Abstract

AIM
To investigate suicidality and attention-deficit/hyperactivity disorder (ADHD), this paper aims to systematically review the literature as an extension of previous reviews.

METHODS
We searched five databases (Ovid MEDLINE, Psychinfo, PubMed, Scopus, Web of Science) with two categories of search terms: (1) suicide; suicidal; suicide behavior; suicide attempt; suicidal thought; and (2) ADHD.

RESULTS
The search resulted 26 articles. There is a positive association between ADHD and suicidality in both sexes and in all age groups. Comorbid disorders mediate between suicidality and ADHD.

CONCLUSION
Recognizing ADHD, comorbid conditions and suicidality is important in prevention.

Key words: Attention-deficit/hyperactivity disorder; Suicide; Systematic review

© The Author(s) 2017. Published by Baishideng Publishing Group Inc. All rights reserved.

Core tip: This review of the last four years strengthens previous findings that there is a positive association between attention-deficit/hyperactivity disorder (ADHD) and suicidality in both sexes and in all age groups. Suicidality should screen in patients with ADHD. Comorbidity disorders mediate between suicidality and ADHD. Recognizing ADHD and comorbid conditions can be important in suicide prevention as well.

Balazs J, Kereszteny A. Attention-deficit/hyperactivity disorder and suicide: A systematic review. World J Psychiatry 2017; 7(1):
INTRODUCTION

Suicide prevention is a public health issue all over the world[1]. Recently, several studies have focused on attention-deficit hyperactivity disorder (ADHD) as a possible psychiatric disorder that may serve as a suicide risk factor as well[2-5]. One of the theoretical backgrounds of it is the construct of impulsivity, which is a well-know personality trait. Impulsivity is a core symptom of ADHD[6,7], moreover it is known, that it correlates to suicidal behavior[8]. Another theoretical background behind the possible association between ADHD and suicide is, that two-thirds of ADHD cases have at least one comorbid psychiatric diagnosis, which most often is conduct disorder, substance use or major depressive episode[9-11]. These comorbid disorders are well-known risk factors of suicide[12-15]. As ADHD is one of the most prevalent (2%-12%) psychiatric disorders among children and adolescents and in 40%-60% of the cases, it continues into adulthood[16,17], all additional knowledge on the possible association between ADHD and suicidality has high clinical importance and can add to suicide prevention.

The growing body of publications on ADHD and suicidality has already resulted in five review or summary papers on this topic. First, James et al[18] searched two electronic databases (MEDLINE, Psychlit) for the period from 1966 to 2003. In their review, they included psychological autopsy studies of teenage and young adult suicides and long-term follow-up studies of ADHD children. They found a positive association between ADHD and completed suicides in males, concluding that ADHD could increase the risk for suicide through comorbid conditions such as conduct disorder and depression. Second, Impey et al[19] performed a search for the period up to January 2011 using three main databases (MEDLINE, EMBASE and PSYCHINFO). They concluded from their review that most suicidal study groups showed a higher rate of ADHD than the controls: At least double the rate for suicidal ideation and around 1.5-2.0 times for suicide attempts and completion. The authors emphasized that comorbidity had a large influence, especially in the cases of delinquency and substance misuse. Third, Furczyk et al[20] published a selective review on the most important currently known associations between ADHD and suicidality. They concluded, similar to the previous reviews[16,19], that there is substantial evidence supporting an association between ADHD and increased suicide risk, and that it is at least partially mediated by comorbidities. They highlight the importance of raising the awareness of health professionals of the risk of suicide in ADHD patients, but further research on the long-term outcomes of the treatment of ADHD patients with a risk of suicide is needed. The selective review paper of Nigg[21] had a wider focus: He overviewed the current knowledge on the health-related impairments of ADHD, including smoking, drug abuse, accidental injury, sleep, obesity, hypertension and diabetes, as well as suicidal behavior. On the topic of ADHD and suicide, the author concluded that ADHD is associated with an elevated risk of suicide attempts (particularly in girls) and completed suicide (particularly in boys), and this risk is mediated by comorbid disorders, which may vary with gender: They include conduct and emotional problems in males and depression in females. Finally, we have to mention Renaud et al[22] summary paper: Based on some selected important research in the field, the authors concluded that there is not a direct link between ADHD and suicide, however; ADHD’s constructs of impulsivity and aggression are related to the development of conduct and oppositional defiant disorders, which can lead to deviancy and drug abuse; all of these comorbid conditions increase the risk of suicide.

