Abstract

Introduction ScFv(FRP5)-ETA is a recombinant antibody toxin with binding specificity for ErbB2 (HER2). It consists of an N-terminal single-chain antibody fragment (scFv), genetically linked to truncated Pseudomonas exotoxin A (ETA). Potent antitumoral activity of scFv(FRP5)-ETA against ErbB2-overexpressing tumor cells was previously demonstrated in vitro and in animal models. Here we report the first systemic application of scFv(FRP5)-ETA in human cancer patients.

Methods We have performed a phase I dose-finding study, with the objective to assess the maximum tolerated dose and the dose-limiting toxicity of intravenously injected scFv(FRP5)-ETA. Eighteen patients suffering from ErbB2-expressing metastatic breast cancers, prostate cancers, head and neck cancer, non small cell lung cancer, or transitional cell carcinoma were treated. Dose levels of 2, 4, 10, 12.5, and 20 µg/kg scFv(FRP5)-ETA were administered as five daily infusions each for two consecutive weeks.

Results No hematologic, renal, and/or cardiovascular toxicities were noted in any of the patients treated. However, transient elevation of liver enzymes was observed, and considered dose limiting, in one of six patients at the maximum tolerated dose of 12.5 µg/kg, and in two of three patients at 20 µg/kg. Fifteen minutes after injection, peak concentrations of more than 100 ng/ml scFv(FRP5)-ETA were obtained at a dose of 10 µg/kg, indicating that predicted therapeutic levels of the recombinant protein can be applied without inducing toxic side effects. Induction of antibodies against scFv(FRP5)-ETA was observed 8 days after initiation of therapy in 13 patients investigated, but only in five of these patients could neutralizing activity be detected. Two patients showed stable disease and in three patients clinical signs of activity in terms of signs and symptoms were observed (all treated at doses ≥ 10 µg/kg). Disease progression occurred in 11 of the patients.

Conclusion Our results demonstrate that systemic therapy with scFv(FRP5)-ETA can be safely administered up to a maximum tolerated dose of 12.5 µg/kg in patients with ErbB2-expressing tumors, justifying further clinical development.

Introduction Aberrant expression of the epidermal growth factor receptor or the closely related ErbB2 (HER2/neu) receptor tyrosine kinase has been implicated in the formation of various human malignancies [1,2], making these receptors interesting targets for directed anticancer therapeutics. Antibodies that block lig-
and binding or interfere with receptor function can directly inhibit the growth of cancer cells in addition to their potential to direct effector cells of the immune system to the tumor [3]. With the humanized mAb Herceptin™ (trastuzumab), an ErbB2-specific reagent for the treatment of breast carcinomas is in clinical use. Monotherapy with the antibody or combination with chemotherapy protocols resulted in increased clinical benefit for a significant proportion of patients with ErbB2-overexpressing metastatic breast cancers [4,5]. Nevertheless, responses could not be achieved in all patients with tumors expressing high ErbB2 levels, suggesting that in addition to enhanced expression of the target receptor, other factors such as limited recruitment of endogenous immune effector mechanisms or the presence of alternative signaling pathways in tumor cells can also influence treatment outcome.

In contrast to such unmodified antibodies, antibody toxins are not dependent on the inhibition of signaling or on the recruitment of complement or endogenous killer cells for antitumor activity, but they combine antibody-mediated recognition of tumor cells with specific delivery of a potent cytotoxic effector molecule [6-8]. These tailor-made targeting reagents might therefore represent a valuable alternative to unmodified mAbs, and could complement their use in the clinic. ScFv(FRP5)-ETA is a recombinant single-chain antibody toxin with binding specificity for ErbB2-overexpressing tumor cells [9,10]. The N-terminal portion of the bacterially expressed molecule is contributed by a single-chain antibody fragment (scFv) derived from heavy-chain and light-chain variable domains of murine mAb FRP5, which recognizes the extracellular domain of human ErbB2 [11]. ScFv(FRP5)-ETA harbors a truncated Pseudomonas aeruginosa exotoxin A (ETA, PE) fragment (amino acids 252–613 of mature exotoxin A) at the C-terminus, which is devoid of the toxin’s natural cell-binding domain [9]. Upon specific binding of the scFv domain to ErbB2 on the surface of tumor cells, the antibody toxin is internalized by receptor-mediated endocytosis, the enzymatic domain of the molecule is released into the cytoplasm and ADP ribosylates elongation factor 2, a critical component of the target cell’s translation machinery [12]. Toxin-mediated inactivation of elongation factor 2 causes the inhibition of protein synthesis and results in subsequent tumor cell death by apoptosis [13,14].

