1$ has unexpectedly rich asymptotic properties in the complex $x$-plane. P. Boutroux [19] has shown that, generically, asymptotics of the Painlevé first transcendent as $|x| \to \infty$ is described by the modulated Weierstraß elliptic function whose module is a transcendent function of $\text{arg } x$. Furthermore, the module function is such that the elliptic asymptotic ansatz degenerates along the directions $\text{arg } x = \pi + \frac{2\pi}{5}n$, $n = 0, \pm 1, \pm 2$. P. Boutroux called the corresponding trigonometric expansions “truncated” solutions. Their 1- and 0-parameter reductions, if they admit analytic continuation into one or two neighboring sectors of the complex $x$-plane, were called by Boutroux “bi-truncated” and “tri-truncated” solutions. All bi- and tri-truncated solutions have the algebraic leading order behavior, $y(x) \sim \pm \sqrt{-x/6}$, perturbed by exponential terms.

We call a discontinuity in the asymptotic form of an analytic function the Stokes phenomenon. In the case of $P_1$, a jump in the phase shift of a modulated elliptic ansatz across the rays $\text{arg } x = \pi + \frac{2\pi}{5}n$ is called the nonlinear Stokes phenomenon. For bi- and tri-truncated solutions, a jump in the exponentially small perturbation of a dominant solution resembles the well known Stokes phenomenon in the linear theory and thus is called the quasi-linear Stokes phenomenon.

In [20, 21, 22], equation $P_1$ was studied further using classical tools like the perturbation approach and the method of nonlinear integral equations. Mainly, these articles discuss the behavior of the Painlevé transcendent on the real line. The recent paper [23] adopts the same approach carefully studying the behavior of the tri-truncated solution on the negative part of the real line.

In [24, 25], the multiple scale analysis was applied to $P_1$ (and $P_2$) to find a precise form of the phase shift in the elliptic asymptotic ansatz within complex sectors between the indicated rays. In [14, 15], the Whitham averaging method was used to describe the elliptic tail of the monotonic at $-\infty$ solution of $P_1$.

The isomonodromy deformation approach to Painlevé equations, see [26, 27, 28], was applied to equation $P_1$ in [29, 30, 31]. In this way, the asymptotics of the Painlevé functions is expressed in terms of the Stokes multipliers of an associated linear system. Then the equation of a monodromy surface yields connection formulas for the asymptotic parameters along different directions of the complex $x$-plane. A complete description of the nonlinear Stokes phenomenon in $P_1$ is given in [39]. A heuristic description of the quasi-linear Stokes phenomenon in $P_1$ can be found in [29].

Using the Borel transform technique and some assumptions on the analytic properties of the relevant Borel transforms, as well as the isomonodromy deformation approach based on the so-called exact WKB analysis, Y. Takei [32] has re-derived the latter result (look for more discussion in [33]).

In the present paper, we construct the $\Psi$-function associated with the monotonic as $|x| \to \infty$ solution of $P_1$ and rigorously describe the relevant quasi-linear Stokes phenomenon. Our main tool is the Riemann-Hilbert (RH) problem. We observe that the jump graph for our RH problem can be decomposed into a disjoint union of two branches, one of which is responsible for the background $\sqrt{-x/6}$ while another one produces the exponentially small perturbation of the dominant solution (look [33] for similar observation in $P_2$ case). Using the steepest descent approach of Deift and Zhou [34], we prove the unique solubility of this problem and compute the asymptotics of the Painlevé transcendent.
Applying a rotational symmetry, we prove the existence of five solutions, \( y_{4n}(x) \), \( n = 0, \pm 1, \pm 2 \), asymptotic to \( \sqrt{e^{-i\pi x}/6} \) as \( |x| \to \infty \) in the respective overlapping sectors \( \arg x \in (-\frac{\pi}{3} - \frac{4\pi}{5}n, \frac{\pi}{3} - \frac{4\pi}{5}n) \), see (2.69), (2.71), and find the exponentially small differences \( y_{4(n-1)}(x) - y_{4n}(x), n = 0, \pm 1, \pm 2 \), see (2.71). The latter constitute the quasi-linear Stokes phenomenon.

A collection of the functions \( y_{4n}(x) \), \( n = 0, \pm 1, \pm 2 \), forms a piece-wise meromorphic function \( \tilde{y}(x) \sim \sqrt{e^{-i\pi x}/6} \) as \( |x| \to \infty \). The moments of this function immediately yield the asymptotics as \( k \to \infty \) for the coefficients \( a_k \) (5.12) of the \( x \)-series expansion to the dominant solution (3.1). For the first time, the formula for the coefficient asymptotics was found in [32]. The authors of [23] studied the recurrence relations for the same coefficients by direct means and prove a similar asymptotic formula modulo a common factor (an advanced version of the direct approach to a generalized recurrence relation which contains one for \( P_1 \) as a special case can be found in [35]). The exact value of this common factor was announced in [23] with the reference to the method of [36] based on the Borel transform formula. In contrast, we do not use the Borel transform technique at any stage of our investigation.

The paper is organized as follows. In Section 2, we recall the Lax pair for \( P_1 \), formulate the relevant RH problem and solve it asymptotically. Using the approximate \( \Psi \)-function, we find the asymptotics of the bi- and tri-truncated Painlevé transcendents and of the relevant Hamiltonian functions. In Section 3, we find the coefficient asymptotics in the power-like expansion to the formal solution of \( P_1 \).

2. RIEMANN-HILBERT PROBLEM FOR P1

Introduce generators of \( su(2, \mathbb{C}) \), \( \sigma_3 = \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix} \), \( \sigma_+ = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \) and the Pauli matrices \( \sigma_1 = \sigma_+ + \sigma_- \) and \( \sigma_2 = -i\sigma_+ + i\sigma_- \) together and consider the system of matrix differential equations for \( \Psi \), see (3.11) (3.12).

\[
\begin{align*}
\frac{\partial \Psi}{\partial \lambda} \Psi^{-1} &= A(\lambda, x) = -z \sigma_3 + (2\lambda^2 + 2y\lambda + x + 2y^2) \sigma_+ + 2(\lambda - y) \sigma_- , \\
\frac{\partial \Psi}{\partial x} \Psi^{-1} &= U(\lambda, x) = (\lambda + 2y) \sigma_+ + \sigma_- .
\end{align*}
\]

Compatibility of (2.1a) and (2.1b) implies that the coefficients \( z \) and \( y \) depend on the deformation parameter \( x \) in accord with the nonlinear differential system

\[
\begin{align*}
y_x &= z , \\
z_x &= 6y^2 + x,
\end{align*}
\]

which is equivalent to the classical Painlevé first equation [1]. Following [23], see also [39], linear equation (2.1a) has the only one (irregular) singular point at infinity, and there exist solutions \( \Psi_k(\lambda) \) of (2.1) with the asymptotics

\[
\Psi_k(\lambda) = \lambda^{\frac{1}{\sqrt{2}}(\sigma_3 + \sigma_1)}(I - 3(\sigma_3 \lambda^{-1/2} + O(\lambda^{-1}))) e^{\theta(\lambda) \sigma_3} , \quad \theta(\lambda) = \frac{1}{2} \lambda^{5/2} + x\lambda^{1/2} ,
\]

as

\[
\lambda \to \infty, \quad \lambda \in \Omega_k = \{ \lambda \in \mathbb{C} : \arg \lambda \in \left( \frac{2\pi}{5} (k - \frac{1}{2}), \frac{2\pi}{5} (k + \frac{1}{2}) \right) \} , \quad k \in \mathbb{Z} .
\]

