Abstract

We propose an alternative scheme to generate the W state via optical state truncation using quantum scissors. In particular, these states may be generated through three-mode optical state truncation in a Kerr nonlinear coupler. The more general three-qubit state may also be produced if the system is driven by external classical fields.

A counterintuitive property of quantum mechanics, well known as entanglement, plays an important role in many of the most interesting applications of quantum mechanics in the development of quantum computation and quantum information [1]. It is also the main point of the debate in foundation issues and interpretation of quantum mechanics. Entanglement involving bipartite systems such as Bell states has been well understood [2] while entanglement of multipartite systems is still undergoing intense research [3]. There are two different classes of genuine tripartite entanglement, the Greenberger–Horne–Zeilinger (GHZ) class and the W class [4, 5]. These two states cannot be converted to each other by local operation and classical communication (LOCC) with a nonzero success probability. The first one, the Greenberger–Horne–Zeilinger (GHZ) state can be read as [6]

\[ |\text{GHZ}\rangle = \frac{1}{\sqrt{2}} (|000\rangle + |111\rangle), \]

while the W state may be expressed as [4]

\[ |W\rangle = \frac{1}{\sqrt{3}} (|001\rangle + |010\rangle + |100\rangle). \]

The W state is not a maximal entangled state, but it has the highest robustness against the loss of one qubit [4]. Fundamentally, differences between the violations of local realism exhibited by the GHZ and W states are illustrated by Cabello by considering a different set
of Bell inequalities [7]. Several applications exploiting W states have been proposed, such as quantum teleportation [8] and quantum secure communication [9]. Many papers also study the use of W states for the optimal universal cloning machine [10].

With regard to the useful applications of the W entangled state, it follows that preparation and generation of the state are becoming increasingly important. Zeilinger et al proposed a scheme using third-order nonlinearity for a path-entangled photon [11]. Cavity quantum electrodynamics can also be used to produce three entangled states [12, 13]. Yamamoto et al proposed an experimentally feasible scheme for preparing a polarization-entangled W state [14]. Preparation of the W state by using linear optical elements has been proposed by Xiang et al [15]. Experimental observation of the three-photon polarization-entangled W state has been discussed by Eibl et al [3].

In this paper, we propose a scheme for generation of the three-qubit entangled W state by nonlinear optical state truncation. In addition, by applying an external classical field this scheme can also generate a more general three-qubit state.

The method of optical state truncation using quantum scissors was first proposed by Pegg et al [16] to truncate a single-mode coherent state of light, which is the quantum mechanical analogue of a free classical single-mode electromagnetic field, involving superposition of a vacuum state and single-photon state. The states generated by optical state truncation are highly non-classical so that they are very useful for optical qubit generation. It has also been modified extensively to generate the superposition of a vacuum, one-photon and two-photon states by employing the projection principle [17]. Babichev et al [18] using the non-local single-photon state as the Einstein–Podolsky–Rosen pair have done the initial experimental test for quantum scissors. The resulted states were examined by the homodyne measurement technique, and it was also confirmed that the quality of truncation was well above the classical limit. Another experimental test has also been performed by Resch et al [19]. In earlier studies, the development and generalization of quantum scissors for optical state truncation are based on linear optical elements and restricted to single-mode optical truncation. Villas-Bôas et al [20] proposed quantum scissors by projection synthesis to get the teleported state of zero- and one-photon running-wave states. A proposal for practical realization was also analysed by using more realistic description for apparatus, for example, the detectors and single-photon source [21].

Quantum state truncation can also be performed in nonlinear systems involving the Kerr media. Leoński and Tanaś [22] proposed a scheme that can be considered as nonlinear quantum scissors in which a one-photon state can be obtained in a periodically kicked cavity by applying a sequence of classical light pulses and filled with nonlinear Kerr media. A model of nonlinear coupler excited by a single-mode coherent field and filled with Kerr media was investigated, and properties of such a system are much desired from the point of view of the physical properties of nonlinear couplers [23]. There the evolution of the system, starting from the vacuum state, leads to Bell-like states generation. It does mean that the system produces maximally entangled states (MES) and has interesting results applicable to the development of quantum information theory. Here, we generalize the system proposed in [23] to three-mode optical state truncation in a Kerr nonlinear coupler to generate three-qubit entangled W states.