Knowing of the growing interest in this topic over the last couple of years, we found it useful to conduct an up-to-date systematic review, which can provide important extensions. The search of James et al[18] was conducted more than one decade ago, and even Impey et al[19] completed their search in January, 2011. The most recently published reviews were not systematic[20-22]. Additionally, all of the reviews have mainly been limited to males[18,19]. Moreover knowing more about the methodology of the studies can lead to a better understanding of the prevalence data. Considering all of this, the current systematic review aims to present an overview on suicidality and ADHD as an extension of the previous ones, not only in the time period of the search, but also by focusing on the following topics: (1) Is ADHD more common in people who are suicidal? (2) Is suicide more prevalent in people with ADHD? and (3) Which other identifiable risk factors can be associated with suicide in ADHD?

Additionally, to be able to compare the included studies, we investigated what kinds of assessments are used for measuring ADHD, suicidality and comorbid conditions.

MATERIALS AND METHODS

Selection of publications

A systematic literature search was conducted in the following five computerized literature databases on January 27, 2015: Ovid MEDLINE, Psychinfo, PubMed, Scopus, Web of Science from 2011 to 2015. Search terms from two categories were used: (1) suicide; suicidal; suicide behavior; suicide attempt; suicidal thought; and (2) ADHD; attention deficit hyperactivity disorder. Search terms within both categories were separated by the Boolean operator OR, and the categories were separated by the operator AND. Using prespecified inclusion and exclusion criteria, we screened
the titles and/or abstracts. The relevant full texts of papers that passed the first search were read, and the ones that met the inclusion criteria were collected. The reference lists of the retrieved papers were screened, and papers that possibly met the inclusion criteria were retrieved and studied. The inclusion criteria were: Peer-reviewed journals; publications written in English or Hungarian. The exclusion criterion was the lack of any empirical data. It was not in the focus of our study to examine suicidal behavior, as a safety concern about ADHD drug treatment. We excluded those studies, which aim was to examine pharmacological treatment (e.g., atomoxetine) induced suicide in patients with ADHD, e.g., Capuano et al.\(^{23}\), who present a series of cases of Italian children who experienced suicidal ideation during ADHD pharmacological therapy with atomoxetine.

**RESULTS**

**Included studies**
The search strategy resulted in a total of 278 articles (excluding duplicates), of which 26 were included in the systematic review after the screening process (Figure 1, Tables 1-3).

The 26 papers were written in 16 countries on four continents. Of the 26 studies, only two had a longitudinal design. Detailed information on the origin, design, sample and instruments of the studies can be found in Tables 1-3.

**Is ADHD more common in people who are suicidal?**
Table 1 summarizes the three studies on ADHD in suicidal patients\(^{24-26}\).

**Is suicide more prevalent in people with ADHD?**
Table 2 includes the 14 studies, which examines suicidality in patients with ADHD\(^{27-40}\).

**Which other identifiable risk factors can be associated with suicide in ADHD?**

**Gender differences in suicidality and ADHD:** Examining the gender distribution of ADHD cases among suicidal patients, only one study provided relevant data\(^{24}\): 8.6% of suicidal male adolescents had ADHD, and 4.7% of suicidal female adolescents had ADHD.

Focusing on the gender differences in suicidal cases among ADHD patients, in the above-described 12...
papers, which examined the prevalence of suicidality among patients with ADHD, three studies focused on gender differences[27,36,37], and one study enrolled only girls[38].