Solutions \( \Psi_k(\lambda) \), \( k \in \mathbb{Z} \), are called the canonical solutions, while sectors \( \Omega_k \) are called the canonical sectors. Canonical solutions \( \Psi_k(\lambda) \) are uniquely determined by
and solve both equations (2.1). They differ from each other in constant right matrix multipliers $S_k$ called the Stokes matrices,

$$
(2.5) \quad \Psi_{k+1}(\lambda) = \Psi_k(\lambda)S_k, \quad S_{2k-1} = \begin{pmatrix} 1 & s_{2k-1} \\ 0 & 1 \end{pmatrix}, \quad S_{2k} = \begin{pmatrix} 1 & 0 \\ s_{2k} & 0 \end{pmatrix}.
$$

Observing that all solutions of (2.1a) are entire functions, thus

$$
(2.6) \quad \Psi_k(e^{2\pi i \lambda}) = \Psi_k(\lambda),
$$

and using the relation

$$
(2.7) \quad \Psi_{k+5}(e^{2\pi i \lambda}) = \Psi_k(\lambda)\hat{S}_1
$$

which follows from the definition of the canonical solutions and the asymptotics (2.9), we readily find the constraints for the Stokes matrices [29],

$$
(2.8) \quad S_{k+5} = \sigma_1 S_k \sigma_1, \quad S_1 S_2 S_3 S_4 S_5 = i \sigma_1,
$$
or, in the scalar form,

$$
(2.8) \quad s_{k+5} = s_k, \quad 1 + s_k s_{k+1} = -i s_{k+3}, \quad k \in \mathbb{Z}.
$$

Thus, generically, two of the Stokes multipliers $s_k, k \in \mathbb{Z}$, determine all others.

The inverse monodromy problem consists of reconstruction of $\Psi_k(\lambda)$ using the known values of the Stokes multipliers $s_k$. It can be equivalently formulated as a Riemann-Hilbert (RH) problem. With this aim, introduce the union of rays $\gamma = \rho \cup (\cup_{k=1}^5 \gamma_{k-3})$, where $\gamma_k = \{ \lambda \in \mathbb{C} : \arg \lambda = \frac{2\pi k}{5}, k = -2, -1, 0, 1, 2 \}$, and $\rho = \{ \lambda \in \mathbb{C} : \arg \lambda = \pi \}$, all oriented toward infinity. Denote the sectors between the rays $\rho$ and $\gamma_2$ by $\omega_2$, between $\gamma_{k-1}$ and $\gamma_k$, $k = -1, 0, 1, 2$, by $\omega_k$, and between $\gamma_2$ and $\rho$ by $\omega_3$. All the sectors $\omega_k$ are in one-to-one correspondence with the canonical sectors $\Omega_k$ (2.4), see Figure 1.

Let each of the sectors $\omega_k, k = -2, -1, \ldots, 3$, be a domain for a holomorphic $2 \times 2$ matrix function $\Psi_k(\lambda)$. Denote the collection of $\Psi_k(\lambda)$ by $\Psi(\lambda)$,

$$
(2.9) \quad \Psi(\lambda)|_{\lambda \in \omega_k} = \Psi_k(\lambda).
$$

Let $\Psi_+ (\lambda)$ and $\Psi_- (\lambda)$ be the limits of $\Psi(\lambda)$ on $\gamma$ to the left and to the right, respectively.

Let $\theta(\lambda) = \frac{1}{2} \lambda^{1/2} + x \lambda^{1/2}$ be defined on the complex $\lambda$-plane cut along the negative part of the real axis. The RH problem we talk about is the following one:

1. Find a piece-wise holomorphic $2 \times 2$ matrix function $\Psi(\lambda)$ such that

$$
(2.10) \lim_{\lambda \to \infty} \lambda^{1/2} \left( \frac{1}{\sqrt{2}} (\sigma_3 + \sigma_1) \lambda^{-\frac{1}{2} \sigma_3} \Psi(\lambda) e^{-\theta \sigma_3} - I \right) \text{ exists and is diagonal;}
$$

2. on the contour $\gamma$, the jump condition holds

$$
(2.11) \quad \Psi_+(\lambda) = \Psi_-(\lambda) S(\lambda),
$$

where the piece-wise constant matrix $S(\lambda)$ is given by equations:

$$
(2.12a) \quad S(\lambda)|_{\gamma_k} = S_k, \quad S_{2k-1} = I + s_{2k-1} \sigma_+ \quad S_{2k} = I + s_{2k} \sigma_-,
$$

$$
(2.12b) \quad S(\lambda)|_{\rho} = -i \sigma_1,
$$

with the constants $s_k$ satisfying the constraints (2.8);
Because \( \Psi(\lambda) \) satisfies the asymptotic condition

\[
Y(\lambda) := \frac{1}{\sqrt{2}} (\sigma_3 + \sigma_1) \lambda^{-\frac{1}{2}} \Psi(\lambda) e^{-\theta \sigma_3} = \\
= \left( 1 - \frac{2y}{\lambda^{3/2}} + \frac{2y^2}{2x} + \mathcal{O}(\lambda^{-3/2}) \right) + \frac{y}{\lambda^{1/2}} + \mathcal{O}(\lambda^{-3/2}) + \mathcal{O}(\lambda^{-3/2}), \quad \lambda \to \infty,
\]

where

\[
\mathcal{H} = \frac{1}{2} z^2 - 2y^3 - xy,
\]

the solution \( y(x) \) of the Painlevé equation can be found from the “residue” of \( Y(\lambda) \) at infinity,

\[
y = 2 \lim_{\lambda \to \infty} \lambda Y_{12}(\lambda) = 2 \lim_{\lambda \to \infty} \lambda Y_{21}(\lambda).
\]

**Remark 2.1.** It is easy to see that \( \mathcal{H} \) is nothing but the Hamiltonian for the Painlevé first equation with the canonical variables \( q = y \) and \( p = z \).

Equation (2.15) specifies the Painlevé transcendent as a function \( y = f(x, \{s_k\}) \) of the deformation parameter \( x \) and of the Stokes multipliers \( s_k \). Using the solution \( y = f(x, \{s_k\}) \) and the symmetries of the Stokes multipliers described in [29], we obtain further solutions of [P1]

\[
y = e^{i\frac{\pi}{n}} f(e^{i\frac{\pi}{n}} x, \{s_{k+2n}\}), \quad n \in \mathbb{Z},
\]

where the bar means the complex conjugation.
By technical reason, to find the asymptotics of \( y(x) \), we use below not \( Y(\lambda) \) but related auxiliary functions \( \chi(\lambda) \) and \( X(\lambda) \) with expansions \( (2.18) \) and \( (2.19) \), respectively. The latter involve differences \( y - \hat{y}(x) \) and \( \hat{y}(x) \) are known, which can be estimated using singular integral equations with contracting operators.

2.1. Asymptotic solution for \( s_0 = 0 \). Let us consider the RH problem above where \( s_0 = 0 \) assuming that \( |x| \to \infty \) within the sector \( \arg x \in [\frac{3\pi}{4}, \pi] \). Equations \( (2.12a) \) imply that \( \Psi(\lambda) \) has no jump across the ray \( \gamma_0 = \{ \lambda \in \mathbb{C} : \arg \lambda = 0 \} \). The constraints \( (2.8) \) reduce to the following system of equations,

\[
(2.17) \quad s_{-2} = s_2 = s_1 + s_1 = i.
\]

Our first step in the RH problem analysis consists of introduction an auxiliary \( g \)-function,

\[
(2.18) \quad g(\lambda) = \frac{2}{\sqrt{3}}(\lambda + 2\lambda_0)^{5/2} - 4\lambda_0(\lambda + 2\lambda_0)^{3/2}, \quad \lambda_0 = \sqrt{e^{-ix}x/6},
\]

defined on the complex \( \lambda \)-plane cut along the ray \((-\infty, -2\lambda_0]\). The asymptotics of \( g \)-function as \( \lambda \to \infty \) coincides with the canonical one,

\[
(2.19) \quad g(\lambda) = \frac{4}{\sqrt{3}}(\lambda - 2\lambda_0)^{5/2} - 4\lambda_0(\lambda - 2\lambda_0)^{3/2} + \mathcal{O}(\lambda^{-3/2}) = \frac{4}{\sqrt{3}}\lambda^{5/2} + x\lambda^{1/2} + \mathcal{O}(\lambda^{-1/2}).
\]