The system proposed here can be illustrated by constructing three nonlinear oscillators coupled to each other and each oscillator can be driven optionally by an external classical field with linear excitation and constant amplitude. We will see that the existence of external coupling generates all of the bases instead of only three bases responsible for entangled W states. This physical model can be implemented by developing the model proposed by Leoński and Miranowicz [23] into three ring cavities filled with Kerr media as depicted in figure 1.
Mathematically, the proposed system Hamiltonian, as a sum of nonlinear Hamiltonians for each oscillator $\hat{H}_i (i = a, b, c)$ and interaction Hamiltonian $\hat{H}_{in}$, can be written as

$$\hat{H} = \frac{\chi_a}{2} \hat{a}^\dagger \hat{a}^\dagger \hat{a} \hat{a} + \frac{\chi_b}{2} \hat{b}^\dagger \hat{b}^\dagger \hat{b} \hat{b} + \frac{\chi_c}{2} \hat{c}^\dagger \hat{c}^\dagger \hat{c} \hat{c} + \epsilon \hat{a}^\dagger \hat{b}^\dagger + \epsilon^* \hat{a} \hat{b} + \epsilon^* \hat{a}^\dagger \hat{c}^\dagger + \epsilon \hat{a} \hat{c} + \epsilon^* \hat{b}^\dagger \hat{c} + \epsilon \hat{b} \hat{c} + \epsilon^* \hat{b} \hat{c}^\dagger. \quad (3)$$

Here $\chi_i (i = a, b, c)$ are Kerr nonlinearity constants related to higher order susceptibility of the nonlinear media. $a, b$ and $c$ are bosonic annihilation operators acting on mode 1, 2 and 3, respectively, while $a^\dagger, b^\dagger$ and $c^\dagger$ are corresponding bosonic creation operators. $\epsilon$ is a parameter describing the strength of coupling between oscillators. We consider $\epsilon$ as a real parameter for simplicity. It is necessary here to note that our model can be considered as an ideal model by neglecting damping processes. It then could be assumed that a very high-$Q$ cavity which can preserve the whole radiation field located inside practically is needed [23, 24]. Since experimental realizations of high-$Q$ cavities have been reported [25], we can consider that our proposal is feasible to be realized.

Evolution of the system, by neglecting the damping process, can be written in the Fock representation of a time-dependent wavefunction as

$$|\Phi(t)\rangle = \sum_{n,m,l=0}^{n,m,l=\infty} c_{nml} |n \rangle \otimes |m \rangle \otimes |l \rangle = \sum_{n,m,l=0}^{n,m,l=\infty} c_{nml} |n, m, l \rangle. \quad (4)$$

The amplitude, $c_{nml}$, is a complex probability amplitude of finding the system discussed in the $n$-photon, $m$-photon and $l$-photon states for the mode $a, b,$ and $c$ respectively. A set of the equations of motion for the amplitudes in the time domain can be obtained via the Schr"{o}dinger equation involving the Hamiltonian and the wavefunction above. For convenience, we take $\hbar$ as unity. It follows that

$$i \frac{d}{dt} c_{nml} = \frac{\chi_a}{2} c_{nml} m (n - 1) + \frac{\chi_b}{2} c_{nml} m (m - 1) + \frac{\chi_c}{2} c_{nml} l (l - 1)$$

$$+ \epsilon c_{n-1,m+1,l} \sqrt{n} \sqrt{m} + 1 + \epsilon^* c_{n+1,m-1,l} \sqrt{n} + 1 + \epsilon c_{n-1,m,l+1} \sqrt{m} \sqrt{l} + 1 + \epsilon^* c_{n+1,m,l-1} \sqrt{m} \sqrt{l} + 1. \quad (5)$$

The coupling parameters assumed here are weak compared to nonlinearity constants so that the transition of the state evolved can be treated as a resonant case. It leads to a situation
where dynamics of the system are in closed form and some subspaces of the state have a very small probability that can be neglected. For instance, taking \(n = 0, m = 0, l = 0\) to \(n = 2, m = 2, l = 2\) in equation (3) one can see that the amplitudes of the state higher than 2 are oscillating rapidly. Analogous to the rotating wave approximation (RWA), the influence of the probability amplitude for \(n, m, l \geq 2\) can be neglected. Hence, we get the truncated wavefunction as

\[
|\Psi_{\text{cut}}(t)\rangle = c_{000}|000\rangle + c_{001}|001\rangle + c_{010}|010\rangle + c_{011}|011\rangle + c_{100}|100\rangle + c_{101}|101\rangle + c_{110}|110\rangle + c_{111}|111\rangle.
\]  

Amplitudes can be obtained by solving the coupled equations below, and we assume that the initial state is \(|001\rangle\):

\[
\begin{align*}
\frac{d}{dt} c_{000} &= 0, \\
\frac{d}{dt} c_{001} &= \epsilon c_{100} + \epsilon c_{010}, \\
\frac{d}{dt} c_{010} &= \epsilon c_{100} + \epsilon c_{001}, \\
\frac{d}{dt} c_{011} &= \epsilon c_{101} + \epsilon c_{110}, \\
\frac{d}{dt} c_{100} &= \epsilon c_{010} + \epsilon c_{001}, \\
\frac{d}{dt} c_{101} &= \epsilon c_{101} + \epsilon c_{011}, \\
\frac{d}{dt} c_{110} &= \epsilon c_{011} + \epsilon c_{101}, \\
\frac{d}{dt} c_{111} &= 0.
\end{align*}
\]  