Regarding suicidal ideation, Mayes et al[37] found no differences between boys and girls with ADHD with suicidal ideation (18% and 11%, respectively). All three studies examined the gender of those who attempted suicide among ADHD patients, and two did not find differences[38,37]. Agosti et al[27] found that 52.9% of patients with ADHD who had previous suicide attempts were male, while the rate of males was 58.3% in patients with ADHD without previous suicide attempts. Mayes et al[37] found no differences between boys and girls with ADHD and suicidal ideation (7% and 3%, respectively). Ljung et al[35] found that the risk of suicide attempts among ADHD patients differed significantly by gender ($\chi^2 = 1271.0; P < 0.001$): The adjusted estimate was 2.93 (95%CI: 2.60-3.29) for males and 5.41 (95%CI: 4.60-6.36) for females. Only one study examined gender differences in ADHD patients who completed suicide[35] and found no gender differences.

**Suicidality in patients with psychiatric disorders who have ADHD comorbidity:** Table 3 summarizes the seven studies among the 26, which investigated ADHD, as a comorbid condition of other psychiatric disorders, and its association with suicidality[30,41-46].

**Suicidality in ADHD patients who have psychiatric comorbidity:** From the 26 papers of this review, the 10 studies, which investigated comorbidity in ADHD patients with suicidality are presented in Table 4[27,28,36-39,47,48].

**Assessments for measuring ADHD, suicidality and comorbid conditions**

**Assessments for measuring ADHD:** Table 5[49-55] summarizes assessments for measuring ADHD.

Table 2 Included relevant articles examining attention-deficit/hyperactivity disorder and suicidality from January 2011 to January 2015: Suicidality in patients with attention-deficit/hyperactivity disorder

| Ref. | Country | Study design | Sample | Population at onset | Population's age at onset | Measures for ADHD, comorbid conditions and suicidality | Main findings |
|------|---------|--------------|--------|---------------------|---------------------------|------------------------------------------------------|---------------|
| Agosti et al** | United States | Cross-sectional | Clinical sample | Current ADHD: 365 adults: With Suicide attempts: \( n = 59 \)
No suicide attempts: \( n = 306 \) | Age range: 18-66 yr | CIDL, ACDS, DIS-IV | Sixteen percentage of participants with current ADHD diagnosis had previous suicide attempt. While ADHD increased the risk of previous suicide attempt only 1.5 fold, having one or more comorbid disorders increased the risk of previous suicide attempt 4 to 12 fold. |
| Balazs et al** | Hungary | Cross-sectional | Clinical sample | ADHD and subthreshold ADHD children: \( n = 220 \) ADHD and subthreshold ADHD adolescents: \( n = 198 \) Children: Age range: 3-11 yr Mean age: 7.67 yr (SD = 2.03) Adolescents: Age range: 12-17 yr Mean age: 14.31 yr (SD = 1.67) | MINI-KID | The relationship between ADHD and suicidality was fully mediated by comorbid psychiatric disorders. In children, symptoms of anxiety disorders mediated this relationship, while in the adolescent group, symptoms of major depressive episode, dysthymia, and substance abuse/dependence were found to be significant mediators. |
| Barbaresi et al** | United States | Cross-sectional | Community sample | Adults with childhood ADHD: \( n = 232 \) Non-ADHD controls: \( n = 335 \) | ADHD group: Mean age: 27 yr Non-ADHD group: Mean age: 28.6 yr | MINI | The rate of death from suicide was significantly higher among adults with childhood ADHD compared to non-ADHD adults. |
| Cheng et al** | Taiwan | Cross-sectional | Community sample | 5405 University students: \( n = 5405 \) (male ratio: 64.8%) ADHD symptoms were elevated in 8.6% of the sample: (male ratio: 75.1%) | University students | ASRS, BSRS-5 | Individuals with higher levels of ADHD symptoms were more likely to have higher suicidal ideation. |
| Huntley et al** | United Kingdom | Cross-sectional | Clinical Sample | Participants from two in-patient alcohol and drug detoxification units: \( n = 226 \) (male ratio: 76.5%) Patient with alcohol/drug intoxication + ADHD: \( n = 11 \) Patient with alcohol/drug intoxication without ADHD: \( n = 183 \) ADHD adolescents: \( n = 104 \) Non-ADHD adolescents: \( n = 169 \) | Mean age: 39.0 yr (SD = 10.3) | DSM-IV 18-item self-report ADHD screening questionnaires for both current and childhood behavior impairment questions from the Barkley scales DIVA | Patients with both substance use disorders and ADHD had significantly higher rates of prior suicide attempts than patients with substance use disorder without ADHD. |
| Hurtig et al** | Finland | Longitudinal: 16 yr. First follow up: at ages 7, 8, second follow up at ages 15, 16 | Community sample | Adolescents from the same birth cohort At 8 yr of age: Rutter B2 During the 15-16 yr follow up: SWAN, K-SADS-PL | | | Adolescents with ADHD had more suicide ideation, acts than adolescents without ADHD. The effect of ADHD on suicidal ideation remained strong after controlling for other variables. |
| Kavakci et al** | Turkey | Cross-sectional | Community sample | 980 university students (male ratio: 55.9%) ADHD: \( n = 48 \) Non-ADHD: \( n = 932 \) | Age range: 17-44 yr Mean age: 21.4 yr (SD = 2.3 yr) | ASRS, SCID I, SCID II, Adult ADHD Module of MINI Plus | Adolescents with ADHD reported significantly more lifetime suicide attempts than those without ADHD. |
Keresztény et al. [34] Hungary  Cross-sectional  Clinical sample  Children:  $n = 168$  (male ratio: 87.5%)  Adolescents:  $n = 43$  (male ratio: 62.8%)  **Children:**  Age range: 3-12 yr  Mean age: 8.23 yr  (SD = 2.22)  **Adolescents:**  Mean age: 14.65 yr  (SD = 1.6 yr)  boys: 27  (62.8%)  MINI-KID  The most common comorbid diagnoses with ADHD were oppositional defiant disorder, conduct disorder and suicide behavior in both age-groups. The rate of suicide behavior was 17% among children and 58% among adolescents  