Let us formulate an equivalent RH problem for the piece-wise holomorphic function \( Z(\lambda) \),

\[
(2.20) \quad Z(\lambda) = Y(\lambda)e^{(\theta(y) - g(y))\sigma_3} = \frac{1}{\sqrt{2}}(\sigma_3 + \sigma_1)\lambda^{-4\sigma_3}\Psi(\lambda)e^{-g(\lambda)\sigma_3},
\]

\[
i) \quad Z(\lambda) \to I \quad \text{as} \quad \lambda \to \infty; \quad \lambda \in \gamma_k,
\]

\[
(2.21) \quad ii) \quad Z_+(\lambda) = Z_-(\lambda)G(\lambda), \quad G(\lambda) = e^{g\sigma_3}e^{-g\sigma_3}, \quad \lambda \in \gamma_k,
\]

\[
Z_+(\lambda) = \sigma_1Z_-(\lambda)\sigma_1, \quad \lambda \in \rho.
\]

If \( S(\lambda) = I + s\sigma_\pm \) then \( G(\lambda) = I + se^{\pm2\sigma_\pm} \). Our next goal is to transform the jump contour \( \gamma \) to the contour of the steepest descent for the matrix \( G(\lambda) - I \). We denote by \( \gamma_+ \) the level line \( \Im g(\lambda) = \text{const} \) passing through the stationary phase point \( \lambda = \lambda_0 = \sqrt{e^{-ix}x/6} \) and asymptotic to the rays \( \arg \lambda = \pm \frac{2\pi}{5} \). This is the steepest descent line for \( e^{2g} \). Let \( \gamma_+ = \cup_j \ell_1 \cup \sigma \) be the union of the level lines \( \ell_j \), \( j = 0, 1, 2 \), \( \Im g(\lambda) = \text{const} \), and \( \sigma \), \( \Re g(\lambda) = \text{const} \), all emanating from the critical point \( \lambda = -2\lambda_0 \). Among them, the level line \( \ell_1 \) approaching the ray \( \arg \lambda = \frac{2\pi}{5} \) (if \( \arg x = \pi \), the level line \( \ell_1 \) is the segment \([-2\lambda_0, \lambda_0]\)) is the steepest descent line for \( e^{2g} \), while the level lines \( \ell_0 \) and \( \ell_2 \) approaching the rays \( \arg \lambda = -\frac{2\pi}{5} \) and \( \arg \lambda = \frac{4\pi}{5} \), respectively, are the steepest descent lines for \( e^{-2g} \). The level line \( \sigma \), \( \Re g(\lambda) = \text{const} \), approaches the ray \( \arg \lambda = \pi \).

Since the Stokes matrix \( S_1 \) can be factorized,

\[
S_1 = \begin{pmatrix} 1 & s_1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & i - s_1 \\ 0 & 1 \end{pmatrix} = S_{-1}^{-1} \begin{pmatrix} 1 & i \\ 0 & 1 \end{pmatrix},
\]

it is convenient to consider the following equivalent RH problems for \( \Psi(\lambda) \):

for \( \arg x \in [\frac{3\pi}{4}, \pi] \), the jump contour is the union of \( \gamma_+ \) oriented from up to down and \( \gamma_- \) whose components are oriented toward infinity, see Figure 1. The jump
matrices are as follows:

\begin{align*}
\lambda \in \gamma_+ & : \quad S(\lambda) = S_- = \begin{pmatrix} 1 & s_{-1} \\ 0 & 1 \end{pmatrix}, \\
\lambda \in \ell_1 & : \quad S(\lambda) = S_+ = \begin{pmatrix} 1 & i \\ 0 & 1 \end{pmatrix}, \\
\lambda \in \ell_0 \cup \ell_2 & : \quad S(\lambda) = S_- = \begin{pmatrix} 1 & 0 \\ i & 1 \end{pmatrix}, \\
\lambda \in \sigma & : \quad S(\lambda) = -i\sigma_1.
\end{align*}

(2.22)

Remark 2.2. The jump contour for the RH problem (2.22) is decomposed into the disjoint union of the line \(\gamma_+\) and the graph \(\gamma_-\), see Figure 2. For the boundary value \(\arg x = \pi - 0\), the level line \(\ell_1\) emanating from \(\lambda = -2\lambda_0\) passes through the stationary phase point \(\lambda = \lambda_0\) and partially merges with the upper half of the level line \(\gamma_+\). To construct the RH problem however, it is not necessary to transform the jump contour precisely to the steepest descent graph. It is enough to ensure that the jump matrices approach the unit matrix uniformly with respect to \(\lambda\) and fast enough as \(x \to \infty\) or \(\lambda \to \infty\).

As \(\arg x \in \left[\frac{3\pi}{2}, \pi\right]\), introduce the reduced RH problem \((s_0 = s_{-1} = 0)\) for the piece-wise holomorphic function \(\Phi(\lambda)\) discontinuous across \(\gamma_-\) only:

\begin{align*}
i) \quad & \lim_{\lambda \to \infty} \lambda^{1/2} \left( \frac{1}{\sqrt{2}} (\sigma_3 + \sigma_1) \lambda^{-\frac{1}{2}\sigma_3} \Phi(\lambda) e^{-\theta\sigma_3} - I \right) \text{ is diagonal}, \\
ii) \quad & \Phi_+(\lambda) = \Phi_-(\lambda)S(\lambda), \quad \lambda \in \gamma_- = \bigcup_{j=0,1,2} \ell_j \cup \sigma.
\end{align*}

(2.23)

The jump matrix \(S(\lambda)\) here is defined in (2.22).
Theorem 2.1. If arg $x \in \left[\frac{3\pi}{4}, \pi\right]$ and $|x|$ is large enough, then there exists a unique solution of the RH problem (2.23). The Painlevé function $y_0(x)$ corresponding to $s_0 = s_1 = 0$ has the asymptotics $y_0(x) = \sqrt{e^{ix}x/6} + O(x^{-2})$ as $x \to \infty$ in the above sector.

Proof. Uniqueness. Since $\det S(\lambda) \equiv 1$, we have $\det \Phi_+ = \det \Phi_-$, and hence $\det \Phi(\lambda)$ is an entire function. Furthermore, because of normalization of $\Phi(\lambda)$ at infinity, $\det \Phi(\lambda) \equiv -1$. Let $\Phi$ and $\Phi$ be two solutions of (2.23). Taking into account the cyclic relation in (2.8) which implies the continuity of the RH problem for $\Phi(\lambda)$ at $\lambda = -2\lambda_0$, the “ratio” $\chi(\lambda) = \Phi(\lambda)\Phi^{-1}(\lambda)$ is an entire function of $\lambda$. Using the Liouville theorem and normalization of $\Phi$ and $\Phi$ at infinity, we find $\chi(\lambda) \equiv I$, i.e. $\Phi(\lambda) \equiv \Phi(\lambda)$.