Efficacy of scFv(FRP5)-ETA in the treatment of ErbB2-overexpressing tumors has been established in numerous preclinical in vitro and in vivo studies. ScFv(FRP5)-ETA displayed potent antitumoral activity in vitro against a wide range of established and primary human tumor cells, including breast and ovarian carcinomas [9,14,15], squamous cell carcinomas [10,16] and prostate carcinomas [17]. In experimental animals, locally or systemically applied scFv(FRP5)-ETA effectively inhibited the in vivo growth of human tumor xenografts [9,10,14,16], and murine and rat tumor cells stably transfected with human c-erbB2 constructs [18,19]. Thereby, complete elimination of subcutaneously growing tumors [16] and prevention of metastasis formation by disseminated cancer cells [19] was observed in some models.

Potent antitumoral activity in animal models has also been described for antibody toxins derived from the ErbB2-specific antibody e23 [20,21]. In cancer patients, however, intravenous application of such an e23-based antibody toxin resulted in severe liver toxicity, and effective doses could not be reached [22]. In contrast, for the scFv(FRP5)-ETA molecule utilizing the different FRP5 antibody domain, we could previously show that local treatment of cutaneous lesions of ErbB2-overexpressing tumors by intratumoral injection of the scFv(FRP5)-ETA molecule was well tolerated, and resulted in shrinkage or complete regression of injected tumor nodules in the majority of patients [23].

Here we now report the first systemic application of scFv(FRP5)-ETA in a phase I dose-finding study in human cancer patients, with the objective to assess the maximum tolerated dose and the dose-limiting toxicity. Furthermore, we have obtained data concerning pharmacokinetic properties of scFv(FRP5)-ETA and its ability to induce a neutralizing antibody response.

**Patients and methods**

**Patients**

Patients eligible for treatment with scFv(FRP5)-ETA had to be 18 years of age or older, with ErbB2-overexpressing tumors confirmed by immunohistochemistry (DAKO-Hercep test 3+) or fluorescence in situ hybridization analysis, showing clinical, radiological, or serological evidence for a progression. Other eligibility criteria included at least one previous palliative systemic chemotherapy treatment and an absence of any standard treatment option. Patients with serious illness or medical conditions besides the diagnosis of cancer, a Karnofsky index <60%, and immunoreactivity against scFv(FRP5)-ETA were excluded from the study. See Table 1 for further details on patient characteristics. The study was conducted in compliance with the Helsinki Declaration [24]. The treatment protocol and consent form were approved by the regulatory authorities and institutional ethics committees. Informed consent was obtained from the patients before therapy.

**ErbB2-specific antibody toxin**

Recombinant scFv(FRP5)-ETA was produced as an experimental drug under Good Manufacturing Practice conditions and was kindly provided by Ciba Geigy AG (Basel, Switzerland). Bacterial expression and isolation of recombinant protein from inclusion bodies was carried out following a protocol adapted for large-scale production from the basic procedures described elsewhere [18]. Homogeneity of the material was analyzed by SDS-PAGE and Coomassie staining, and the identity of the purified protein was confirmed by immunoblot analysis and amino acid sequencing. The content of endotox-
ins (<10 EU/ml at 0.1 mg/ml protein), content of *Escherichia coli* proteins (<11 µg/ml) and content of DNA (<20 pg/ml) were determined following standard procedures (data not shown). The antibody toxin was supplied as a sterile solution at 0.3 mg/ml scFv(FRP5)-ETA in a phosphate buffer [23]. Aliquots of scFv(FRP5)-ETA solution were transferred to 2 ml vials under sterile conditions in the hospital pharmacy and were stored at -70°C. Upon thawing and subsequent storage at temperatures between 4°C and 8°C, scFv(FRP5)-ETA retained full bioactivity for a minimum of 6 days (IC₅₀ for ErbB2-expressing Renca-lacZ/ErbB2 cells, 5–6 ng/ml) [19,23]. For application, the required amount of antibody toxin was thawed and kept until use for a maximum of 5 days at temperatures between 4°C and 8°C.