Ljung et al. [35] Sweden  Cross-sectional  Patient and prescribed drug registers and population-based registers  ADHD:  $n = 51707$  (male ratio: 69.8%)  Control:  $n = 258535$  Age range: 3-40 yr  Discharge diagnosis of ADHD  Participants with ADHD had an increased risks of both attempted and completed suicide compared with control participants. This result was the same even after adjusting for comorbid psychiatric conditions. While the highest familial risk was reported among first-degree relatives, lower risk was observed among more genetically distant relatives. The results suggests that shared genetic factors are important for this association  

Mayes et al. [36] United States  Cross-sectional  Community and clinical sample  1706 children and adolescents with psychiatric disorders and typical development:  ADHD-C:  $n = 566$  (male ratio: 74.6%)  ADHD-I:  $n = 235$  (male ratio: 57.4%)  Other psychiatric disorders (autism, depression/ anxiety, eating disorder, intellectual disability):  $n = 719$  (male ratio: 62.2%)  Typical:  $n = 186$  (male ratio: 43.3%)  All participants had a clinical diagnosis of ADHD made by a licensed PhD psychologist. The clinical diagnosis was based on a comprehensive psychological evaluation including diagnostic interviews with the parent and child, parent and teacher rating scales, review of educational and medical records, extensive psychological testing  PBS  All psychiatric groups had far more suicide behavior than typically developed children. ADHD-C: 20.7% had suicide ideation, 6.0% attempt  ADHD-I: 7.3% had suicide ideation, 2.6% attempt  

Mayes et al. [37] United States  Cross-sectional  Clinical sample  Children and adolescents with ADHD:  $n = 925$  (male ratio: 68.5%)  ADHD-C:  $n = 666$  ADHD-I:  $n = 259$  Age range: 3-16 yr  Mean age: 8.8 yr  (SD = 2.6)  All participants had a clinical diagnosis of ADHD made by a licensed PhD psychologist. The clinical diagnosis was based on a comprehensive psychological evaluation including diagnostic interviews with the parent and child, parent and teacher rating scales, review of educational and medical records, extensive psychological testing  PBS  For the total sample with ADHD, 15.8% had suicide ideation (sometimes or more) and 5.5% had attempts Ideation and attempts were more than twice as prevalent among participants with ADHD-C than among participants with ADHD-I  ADHD-C: 19% had suicide ideation, 7% attempt  ADHD-I: 7% had suicide ideation, 3% attempt  Those, who had ADHD alone: 6% had suicide ideation and 2% had suicide attempt  Those, who had ADHD + co-occurring sadness and ODD, 46% had ideation and 21% had attempts  