Existence. Introduce an auxiliary function

\[ (2.24) \quad \hat{\Phi}_0(z) = \begin{pmatrix} v'_1(z) & v'_2(z) \\ v_1(z) & v_2(z) \end{pmatrix}, \]

where the prime means differentiation w.r.t. $z$ and

\[ (2.25) \quad v_1(z) = \sqrt{2\pi} e^{i\pi/6} \text{Ai}(e^{2i\pi/3} z), \quad v_2(z) = -\sqrt{2\pi} \text{Ai}(z), \]

with $\text{Ai}(z)$ standing for the classical Airy function which can be defined using the Taylor expansion \[40\text{-}41\].

\[ (2.26) \quad \text{Ai}(z) = \frac{1}{3^{2/3} \Gamma(\frac{2}{3})} \sum_{k=0}^{\infty} \frac{3^k \Gamma(k + \frac{1}{3}) z^{3k}}{\Gamma(\frac{2}{3})(3k)!} - \frac{1}{3^{1/3} \Gamma(\frac{1}{3})} \sum_{k=0}^{\infty} \frac{3^k \Gamma(k + \frac{2}{3}) z^{3k+1}}{\Gamma(\frac{2}{3})(3k+1)!}. \]

Asymptotics at infinity of this function and its derivative are as follows,

\[ (2.27) \quad \text{Ai}(z) = \frac{1}{2\sqrt{\pi}} z^{-1/4} e^{-\frac{2}{3} z^{3/2}} \left\{ \sum_{n=0}^{N} (-1)^n 3^{-2n} \frac{\Gamma(3n + \frac{1}{3})}{\Gamma(\frac{2}{3})(2n)!} z^{-3n/2} + O(z^{-3(N+1)/2}) \right\}, \]

\[ \text{Ai}'(z) = \frac{1}{2\sqrt{\pi}} z^{1/4} e^{-\frac{2}{3} z^{3/2}} \left\{ \sum_{n=0}^{N} (-1)^n 3^{-2n} \frac{\Gamma(3n - \frac{1}{3})}{\Gamma(\frac{2}{3})(2n)!} z^{-3n/2} + O(z^{-3(N+1)/2}) \right\}, \]

as $z \to \infty$, arg $z \in (-\pi, \pi)$.

It is worth to note that the function $\hat{\Phi}_0(z)$ satisfies the linear differential equation

\[ (2.28) \quad \frac{d\hat{\Phi}_0}{dz} = \{ z\sigma_+ + \sigma_- \} \hat{\Phi}_0. \]

Using the properties of the Airy functions, we find that the products

\[ (2.29) \quad \Phi_1(z) = \hat{\Phi}_0(z) S_-, \quad \Phi_2(z) = \hat{\Phi}_1(z) S_+, \quad \Phi_3(z) = \hat{\Phi}_2(z) S_-, \]

$S_{\pm} = I + i\sigma_{\pm}$, have the asymptotic expansion

\[ (2.30) \quad \hat{\Phi}_k(z) = z^{\frac{k}{2} \sigma_3} \frac{1}{\sqrt{2}} (\sigma_3 + \sigma_1) V_\infty(z) e^{\frac{2}{3} z^{3/2} \sigma_3}, \]

as $|z| \to \infty$, arg $z \in \left(-\pi + \frac{2\pi}{3} k, 2\pi + \frac{2\pi}{3} k\right)$, where

\[ (2.31) \quad V_\infty(z) = I - \sum_{n=1}^{\infty} 3^{-2n} \frac{\Gamma(3n - \frac{1}{3})}{2\Gamma(\frac{2}{3})(2n)!} z^{-3n/2} \left\{ \frac{1}{6n} \begin{pmatrix} 1 & (-1)^n 6n \\ \end{pmatrix} \right\}. \]
Let $\hat{\gamma}_- = \hat{\sigma} \cup j=0,1,2 \hat{\ell}_j$ be the union of the rays $\hat{\ell}_j = \{z \in \mathbb{C}: \arg z = \frac{2\pi}{3}(j-1)\}$, $j = 0,1,2$, and $\hat{\sigma} = \{z \in \mathbb{C}: \arg z = \pi\}$ all oriented toward infinity. This graph divides the complex $z$-plane into four regions: $\hat{\omega}_0$ which is the sector between $\hat{\sigma}$ and $\hat{\ell}_0$, the sectors $\hat{\omega}_k$, $k = 1,2$, between the rays $\hat{\ell}_{k-1}$ and $\hat{\ell}_k$, and the sector $\hat{\omega}_3$ between the rays $\hat{\ell}_2$ and $\hat{\sigma}$.

![Diagram of the model RH problem graph.](image)

Figure 3. The model RH problem graph.

Define a piece-wise holomorphic function $\hat{\Phi}(z)$,

$$
\hat{\Phi}(z) \bigg|_{z \in \hat{\omega}_k} = \hat{\Phi}_k(z).
$$

By construction, this function solves the following RH problem, see Figure 3:

$$
\begin{align*}
\hat{\Phi} & : \hat{\gamma}_- : \hat{\Phi}_+ (z) = \hat{\Phi}_- (z) \hat{S}(z), \\
\hat{S} & : \hat{\ell}_1 : \hat{S}(z) = S_+, \quad \hat{S} : \hat{\ell}_0 \cup \hat{\ell}_2 : \hat{S}(z) = S_- .
\end{align*}
$$

Therefore the function $\hat{\Phi}(z)$ has precisely the jump properties of the function $\Phi(\lambda)$. To find $\Phi(\lambda)$ with the correct asymptotic behavior at infinity, let us use the mapping

$$
\frac{2}{3} z^{3/2} = g(\lambda) = \frac{4}{9}(\lambda + 2\lambda_0)^{5/2} - 4\lambda_0(\lambda + 2\lambda_0)^{3/2}, \quad \text{or}
\end{align*}
$$

$$
\lambda(\lambda + 2\lambda_0) = (-6\lambda_0)^{2/3}(\lambda + 2\lambda_0)(1 - \frac{1}{5\lambda_0}(\lambda + 2\lambda_0))^{2/3}, \quad \lambda_0 = \sqrt{e^{-i\pi x/6}}.
$$

Within the disk $|\lambda + 2\lambda_0| < R < 3|\lambda_0| = |\frac{2}{3} x|^{1/2}$, the mapping (2.35) yields a holomorphic change of the independent variable. Introduce a piece-wise holomorphic
function $\hat{\Phi}(\lambda)$,

$$
\hat{\Phi}(\lambda) = \begin{cases} 
B(\lambda)\hat{\Phi}(z(\lambda)), & |\lambda + 2\lambda_0| < R, \\
(\lambda + 2\lambda_0)^{\frac{1}{2}\sigma_3} \frac{1}{\sqrt{2}} (\sigma_3 + \sigma_1) e^{g(\lambda)\sigma_3}, & |\lambda + 2\lambda_0| > R,
\end{cases}
$$

(2.36)

where $(\lambda + 2\lambda_0)^{1/4}$ is defined on the plane cut along the level line $\sigma$ asymptotic to the ray $\arg \lambda = \pi$. Note that $B(\lambda)$ is holomorphic in the interior of the above disk $|\lambda + 2\lambda_0| \leq R < 3|\lambda_0|$ and thus does not affect the jump properties of $\hat{\Phi}(z(\lambda))$. We look for the solution of the RH problem (2.36) in the form of the product

$$
\Phi(\lambda) = (I + (4\lambda_0^3 - 3\ell_+\sigma_+))\chi(\lambda)\hat{\Phi}(\lambda).
$$

(2.37)

Consider the RH problem for the correction function $\chi(\lambda)$. By construction, it is a piece-wise holomorphic function discontinuous across the clockwise oriented circle $L$ of the radius $R$ centered at $-2\lambda_0$ and across the part of $\gamma_-$ located outside the above circle (in fact, $\chi(\lambda)$ is continuous across $\sigma$, see (2.39) below). The latter is divided by $\gamma_-$ in four arcs: $L_0$ between $\sigma$ and $\ell_0$, $L_k$, $k = 1, 2$, between $\ell_{k-1}$ and $\ell_k$, and $L_3$ between $\ell_2$ and $\sigma$, see Figure 4. To simplify our notations, let us put

$$
\tilde{\lambda} = \lambda + 2\lambda_0.
$$

(2.38)

Then the RH problem for $\chi(\lambda)$ is as follows:

1. $\chi(\lambda) \to I$, \hspace{1cm} $\lambda \to \infty$;
2. $\chi^+(\lambda) = \chi^-(\lambda)G(\lambda)$, \hspace{0.5cm} $\lambda \in \ell$, \hspace{0.5cm} where
   - $\lambda \in \ell_1$, $|\tilde{\lambda}| > R$: \hspace{0.5cm} $G(\lambda) = I + \frac{i}{2} e^{2\sigma} (\sigma_3 - \tilde{\lambda}^{1/2}\sigma_+ + \tilde{\lambda}^{-1/2}\sigma_-)$,
   - $\lambda \in \ell_0 \cup \ell_2$, $|\tilde{\lambda}| > R$: \hspace{0.5cm} $G(\lambda) = I + \frac{i}{2} e^{-2\sigma} (\sigma_3 + \tilde{\lambda}^{1/2}\sigma_+ - \tilde{\lambda}^{-1/2}\sigma_-)$,
   - $\lambda \in \sigma$, $|\tilde{\lambda}| > R$: \hspace{0.5cm} $G(\lambda) = I$,

(2.39)

Taking into account the equations (2.34), it is easy to check the continuity of the RH problem at the node points. Observing that, on the circle $|\tilde{\lambda}| = R = c|x|^{1/2}$, $0 < c < \sqrt{3}/2$, we have $z(\lambda) = \mathcal{O}(|x|^{5/6})$ is large, we immediately see that

$$
\|G(\lambda) - I\| \leq c|x|^{1/2} e^{-(2/3)|x|^{1/2} |\tilde{\lambda}|^{1/2}}, \hspace{0.5cm} \lambda \in \ell_k, \hspace{0.5cm} k = 0, 1, 2, \hspace{0.5cm} |\tilde{\lambda}| \geq R,
$$

(2.40)

where the precise value of the positive constant $c$ is not important for us. Taking into account that, by the above reason, on the circle $|\tilde{\lambda}| = R$, we may use for $\Phi_k$ its asymptotics (2.30), the jump matrix $G(\lambda)$ has the asymptotic expansion

$$
G(\lambda) - I = - \infty \sum_{n=1} \frac{3^{-2n}}{2 \Gamma(\frac{1}{2})(2n)!} \left( \frac{(1 + (-1)^n)(1 + 6n)}{2} \frac{(1 - (-1)^n)(1 + 6n)\tilde{\lambda}^{1/2}}{2} \right) z^{2n} \left( \frac{(1 + (-1)^n)(1 + 6n)}{2} \frac{(1 - (-1)^n)(1 + 6n)\tilde{\lambda}^{-1/2}}{2} \right),
$$

$$
z = (-6\lambda_0)^{2/3}(1 - \frac{\tilde{\lambda}}{5\lambda_0})^{2/3}, \hspace{0.5cm} \tilde{\lambda} = \lambda + 2\lambda_0, \hspace{0.5cm} |\tilde{\lambda}| = R.
$$

(2.41)

Therefore, we have the estimate

$$
\|G(\lambda) - I\| \leq cR^{-2} = c'|x|^{-1},
$$

(2.42)
where the precise value of the positive constants $c, c'$ is not important for us.

Now, the solubility of the RH problem (2.39) and therefore of (2.23) for large enough $|x|$ is straightforward. Indeed, consider the equivalent system of the non-homogeneous singular integral equations for the limiting value $\chi^+(\lambda)$, i.e.

$$\chi^+(\lambda) = I - \frac{1}{2\pi i} \int_{\ell} \frac{\chi^+(\zeta)(G^{-1}(\zeta) - I)}{\zeta - \lambda_+} d\zeta,$$

or, in the symbolic form, $\chi^+ = I + K\chi^+$. Here $\lambda_+$ means the left limit of $\lambda$ on $\ell$ (recall, that the circle $|\tilde{\lambda}| = R$ is clock-wise oriented), and $K$ is the composition of the operator of the right multiplication in $G^{-1}(\lambda) - I$ and of the Cauchy operator $C_+$. An equivalent singular integral equation for $\psi^+ := \chi^+ - I$ differs from (2.43) in the inhomogeneous term only,

$$\psi^+ = KI + K\psi^+.$$

Consider the integral equation (2.44) in the space $L^2(\ell)$. Since $G^{-1}(\lambda) - I$ is small in $L^2(\ell)$ for large enough $|x|$, and $C_+$ is bounded in $L^2(\ell)$, then $\|K\|_{L^2(\ell)} \leq c|x|^{-1/2}$ with some positive constant $c$, thus $K$ is contracting and $I - K$ is invertible in $L^2(\ell)$ for large enough $|x|$. Because $KI \in L^2(\ell)$, equation (2.44) for $\psi^+$ is solvable in $L^2(\ell)$, and the solution $\chi(\lambda)$ of the RH problem (2.39) is determined by $\psi^+(\lambda)$ using the equation $\chi^+ = I + KI + K\psi^+$.

Let us find the asymptotics of the Painlevé function. Using (2.44) and definition of $\tilde{\Phi}(\lambda)$ (2.36), the asymptotics of $\chi(\lambda)$ as $\lambda \to \infty$ in terms of $y$ and $3\kappa$ is as follows,

$$\chi(\lambda) = I + \frac{1}{2\lambda}(y - \lambda_0 - (4\lambda_0^3 - 3\kappa)^2)\sigma_3 + \frac{1}{\lambda}(4\lambda_0^3 - 3\kappa)\sigma_+ + \left(\frac{O(\lambda^{-3/2})}{O(\lambda^{-3/2})}, \frac{O(\lambda^{-3/2})}{O(\lambda^{-3/2})}\right).$$

On the other hand, in accord with the said above, the function $\chi^+$ is given by the converging iterative series, $\chi^+ = \sum_{n=0}^{\infty} K^n I$. To compute the term $K^n I$, we observe that the contribution of the infinite branches $\ell_k$ is exponentially small in $x$. 

**Figure 4.** A RH problem graph for the correction function $\chi(\lambda)$. 

Quasi-linear Stokes phenomenon for P1

11
due to estimate (2.44). Using the expansion (2.41), we reduce the evaluation of the integral along the circle $|\lambda| = R$ to the residue theorem. Omitting this elementary computation, we present the final result: For large enough $|x|$, arg $x \in [\frac{3\pi}{5}, \pi]$, the asymptotics of $\chi(\lambda)$ as $\lambda \to \infty$ is given by

$$
\chi(\lambda) = I + \left( \frac{O(\lambda^{-4})}{O(\lambda^{-1})} \right).
$$

Comparing entries $\chi_{21}(\lambda)$ in (2.40) and (2.41), we see that the Hamiltonian function $H = H_0(x)$ corresponding to the Stokes multipliers $s_0 = s_{-1} = 0$ is given by

$$
H = H_0(x) = 4 \lambda_0^2 + O(\lambda_0^{-1}) = 4(-x/6)^{3/2} + O(x^{-1}).
$$

Next comparing entries $\chi_{11}(\lambda)$ in (2.40) and (2.41), and using (2.47), we find the asymptotics of the Painlevé function $y = y_0(x)$,

$$
y = y_0(x) = \lambda_0 + O(\lambda_0^{-1}) = \sqrt{-x/6} + O(x^{-2}).
$$

Recall that $\lambda_0 = (e^{-i\pi}x/6)^{1/2}$ where the main branch of the root is taken. \hfill \Box

Let us go to the case of the nontrivial $s_{-1}$ described by the RH problem (2.22). We look for the solution $\Psi(\lambda)$ in the form of the product

$$
\Psi(\lambda) = (I - (H - H_0)\sigma_+)X(\lambda)\Phi(\lambda),
$$

where $\Phi(\lambda)$ is the solution of the reduced RH problem (2.23) and $H_0$ (2.24) is the Hamiltonian function (2.14) corresponding to the Painlevé transcendent $y_0(x)$ (2.48). Using (2.48), we find the asymptotics of $X(\lambda)$ as $\lambda \to \infty$,

$$
X(\lambda) = (I + (H - H_0)\sigma_+)\Phi^{-1} =
$$

$$
= I + \frac{1}{2\lambda}(y - y_0 - (H - H_0)^2)\sigma_3 - \frac{1}{\lambda}(H - H_0)\sigma_- + \left( \frac{O(\lambda^{-3/2})}{O(\lambda^{-2})} \right).
$$

Thus we arrive at the RH problem for the correction function $X(\lambda)$ on the steepest descent line $\gamma_+$,

$$
i) \quad X(\lambda) \to I, \quad \lambda \to \infty,
$$

$$
ii) \quad X(+\lambda) = X(-\lambda)S(\lambda), \quad \lambda \in \gamma_+,
$$

$$
S(\lambda) = \Phi(\lambda)S_{-1}\Phi^{-1}(\lambda).
$$

Note, $\Phi(\lambda)$ is continuous across $\gamma_+$ and therefore holomorphic in some neighborhood of $\gamma_+$ as arg $x \in [\frac{3\pi}{5}, \pi]$, $|x|$ is large enough.