### Treatment schedule and dose levels

Experiments in mice and rats demonstrated efficacy of daily intravenous injections of scFv(FRP5)-ETA for 10 days against localized and metastatic tumors [18,19,25]. Based on these data, the treatment schedule for the phase I clinical study was developed: patients received a total of 10 intravenous infusions of scFv(FRP5)-ETA on day 1, day 2, day 3, day 4, day 5, day 8, day 9, day 10, day 11, and day 12. ScFv(FRP5)-ETA was diluted in physiological Ringer solution to achieve a total injection volume of 50 ml. A test dose of 10 µg intravenously was given as a 15-min infusion on day 1. The remaining dose was administered 4 hours later as a 15-min infusion. The dose levels of scFv(FRP5)-ETA were 2, 4, 10, 12.5, or 20 µg/kg per treatment day. Patients received 8 mg dexamethasone, 50 mg

ranitidine, and 2 mg clemastine as a supportive treatment 30 min prior to scFv(FRP5)-ETA infusion to avoid anaphylactic reactions.

Tumor assessments
The modified Response Evaluation Criteria in Solid Tumors were used for objective tumor response assessment in this trial. Chest X-ray, abdominal ultrasound or computed tomography scan, specific measurement of an indicator lesion, bone scan, or bone X-ray in the case of hot spots in the bone scan were performed within 3 months before therapy and on day 29 after the onset of scFv(FRP5)-ETA therapy. To ensure comparability, every effort was made to use the same instrumental examination from baseline through follow-up.

Safety evaluation
The overall proportion of patients experiencing any toxicity was determined using the National Cancer Institute Common Toxicity Criteria, and the corresponding grading system was used to grade adverse events for recording in the case report form. For all adverse events not classified by National Cancer Institute Common Toxicity Criteria, the COSTART grading classification [26] was used (severity: 1, mild; 2, moderate; 3, severe; and 4, life-threatening). Cardiac function was determined before treatment and was monitored by electrocardiography, by Multiple Gated Acquisition scan, or by echocardiography on day 22 after initiation of therapy to assess potential cardiotoxicity.

Detection of scFv(FRP5)-ETA plasma levels by sandwich ELISA
Ninety-six-well microtiter plates (Greiner Bio-One, Frickenhausen, Germany) were coated overnight with 100 µl/well of 9 µg/ml goat anti-exotoxin A capture antibody (List Biological Laboratories, Campbell, CA, USA) diluted in 50 mM carbonate buffer, pH 9.5. After washing with PBS, the plates were blocked for 2 hours with PBS containing 1% BSA. For standard, control or patients' samples, 100 µl/well serum diluted 1:10 with PBS containing 6 mM ethylenediamine tetraacetic acid were added in duplicate, and were incubated for 2.5 hours at 37°C. After washing with PBS, 100 µl rabbit anti-exotoxin A antibody [9], diluted 1:250 in PBS, were added to each well for 1 hour at 37°C. After another washing step, bound rabbit antibodies were detected with 100 µl/well horse-radish peroxidase-coupled anti-rabbit IgG antibody (American Biosciences, Freiburg, Germany) for 1 hour at 37°C, after a final wash followed by 100 µl/well tetramethyl-benzidine (Sigma-Aldrich, Deisenhofen, Germany) substrate solution for 5–15 min at room temperature. Then the reaction was stopped by adding 50 µl/well of 1 M HCl, and the absorbance at 450 nm was measured using a Wallac Victor 2 ELISA reader (PerkinElmer Wallac, Freiburg, Germany).