Due to the symmetry of the system, we can reduce the coupled equations (7) above and get analytical solutions for the amplitudes simply as

\[
\begin{align*}
c_{001} &= \frac{1}{\sqrt{2}} [2 \exp(i\epsilon t) + \exp(-2i\epsilon t)], \\
c_{010} &= c_{100} = \frac{1}{\sqrt{2}} [- \exp(i\epsilon t) + \exp(-2i\epsilon t)], \\
c_{000} &= c_{011} = c_{110} = c_{101} = c_{111} = 0.
\end{align*}
\]  

With these, we can express (6) as

\[
|\Psi_{\text{W}}(t)\rangle = \frac{1}{\sqrt{2}} [2 \exp(i\epsilon t) + \exp(-2i\epsilon t)]|001\rangle + \frac{1}{\sqrt{2}} [- \exp(i\epsilon t) + \exp(-2i\epsilon t)]|010\rangle + |100\rangle.
\]  

To check whether it is reasonable to truncate the wavefunction, we need to perform calculations for the full, actual generated wavefunction. Following the method discussed in [26] for single-mode optical state truncation and extended in [23] for the two-mode case, the calculations for the actual generated wavefunction can be performed by constructing firstly the unitary evolution operator \(\hat{U}\) of the total Hamiltonian:

\[
\hat{U} = e^{-i\hat{H}t}.
\]  

Applying the operator \(\hat{U}\) to the assumed initial state, the generated wavefunction can be obtained from the relation

\[
|\Psi_{\text{gen}}(t)\rangle = \sum_{n, m, l = 0}^{\infty} c_{nml}|n, m, l\rangle = \hat{U}|000\rangle.
\]  

It is necessary to mention here that the calculation will have better results if we perform it in larger dimensional Fock bases for each subspace associated with every mode of the field. The actual generated state in this paper is calculated in an eight-dimensional Fock basis to generate 512 states in \(|\Psi_{\text{gen}}(t)\rangle\), i.e.,

\[
|\Psi_{\text{gen}}(t)\rangle = \sum_{n, m, l = 0}^{7} c_{nml}|n, m, l\rangle = c_{000}|000\rangle + c_{001}|001\rangle + \cdots + c_{777}|777\rangle.
\]
Generation of three-qubit entangled W state by nonlinear optical state truncation

Figure 2. Probabilities of the states $|001\rangle$ (broken line) and $|100\rangle$ (solid line). $\chi_i(t = a, b, c) = 30$ and $\epsilon = \pi/30$. The actual generated results are presented by cross marks.

Figure 2 shows exact agreement of the time evolution of probabilities of the three states involved between truncated and actual generated ones. We can see here that W states are produced by the system at time $t_n = \frac{\pi}{3\epsilon} \left( (n - \frac{1 + (-1)^n}{2}) + \frac{1}{2} (-1)^n \right)$ for $n = 1, 2, 3, \ldots$. Since the system is undriven by any external field the actual generated state with bases $|n, m, l\rangle$ is exactly unpopulated. As mentioned above, this scheme can also generate the more general three-qubit state if the system is coupled to external classical fields. This can be done by inserting the term

$$\hat{H}_{\text{ext}} = \hat{H}^{(a)}_{\text{ext}} + \hat{H}^{(b)}_{\text{ext}} + \hat{H}^{(c)}_{\text{ext}}$$

$$= \alpha \hat{a}^\dagger + \alpha^* \hat{a} + \beta \hat{b}^\dagger + \beta^* \hat{b} + \gamma \hat{c}^\dagger + \gamma^* \hat{c}$$

in the Hamiltonian (3). After some straightforward calculations, we give below the analytical results for complex amplitudes corresponding to three identical and real external pumpings such that $\alpha = \beta = \gamma = \epsilon$ with an assumed initial condition $|c_{000}(t = 0)|^2 = 1$:

$$c_{000} = e^{-2i\epsilon t} \left( \frac{\sqrt{7}}{7} i \sin \sqrt{7} \epsilon t + \frac{1}{2} \cos \sqrt{7} \epsilon t \right) + \frac{1}{2} \cos \sqrt{3} \epsilon t,$$

$$c_{001} = -\frac{\sqrt{7}}{14} (i \cos 2\epsilon t \sin \sqrt{7} \epsilon t + \sin 2\epsilon t \sin \sqrt{7} \epsilon t) - \frac{\sqrt{3}}{6} i \sin \sqrt{3} \epsilon t,$$

$$c_{010} = c_{100} = c_{001},$$

$$c_{011} = c_{101} = c_{110} = c_{001} + \frac{\sqrt{3}}{3} i \sin \sqrt{3} \epsilon t,$$

$$c_{111} = c_{000} - \cos \sqrt{3} \epsilon t.$$  

In conclusion, it is proposed that a three-mode nonlinear coupler may generate the W state as well as the more general three-qubit state via optical state truncation. It is interesting to note that giant Kerr nonlinearities have been theoretically predicted [27] and first experimentally measured to be $\approx 10^6$ greater than those in the conventional optical materials [28]. This in
turn supports the feasibility of our scheme experimentally. The present set-up may be a source of generation of entangled optical qubits from classical light, which is a remarkably simple quantum information problem.