The jump matrix on $\gamma_+$ can be estimated as follows,

$$
||S(\lambda) - I|| \leq c|s_{-1}|e^{-2^{21/4}g^{1/4}|x|^{5/4}}c(\arg x - \pi)\epsilon e^{-2^{21/4}g^{1/4}|x|^{5/4}|\lambda - \lambda_0|^2}.
$$

Here $c$ is some positive constant whose precise value is not important for us, and $\lambda_0 = (e^{-i\pi}x/6)^{1/2}$ is the stationary phase point for $\exp(g(\lambda))$, see (2.12). Estimate (2.02) yields the estimate for the norm of the singular integral operator $K$ in the equivalent system of singular integral equations, $X_- = I + KX_-$,

$$
||K||_{L_2(\gamma_+)} \leq c' |s_{-1}|e^{-2^{21/4}g^{1/4}|x|^{5/4}c(\arg x - \pi)}, \quad c' > 0.
$$

If $|x|$ is large enough and arg $x \in [\frac{3\pi}{5} + \epsilon, \pi]$, $\epsilon > 0$, then the operator $K$ is contracting and the system $X_- = I + KX_-$ is solvable by iterations in $L_2(\gamma_+)$, i.e. $X_- = $
\[ \sum_{n=0}^{\infty} K^n X_. \] However, to incorporate the oscillating direction \( \arg x = \frac{3\pi}{5} \) in the general scheme, we use some more refined procedure.

**Theorem 2.2.** If \( s_0 = 0, \arg x \in [\frac{3\pi}{5}, \pi] \) and \( |x| \) is large enough, then there exists a unique solution of the RH problem (2.10) – (2.12). The corresponding Painlevé function has the asymptotics

\[ (2.54) \quad y(x) = y_0(x) + \frac{s-1}{\sqrt{\pi}} 2^{-11/8} 3^{-1/8} (e^{-i\pi} x)^{-1/8} e^{-\frac{1}{8} 2^{11/4} 3^{1/4} (e^{-i\pi} x)^{5/4}} (1 + \mathcal{O}(x^{-3/8})), \]

where \( y_0(x) \sim \sqrt{e^{-i\pi} x / 6} \) is the solution of the Painlevé equation for \( s_0 = s_- = 0, s_1 = s_2 = s_3 = s_4 = i \).

**Proof.** It is enough to prove the solubility of the RH problem (2.10).

Using for \( \Psi(\lambda) \) the expressions (2.47) with (2.46) and the estimate (2.40) together, we find the asymptotics of the jump matrix \( \mathcal{G}(\lambda) \),

\[ (2.55) \quad \mathcal{G}(\lambda) = I + \frac{1}{2} s_1 e^{2g} \begin{pmatrix} 1 + \mathcal{O}(\lambda_0^{-2} \lambda^{-1/2}) & -\lambda^{1/2} + \mathcal{O}(\lambda_0^{-2}) \\ \lambda^{-1/2} + \mathcal{O}(\lambda_0^{-2} \lambda^{-1}) & 1 \end{pmatrix}, \]

\[ \lambda \in \gamma_+, \quad \lambda = \lambda + 2\lambda_0. \]

Consider the following model RH problem,

\[ (2.56) \quad i) \quad P(\lambda) \to I, \quad \lambda \to \infty, \]

\[ ii) \quad P_+ (\lambda) = P_- (\lambda) \mathcal{G}(\lambda), \quad \lambda \in \gamma_+, \]

\[ \hat{\mathcal{G}}(\lambda) = I + \frac{1}{2} s_1 e^{2g} \begin{pmatrix} 1 & (3\lambda_0)^{-1/2} \\ (3\lambda_0)^{-1/2} & -1 \end{pmatrix}. \]

This problem is solvable by the following quadrature,

\[ (2.57) \quad P(\lambda) = I + \frac{1}{2} s_1 e^{2g} \int_{\gamma_+} \frac{e^{\frac{1}{2} s_1 e^{2g}}}{(\zeta - \lambda)(3\lambda_0)^{-1/2}} \begin{pmatrix} 1 & (3\lambda_0)^{-1/2} \\ (3\lambda_0)^{-1/2} & -1 \end{pmatrix}. \]

We look for the solution \( X(\lambda) \) of the RH problem (2.56) in the form of the product,

\[ (2.58) \quad X(\lambda) = Q(\lambda) P(\lambda). \]

The correction function \( Q(\lambda) \) satisfies the RH problem

\[ (2.59) \quad i) \quad Q(\lambda) \to I, \quad \lambda \to \infty, \]

\[ ii) \quad W_+ (\lambda) = Q_- (\lambda) W(\lambda), \quad \lambda \in \gamma_+, \]

\[ W(\lambda) = P_-(\lambda) \mathcal{G}(\lambda)^{-1} P^{-1}_-(\lambda). \]

Using (2.59) – (2.57), we find the estimate for the jump matrix \( W(\lambda) \) on \( \gamma_+ \),

\[ (2.60) \quad W(\lambda) = I + \mathcal{O}(s_1 e^{2g} (\lambda - \lambda_0)_{\lambda_0}^{-1/2}), \quad \lambda \in \gamma_+. \]

Our next steps are similar to presented in the proof of Theorem 2.1. Consider the system of the singular integral equations for \( Q_+ (\lambda) \) equivalent to the RH problem (2.44), \( Q_+ = I + 2Q_+ \). Here the singular integral operator \( \mathcal{K} \) is the superposition of the multiplication operator in \( W - I \) and of the Cauchy operator \( C_+ \). Because the Cauchy operator is bounded in \( L_2(\gamma_+) \), the singular integral operator \( \mathcal{K} \) for large enough \( |x| \), \( \arg x \in [\frac{3\pi}{5}, \pi] \), satisfies the estimate

\[ (2.61) \quad \|\mathcal{K}\|_{L_2(\gamma_+)} \leq c s_{-1} |x|^{-1/2} e^{-\frac{1}{2} 2^{11/4} 3^{1/4} |x|^{5/4} \cos(\frac{1}{4}(\arg x - \pi))}, \]
with some positive constant $c$ whose precise value is not important for us. Thus equation $\zeta_+ = KI + K\zeta_+$ for the difference $\zeta_+ := Q_+ - I$ is solvable by iterations in the space $L_2(\gamma_+)$ for large enough $|x|$. Solution of the RH problem (2.50) is given by the integral $Q = I + KI + K\zeta_+$. This implies the asymptotics of $Q(\lambda)$ as $\lambda \to \infty$,

$$
(2.62) \quad Q(\lambda) = I + \frac{1}{2\pi i} \int_{\gamma_+} \left( I + O(KI(\zeta)) \right) \left( I - W^{-1}(\zeta) \right) \frac{d\zeta}{\zeta - \lambda} = I + O(\lambda^{-1}x^{-1/2} \exp(\frac{1}{2}2^{11/4}3^{1/4} \text{Re}(e^{-i\pi} x^{5/4}))).
$$