Pharmacokinetic analysis
The main parameters measured were C_{max} and the area under the concentration–time curve (AUC_{0–5 hrs}) of scFv(FRP5)-ETA at day 5, obtained from the individual concentration–time profiles (area under the concentration–time curve by trapezoidal rule) and using the software program TOPFIT® 2.0 (Fischer Verlag, Stuttgart, Germany). Furthermore, the elimination half-life and plasma clearance were determined from the concentration–time profiles using a noncompartmental approach from the TOPFIT Library.

Detection of circulating antibodies
Ninety-six-well microtiter plates (Greiner Bio-One) were coated overnight with 100 µl/well of 1 µg/ml scFv(FRP5)-ETA in PBS. After washing with PBS, the plates were blocked for 2 hours with PBS containing 1% BSA. For standard, control or patients' samples, 100 µl/well serum diluted 1:50 with PBS were added in duplicate, and were incubated for 3 hours at 37°C. After washing with Tris-buffered saline, 100 µl alkaline phosphatase-coupled rabbit anti-human IgG/IgM antibody (Sigma-Aldrich), diluted 1:2000 in PBS, were added to each well for 1 hour at 37°C, after a final wash followed by 100 µl/well nitrophenylpyrophosphate substrate solution at room temperature. The absorbance at 450 nm was measured using a Wallac Victor 2 ELISA reader (PerkinElmer Wallac). Neutralizing antibodies were determined in cell viability assays as described previously [23].

Results
The primary objectives of the study were the determination of the maximum tolerated dose and the dose-limiting toxicity (grade 4 hematologic toxicity or grade 3 nonhematologic toxicity) of scFv(FRP5)-ETA after intravenous application. The secondary objectives were the determination of the pharmacokinetic profile of scFv(FRP5)-ETA, the time to progression, the objective response rate (complete and partial), and the immunological response to treatment.

Eighteen patients suffering from ErbB2-expressing metastatic breast cancers (13 patients), prostate cancers (two patients), head and neck cancer (one patient), non small cell lung cancer (one patient), or transitional cell carcinoma (one patient) (Table 1) were given at least five daily infusions of scFv(FRP5)-ETA at day 5, obtained from the individual concentration–time profiles (area under the concentration–time curve by trapezoidal rule) and using the software program TOPFIT® 2.0 (Fischer Verlag, Stuttgart, Germany). Furthermore, the elimination half-life and plasma clearance were determined from the concentration–time profiles using a noncompartmental approach from the TOPFIT Library.
12.5 µg/kg scFv(FRP5)-ETA received the complete dose without experiencing severe side effects. In one patient at this dose level, however, therapy had to be stopped on day 8 due to toxicity. No objective response was observed in any of the patients, but two patients remained in stable disease for more than 3 months, and clinical signs of activity were seen in three patients.

**Toxicity**

An increase in the serum levels of liver enzymes was found in the majority of the patients, with grade 1–2 elevation of ALT or AST seen in seven patients and grade 1–2 elevation of gamma-glutamyl transferase in six patients. A dose-limiting toxicity with grade 3–4 elevation of ALT or AST was found in two of three patients treated at 20 µg/kg scFv(FRP5)-ETA and in one patient treated at 12.5 µg/kg scFv(FRP5)-ETA, resulting in discontinuation of therapy in these patients on day 8. Enzyme levels returned to baseline values within 14 days after cessation of therapy in all patients. One patient with liver metastases, treated at the lowest dose level (2 µg/kg), developed cholestasis, which was due to massive disease progression but was unrelated to treatment, requiring a cessation of therapy on day 10. Another patient developed fever and dyspnoea on day 23 after onset of therapy, which resolved with antibiotics. However, this patient died on day 40, most probably unrelated to therapy but due to massive disease progression.

**Table 2**

| Patient | Dose level (µg/kg) | Course of therapy | Toxicities ≥ grade 1 | Dose-limiting toxicity | Neutralizing antibodies | Clinical response |
|---------|-------------------|-------------------|---------------------|-----------------------|-------------------------|------------------|

ALT, alanine aminotransferase; AST, aspartate aminotransferase; GGT, gamma-glutamyl transferase; n.d., not determined.  
aCausal relationship with study drug unlikely.  
bPatient U03 developed fever and dyspnoea after therapy on day 23, which was resolved with antibiotics; the patient died on day 40, causal relationship with study drug unlikely.  
cClinical signs of activity while on therapy including healing of cutaneous lesion (U03, U04), size reduction of lymph node metastasis (U03), and inflammatory response and softening of large tumor mass (N12).
the severity of the patients’ disease and their tumor load. Stable disease was seen in two patients, however: one prostate cancer patient treated at 10 µg/kg scFv(FRP5)-ETA per day, and one breast cancer patient treated at 12.5 µg/kg scFv(FRP5)-ETA per day. Furthermore, clinical signs of activity were observed in another three patients, with two patients treated at 10 and 12.5 µg/kg scFv(FRP5)-ETA per day experiencing signs of healing of cancer-related cutaneous lesions. In the patient receiving 10 µg/kg scFv(FRP5)-ETA, a reduction in the size of a cervical lymph node metastasis was also observed and the morphine dose could be reduced by 50%. A third patient treated at 20 µg/kg scFv(FRP5)-ETA per day, despite discontinuation of treatment on day 8 due to dose-related side effects, demonstrated signs of an inflammatory response and softening of a large tumor mass in her right breast. Interestingly, the breast cancer patient with stable disease and two of the patients with clinical signs of activity had previously progressed under therapy with trastuzumab (Table 1).

**Pharmacokinetic profile**

No scFv(FRP5)-ETA could be detected in patient plasma at the 2 µg/kg dose. At dose levels equal to or greater than 4 µg/kg scFv(FRP5)-ETA per day, there was a good correlation between the dose level and the plasma concentration, with peak levels of scFv(FRP5)-ETA reached 15 min after the beginning of infusion, and a fast decline to baseline levels within 4 hours, indicating that the drug was not accumulating (Fig. 1a). Peak concentrations at steady state (day 5 of therapy) ranged from 18 to 49 ng/ml (mean, 39 ng/ml) at 4 µg/kg scFv(FRP5)-ETA, ranged from 128 to 129 ng/ml (mean, 129 ng/ml) at 10 µg/kg scFv(FRP5)-ETA, ranged from 93 to 204 ng/ml (mean, 160 ng/ml) at 12.5 µg/kg scFv(FRP5)-ETA, and ranged from 115 to 307 ng/ml (mean, 236 ng/ml) at 20 µg/kg scFv(FRP5)-ETA (Fig. 2a). The correlation between the dose of scFv(FRP5)-ETA and the area under the concentration–time curve was less pronounced (Figs 1b and 2b). Plasma clearance was calculated as 6.6 l/hour at 4 µg/kg, as 5.3 l/hour at 10 µg/kg, as 4.9 l/hour at 12.5 µg/kg, and as 3.8 l/hour at 20 µg/kg. The calculated half-life of scFv(FRP5)-ETA at the three higher dose levels was approximately 44 min. The pharmacokinetic data are summarized in Table 3.

**Immunogenicity**

Antibody responses to scFv(FRP5)-ETA were analyzed in detail in 13 patients. None of the patients had pre-existing antibodies reactive with scFv(FRP5)-ETA, but most patients developed antibodies to scFv(FRP5)-ETA beginning on day 8 after onset of therapy, as determined by ELISA (Fig. 3). Only in five patients, however, could antibodies with neutralizing capacity against scFv(FRP5)-ETA be detected in cell viability assays. A strong neutralizing capacity (neutralizing activity at a serum dilution of 1:100) was only seen in two patients, whereas another three patients developed weak or moderate neutralizing activity (neutralizing activity only at a serum dilution of 1:50) (data not shown). Clinical symptoms were not associated with these responses (Table 2).

**Discussion**

Previous experimental work in various rodent models provided evidence for efficacy of the recombinant antibody toxin scFv(FRP5)-ETA against ErbB2-expressing tumors [9,10,14,16,18,19]. Further support for the use of
scFv(FRP5)-ETA in tumor therapy arose from a study investigating intratumoral injection of the antibody toxin in patients with dermal metastases of ErbB2-expressing tumors [23]. Here we report results on the first systemic application of scFv(FRP5)-ETA in cancer patients, demonstrating safety at doses up to 12.5 μg/kg per day.