Now let us find the asymptotics of the Painlevé function $y(x)$. Using (2.62), (2.63) and the estimate (2.66), we find

$$
(2.63) \quad X(\lambda) = I + \frac{8 - 1}{\lambda \sqrt{\pi}} 2^{-19/8} 3^{-1/2} (e^{-i\pi} x^{-1/2}) 2^{11/4} 3^{1/4} (e^{-i\pi} x^{5/4}) (I + O(x^{-3/8})) \times
$$

$$
\times \left( 2^{1/4} 3^{-1/4} (e^{-i\pi} x)^{1/4} - 2^{1/4} 3^{1/4} (e^{-i\pi} x)^{1/4} - 1 \right).
$$

Comparing (2.63) and (2.50), we conclude that the Hamiltonian function for $s_0 = 0$ is as follows,

$$
(2.64) \quad \mathcal{H}(x) = \mathcal{H}_0(x) - \frac{8 - 1}{\sqrt{\pi}} 2^{-17/8} 3^{-3/8} (e^{-i\pi} x)^{-3/8} e^{-\frac{1}{2}2^{11/4} 3^{1/4} (e^{-i\pi} x)^{5/4}} (1 + O(x^{-1/8})),
$$

while the Painlevé function is given by

$$
(2.65) \quad y(x) = y_0(x) + \frac{8 - 1}{\sqrt{\pi}} 2^{-11/8} 3^{-1/8} (e^{-i\pi} x)^{-1/8} e^{-\frac{1}{2}2^{11/4} 3^{1/4} (e^{-i\pi} x)^{5/4}} (1 + O(x^{-3/8})),
$$

where $\mathcal{H}_0(x)$ and $y_0(x)$ are the Hamiltonian and the Painlevé functions, respectively, corresponding to $s_0 = s_{-1} = 0$.

2.2. Other degenerate Painlevé functions. Applying the symmetry (2.10a) to the solution (2.64) and changing the argument of $x$ in $2\pi$, we obtain

**Theorem 2.3.** If $s_0 = 0$ and $|x| \to \infty$, $\arg x \in [\pi, \frac{3\pi}{2}]$, then the asymptotics of the Painlevé first transcendent is given by

$$
(2.66) \quad y(x) = y_1(x) - \frac{8 - 1}{\sqrt{\pi}} 2^{-11/8} 3^{-1/8} (e^{-i\pi} x)^{-1/8} e^{-\frac{1}{2}2^{11/4} 3^{1/4} (e^{-i\pi} x)^{5/4}} (1 + O(x^{-3/8})),
$$

where $y_1(x) \sim \sqrt{e^{-i\pi} x/6}$ is the solution of the Painlevé equation for $s_0 = s_1 = 0$, $s_{-1} = s_{-2} = 1$.

The solutions $y_0(x)$ and $y_1(x) = y_0(e^{2\pi i} x)$ are meromorphic functions of $x \in \mathbb{C}$ and thus can be continued beyond the sectors indicated in Theorems 2.2 and 2.3. To find the asymptotics of $y_1(x)$ in the interior of the sector $\arg x \in [\frac{3\pi}{2}, \pi]$, we apply (2.66). Similarly, we find the asymptotics of the solution $y_0(x)$ in the interior of the sector $\arg x \in [\pi, \frac{3\pi}{2}]$ using (2.66). Either expression implies

**Corollary 2.4.** If $|x| \to \infty$, $\arg x \in [\frac{3\pi}{2}, \pi]$, then

$$
(2.67) \quad y_1(x) - y_0(x) = \frac{i}{\sqrt{\pi}} 2^{-11/8} 3^{-1/8} (e^{-i\pi} x)^{-1/8} e^{-\frac{1}{2}2^{11/4} 3^{1/4} (e^{-i\pi} x)^{5/4}} (1 + O(x^{-3/8})).
$$
Applying symmetries (2.16) to \( y_k(x) \), \( k = 0, 1 \), we find the solutions \( y_k(x) \) corresponding to the Stokes multipliers \( s_k = s_{k-1} = 0 \),

\[
y_{2n}(x) = e^{i\frac{4\pi}{5}n} y_0(e^{i\frac{4\pi}{5}n} x) \quad \text{for} \quad s_{2n} = s_{2n-1} = 0,
\]
\[y_{2n+1}(x) = e^{i\frac{4\pi}{5}n} y_1(e^{i\frac{4\pi}{5}n} x) \quad \text{for} \quad s_{2n+1} = s_{2n} = 0.
\]

Since there is one-to-one correspondence between the points of the monodromy (2.68) implies that \( y_2 \) and \( s_k \) will uniquely determine the values of all the Stokes multipliers \( s_k \).

Using Theorems 2.2 and 2.3, we find that

\[
y_{4n}(x) = y_{4n+5}(x) = \sqrt{e^{-i\pi \frac{x}{6}} + O(x^{-2})},
\]
\[|x| \to \infty, \quad \text{arg} x \in [\frac{\pi}{6} - \frac{4\pi}{5} n, \pi - \frac{4\pi}{5} n],
\]
\[
y_{4n-2}(x) = y_{4n+3}(x) = -\sqrt{e^{-i\pi \frac{x}{6}} + O(x^{-2})},
\]
\[|x| \to \infty, \quad \text{arg} x \in [\frac{\pi}{6} - \frac{4\pi}{5} n, \frac{7\pi}{6} - \frac{4\pi}{5} n].
\]

The symmetry (2.16) with the definition (2.68) applied to (2.67) yields

**Corollary 2.5.** If \( |x| \to \infty \) and \( \arg x \in [\frac{3\pi}{5} - \frac{2\pi}{5} n, \frac{2\pi}{5} - \frac{2\pi}{5} n] \), then

\[
y_{2n+1}(x) - y_{2n}(x) = e^{i\frac{4\pi}{5} + i\frac{4\pi}{5} n} \sqrt{\pi} 2^{-11/8} 3^{-1/8} (e^{-i\pi \frac{x}{6}} - 1/8 e^{-\frac{i\pi}{5} x})^{-1/8} e^{-\frac{i\pi}{5} x} x^{3/4} \times (1 + O(x^{-3/8})),
\]

On the one hand, equations (2.67), (2.71) constitute the quasi-linear Stokes phenomenon for the Painlevé first equation. On the other hand, these equations give the asymptotic description of the degenerate Painlevé functions beyond the sectors in (2.69) and (2.70). Observing that the difference (2.71) is exponentially small in the interior of the indicated sector, we conclude that the asymptotics (2.69) and (2.70) as \( |x| \to \infty \) continue to wider open sectors,

\[
y_{4n}(x) = \sqrt{e^{-i\pi \frac{x}{6}} + O(x^{-2})}, \quad \text{arg} x \in (\epsilon - \frac{7\pi}{6} - \frac{4\pi}{5} n, \frac{7\pi}{6} - \frac{4\pi}{5} n - \epsilon),
\]
\[
y_{4n-2}(x) = -\sqrt{e^{-i\pi \frac{x}{6}} + O(x^{-2})}, \quad \text{arg} x \in (\epsilon + \frac{\pi}{6} - \frac{4\pi}{5} n, \frac{\pi}{6} - \frac{4\pi}{5} n - \epsilon),
\]

where \( \epsilon > 0 \) is an arbitrary small constant.