The predominant dose-limiting toxicity encountered in two of three patients treated at 20 μg/kg was transient liver toxicity, as indicated by a grade 3-4 elevation of serum liver enzymes (patient N10, ALT grade 4, AST grade 3; patient N12, ALT grade 3). An amendment to the protocol was implemented to test a dose level of 12.5 μg/kg. Liver toxicity (elevation of ALT/AST grade 3) was observed at this amended dose level in only one out of six patients. Therefore, 12.5 μg/kg was determined as the maximum tolerated dose. Liver toxicity can be a common complication encountered after treatment with recombinant toxins based on ETA. This was drastically demonstrated in a clinical study using erb-38, an ErbB2-specific toxin similar to scFv(FRP5)-ETA, which consists of a disulfide-bridged Fv fragment of the ErbB2-specific monoclonal antibody e23 linked to truncated *Pseudomonas* toxin [21]. Intravenous injection of 1 or 2 μg/kg recombinant protein every other day caused liver toxicity in all patients after 3 days of treatment [22]. This approximately 10-fold difference in the daily doses causing liver toxicity when comparing erb-38 with scFv(FRP5)-ETA might be explained by direct adverse effects of erb-38 against hepatocytes due to low ErbB2 expression in the liver, as postulated by Pai-Scherf and colleagues [22].

In tissue culture, scFv(FRP5)-ETA displayed selective cytotoxicity towards ErbB2-overexpressing tumor cells with IC50 values in the nanograms per milliliter range [9,17]. While scFv(FRP5)-ETA and other ErbB2-specific antibody toxins have not been compared directly, the same cell lines and similar assays were used in some studies for in vitro characterization. For example, when tested in protein synthesis inhibition assays, scFv(FRP5)-ETA displayed an IC50 value towards SKBR3 breast carcinoma cells of 29 ng/ml [9], compared with a value of 32 ng/ml for e23(Fv)PE40, an ErbB2-specific molecule employing a scFv antibody fragment of e23 for cell targeting [20]. Improved cytotoxic activity was reported for erb-38 [21], which might indeed explain the higher degree of toxicity of this antibody toxin in cancer patients. It is noteworthy, however, that significantly lower toxicity of scFv(FRP5)-ETA was also seen in animal experiments, where specific binding to endogenous ErbB2 on liver cells can be excluded as the cause for toxicity. ScFv(FRP5)-ETA could be applied intravenously in mice at doses up to 1 mg/kg daily for 10 days without causing any measurable side effects [19]. This contrasts with erb-38, for which an LD50 value in mice of 450 μg/kg was reported after three doses given every other day, and which caused death of animals by hepatic failure [22].

Various studies link the hepatotoxic effects of *Pseudomonas* exotoxin to the increased production of tumor necrosis factor alpha (TNF-α) by Kupffer cells in the liver and the resulting liver damage from activated T cells [27]. Mice depleted of T cells prior to ETA challenge failed to develop acute hepatic failure, whereas mice not immunologically compromised demonstrated hepatocyte apoptosis and increased plasma transaminase activity. Furthermore, in mice treated with the ETA-containing antibody toxin LMB-2, inhibition of TNF-α production in Kupffer cells by a specific TNF-binding protein or indomethacin prevented LMB-2-induced liver damage [28]. Agents such as infliximab, which neutralize the effects of TNF-α, are currently in clinical use for the treatment of rheumatoid arthritis and Crohn’s disease [29]. These substances as well as nonsteroidal anti-inflammatory drugs may also be of use in preventing some of the unspecific toxic effects of ETA-based antibody toxins in humans.
Generally, cross-reactivity with normal tissues and severity of adverse reactions might at least in part depend also on the nature and the position of the epitope recognized by the antibody domain [30]. The mAb FRP5 and its scFv derivatives recognize a peptide epitope located in the N-terminal region of the receptor [14,31]. In contrast, the humanized ErbB2-specific antibody Herceptin™ (trastuzumab), which can induce cardiotoxicity in some patients [32], recognizes the juxtamembrane region of ErbB2 [33]. As in a previous study with locally applied scFv(FRP5)-ETA [23], here we have not observed cardiovascular complications in any of the patients treated with scFv(FRP5)-ETA, nor were such toxicities reported for the erb-38 molecule based on mAb e23 [22], for which information on the binding epitope is not available.

Our results demonstrate that intravenous administration of scFv(FRP5)-ETA leads to serum concentrations of the recombinant protein over several hours, predicted to be therapeutically relevant. IC50 values ranging from 10 to 100 ng/ml were determined on treatment day 5. Thereby a tendency towards a lower circulation half-life and lower area under the concentration–time curve values was found when compared with lower circulation half-life and lower area under the concentration–time curve values was found when compared with

AUC, area under the concentration–time curve; n.d., not determined.

Antibody responses to scFv(FRP5)-ETA were analyzed in 13 patients. While none of these patients had pre-existing antibodies to ETA, they all developed antibody responses of varying intensity to scFv(FRP5)-ETA measurable after 8 days of therapy. Importantly, only in five of the 13 patients analyzed did these antibodies have scFv(FRP5)-ETA neutralizing activity, and two of these patients had stable disease for longer than 3 months. The pharmacokinetic parameters shown were determined on treatment day 5. Thereby a tendency towards a lower circulation half-life and lower area under the concentration–time curve values was found when compared with treatment day 1 (data not shown). This could at least partially be due to onset of anti-toxin antibody responses. During the second week of treatment, anti-toxin antibodies might have affected the half-life of scFv(FRP5)-ETA further, which was not formally investigated. Nevertheless, in a previous study, complete remission of tumor nodules locally injected with scFv(FRP5)-ETA could be achieved after a second treatment cycle despite pre-existing neutralizing antibodies induced during the first round of treatment [28]. Continued treatment of patients after development of anti-toxin antibodies might therefore still be efficacious.

**Conclusion**

Taken together, our results demonstrate that the ErbB2-specific antibody toxin scFv(FRP5)-ETA can be safely adminis-
tered intravenously at doses up to 12.5 µg/kg per day to treat cancer patients with ErbB2-overexpressing tumors. Thereby, serum concentrations of the drug were reached that could be of therapeutic value. The major dose-limiting side effect of scFv(FRP5)-ETA was hepatotoxicity. This may become controllable in future studies by using TNF neutralizing reagents or by temporary suppression of T-cell activation. Whether the development of neutralizing antibodies will limit the therapeutic utility of the antibody toxin or whether alternative treatment schedules or immunosuppressant co-medication can overcome this problem remains unclear at present. To further investigate the efficacy of systemic scFv(FRP5)-ETA therapy in cancer patients, we recommend the dose of 12.5 µg/kg for subsequent, carefully planned phase II studies.

Competing interests
G2M Cancer Drugs AG holds rights for commercial development of the study drug scFv(FRP5)-ETA. ABM, SHö and AAb have contributed to the study as employees of G2M AG. WSW is a shareholder of G2M AG. GvM, SHA, EJ, SEAB, SL, AA1, CC, AN, AK, MK and DJ declare that they have no competing interests.

Authors’ contributions
GvM, ABM, DJ, AK, MK, EJ, SHa and WSW participated in the design and coordination of the study. GvM, DJ, EJ, SEAB, SL, AA1, CC, AK and MK provided the clinical data. ABM, SHö, SHA, AAb and AN performed and evaluated the assays to determine pharmacokinetic parameters and antibody responses to scFv(FRP5)-ETA. WSW, ABM, SHö, SHA and GvM drafted the manuscript. All authors read and approved the final manuscript.

Acknowledgements
The authors thank Dr Bernd Groner, Dr Marc Azemar, and Dr Bernd Hentsch for helpful discussions and organizational support, and thank Barbara Uherek for scFv(FRP5)-ETA activity measurements. This work was supported in part by a grant from the National Genome Research Network program of the German ‘Bundesministerium für Bildung und Forschung’.