**Remark 2.3.** The solutions \( y_n(x) \) (2.68) corresponding to the trivial values of two Stokes multipliers \( s_n = s_{n-1} = 0 \) are the most degenerate among the Painlevé transcendent since they behave algebraically in four of five sectors \( \arg x \in (-\frac{\pi}{5} + \frac{2\pi}{5} k, \frac{\pi}{5} + \frac{2\pi}{5} k) \), \( k = 0, \pm 1, \pm 2 \), see (2.72) (2.73). Nevertheless, these solutions are transcendental, since their asymptotics as \( |x| \to \infty \) within the remaining fifth sector involves the elliptic function of Weierstrass, look for more details in [30]. Moreover, the fact that the asymptotics of \( y_n(x) \) is not elliptic in four sectors uniquely determines the values of all the Stokes multipliers \( s_k \). Thus the asymptotics (2.72), (2.73) uniquely determine the degenerate solutions \( y_n(x) \).

**Remark 2.4.** The asymptotics of less degenerate solutions corresponding to \( s_n = 0 \) and \( s_{n+1} + s_{n-1} = i \) can be found applying the symmetries (2.16) to equations (2.69) and (2.70).
3. COEFFICIENT ASYMPTOTICS

Using the steepest descent approach, cf. [42], we can show the existence of the asymptotic expansion of \( y_n(x) \), \( n \in \mathbb{Z} \), in the negative degrees of \( x^{1/2} \). Further elementary investigation of the recursion relation for the coefficients of the series allows us to claim that the asymptotic expansion for \( y_n(x) \) in (2.72), (2.70) has the following form:

\[
(3.1) \quad y_j(x) = \sigma \left(-\frac{x}{6}\right)^{1/2} \sum_{k=0}^{\infty} a_k \sigma^k (-x)^{-5k/2} + \mathcal{O}(x^{-\infty}) = \\
= \sigma \left(-\frac{x}{6}\right)^{1/2} \sum_{k=0}^{\infty} a_{2k} (-x)^{-5k} + \frac{1}{\sqrt{6}} (-x)^{-2} \sum_{k=0}^{\infty} a_{2k+1} (-x)^{-5k} + \mathcal{O}(x^{-\infty}), \quad \sigma^2 = 1,
\]

where coefficients \( a_k \) are determined uniquely by the recurrence relation

\[
(3.2) \quad a_0 = 1, \quad a_{k+1} = \frac{25k^2-1}{8\sqrt{6}} a_k - \frac{1}{2} \sum_{m=1}^{k} a_m a_{k+1-m}.
\]

Several initial terms of the expansion are given by

\[
(3.3) \quad y_j(x) = \sigma \sqrt{-2x/6} \left\{ 1 + \frac{499}{868} - \frac{4412401}{1709648000} + \frac{245229441961}{4006642962400} + \mathcal{O}(x^{-20}) \right\} - \\
\quad - \frac{1}{48x^2} \left\{ 1 - \frac{1225}{492} + \frac{7350925}{401520^2} - \frac{7759635184525}{3538944248000} + \mathcal{O}(x^{-20}) \right\}.
\]

Our next goal is to determine the asymptotics of the coefficients \( a_k \) in (3.1) as \( k \to \infty \). With this purpose, let us construct a sectorial analytic function \( \hat{y}(t) \),

\[
(3.4) \quad \arg t \in \left[-\frac{2\pi}{6}(n+1), -\frac{2\pi}{6}n\right]: \quad \hat{y}(t) = y_{4n}(e^{i\pi t^2}), \quad n = -2, -1, 0, 1, 2.
\]

The function \( \hat{y}(t) \) has a finite number of poles all contained in a circle \( |t| < \rho \) and is characterized by the uniform asymptotic expansion near infinity,

\[
(3.5) \quad \hat{y}(t) = \frac{t}{\sqrt{6}} \sum_{k=0}^{\infty} a_k t^{-5k} + \mathcal{O}(t^{-\infty}).
\]

Let \( y^{(N)}(t) \) be a partial sum

\[
(3.6) \quad y^{(N)}(t) = \frac{t}{\sqrt{6}} \sum_{k=0}^{N-1} a_k t^{-5k},
\]

and \( v^{(N)}(t) \) be a product

\[
(3.7) \quad v^{(N)}(t) = t^{5N-2} \sqrt{6} (\hat{y}(t) - y^{(N)}(t)) = t^{-1} \sum_{k=0}^{\infty} a_{k+N} t^{-5k} + \mathcal{O}(t^{-\infty}).
\]

Because \( t^{5N-2} y^{(N)}(t) \) is polynomial, the integral of \( v^{(N)}(t) \) along the counter-clockwise oriented circle of the radius \( |t| = \rho \) satisfies the estimate

\[
(3.8) \quad \left| \int_{|t|=\rho} v^{(N)}(t) \, dt \right| \leq \rho^{5N-2} \sqrt{6} \int_{|t|=\rho} |\hat{y}(t)| \, dt \leq \sqrt{6} 2\pi\rho^{5N-1} \max_{|t|=\rho} |\hat{y}(t)| = C \rho^{5N}
\]

with some positive constant \( C \) whose precise value is not important for us.
On the other hand, inflating the sectorial arcs of the circle $|t| = \rho$, we find that
\begin{equation}
(3.9) \quad \oint_{|t|=\rho} v^{(N)}(t) \, dt = \oint_{|t|=R} v^{(N)}(t) \, dt + \sum_{n=-2}^{2} \int_{(\rho,R)} e^{i2\pi n(t)} \left( v^{(N)}_{+}(t) - v^{(N)}_{-}(t) \right) \, dt.
\end{equation}
Because $v^{(N)}(t) = t^{-1}a_N + O(t^{-6})$, the first of the integrals in the r.h.s. of (3.9) is computed as follows:
\begin{equation}
(3.10) \quad \oint_{|t|=R} v^{(N)}(t) \, dt = 2\pi ia_N + O(R^{-5}).
\end{equation}
Remaining integrals in (3.9) are computed using definitions (3.3)–(3.4) and (3.5) with the identification $y_{-4}(x) = y_1(x)$ and the formula (2.17) together,
\begin{equation}
(3.11) \quad \sum_{n=-2}^{2} \int_{(\rho,R)} e^{i2\pi n(t)} \left( v^{(N)}_{+}(t) - v^{(N)}_{-}(t) \right) \, dt = 5\sqrt{6} \int_{(\rho,R)} t^{5N-2} \left( y_{-4}(e^{i\pi t^2}) - y_{0}(e^{i\pi t^2}) \right) \, dt =
\frac{5\sqrt{6}}{\sqrt{\pi}} 2^{-11/8} 3^{-1/8} \int_{(\rho,R)} t^{5N-\frac{5}{2}} e^{-\frac{1}{8} t^{2}} (1 + O(t^{-3/4})) \, dt =
\frac{2i\sqrt{6}}{\sqrt{3}\sqrt{\pi}} \left( \frac{1}{5} 2^{11/4} 3^{1/4} \right)^{-2N} \Gamma(2N - \frac{1}{2}) (1 + O(N^{-3/10}) + O(\rho^{5N-\frac{5}{2}})) +
\frac{O(e^{-\frac{1}{8}} 2^{11/4} 3^{1/4} R^{5/2} \rho^{5N-\frac{5}{2}})}.\end{equation}
Thus, letting $R = \infty$, we find the asymptotics of the coefficient $a_N$ in (3.1) as $N \to \infty$,
\begin{equation}
(3.12) \quad a_N = -\frac{\sqrt{6}}{\sqrt{3} \pi^{3/2}} \left( \frac{1}{5} 2^{11/4} 3^{1/4} \right)^{-2N} \Gamma(2N - \frac{1}{2}) (1 + O(N^{-3/10})) + O(\rho^{5N}), \quad N \to \infty.
\end{equation}

**Remark 3.1.** The presented asymptotic formula shows a remarkable accuracy: neglecting in (3.12) error terms, we find an approximation to $a_N$ with the relative error not exceeding 2% for $N = 4$ and 1% for $N = 7$. Furthermore, for the initial set of $N = 1, 2, \ldots, 7$, the relative error decreases approximately as $N^{-1}$ which is significantly better than estimated.