Park et al. [38] South Korea  Cross-sectional  Community sample  A total of 6081 subjects:  Non-ADHD symptom group:  $n = 6012$  ADHD symptom group:  $n = 69$  Age range: 18-59 yr  K-CIDI  Adult ADHD Self-Report Scale  Adult ADHD symptoms are significantly associated with lifetime suicidality. However, the association disappeared after adjusting for other comorbid psychiatric disorders
ADHD: Attention-deficit/hyperactivity disorder; CIDI: Composite International Diagnostic Interview; ACDS: Adult ADHD Clinical Diagnostic Scale; DIS-IV: The Diagnostic Interview Schedule for DSM-IV; MINI-KID: Mini-International Neuropsychiatric Interview for children and adolescents; PBS: Pediatric Behavior Scale; MINI: Mini-International Neuropsychiatric Interview; ASRS: Adult Self-Report Scale; BSRBS-S: Brief Symptoms Rating Scale; DIVA: Diagnostic Interview for ADHD in Adults; SWAN: Strengths and Weaknesses of ADHD symptoms and Normal Behaviors; SCID-I: Structured Clinical Interview for DSM-IV Axis I Disorders; ODD: Oppositional defiant disorder; K-CIDI: Korean version of Composite International Diagnostic Interview; SNAP-IV: Swanson, Nolan, and Pelham Rating Scale; SIQ: Self-Injury Questionnaire; DISC-IV-YA: Diagnostic Interview Schedule for Children 4th ed., Young Adult version; ADHD-C: ADHD combined type; ADHD-I: ADHD inattentive type, ADHD-HKS Questionnaire.

| Study | Country | Design | Sample | ADHD | Age at Ascert. | At Ascert. | Gender | Comorbid Conditions | DISCUSSION |
|-------|---------|--------|--------|------|---------------|------------|--------|-------------------|------------|
| Swanson et al. | United States | Longitudinal | 10 yr: 1st 5 yr follow-up and 2nd 10 yr follow-up | ADHD girls: n = 140 | Age range: 6-12 yr | Mean age at 5 yr follow-up: 14.2 yr | | | This review of the last four years strengthens the recent finding that ADHD is related to high suicidality in all age groups and in both girls and boys. Although our current systematic review was conducted only for the last four years, we still found 26 papers that presented data on ADHD and suicidality. Moreover, we know that several systematic review papers and overviews had been done previously. Impey et al., who performed a systematic search on the same topic, covering all studies up to January 2011, the starting point of our search period, found 25 papers. All of them support the view that research on the association of ADHD and suicidality is a subject of high and growing interest, and clinicians and researchers need to have access to up-to-date knowledge in this field. The studies of this review are culturally diverse, as they come from four continents. This shows that this topic has relevance all over the world and that the conclusions can be used in wider aspects. Regarding the age groups investigated on the topic of ADHD and suicidality, the studies have been balanced over the last four years: Exactly half of them investigated children/adolescents, and half of them examined adults. This reflects the growing interest in ADHD in adulthood among both healthcare professionals and researchers. Considering the previous studies on this topic - which were included in the review of Impey et al. - a majority of them involved the 12-18 age group, although there were a few studies in older and younger age groups as well. Additionally, in their review, Impey et al. concluded that, based on the studies included in their review paper, age differences were not clearly definable. In this way, the current review extends our knowledge with further information on all age groups with ADHD and suicidality, including children under 12 and adults, and makes it possible to compare different age groups. Systematically searching the literature of the last four years, we found only two studies that reported the prevalence data of ADHD among patients with suicidality, however, there were a total of six studies addressing that study question in the review of Impey et al. There were five in the review of James et al., but four of them were included in the review of Impey et al. as well. In both studies in the current review, the diagnoses of ADHD and suicidality were based on a clinician’s opinion. A very important and new result shown in our review is that one-quarter of the suicidal children under 12 years old had ADHD. The prevalence rate of ADHD among suicidal adolescents was lower (5.7%) than in children, and it was lower than in previous studies. One possible explanation could be that these studies did not use either diagnostic interviews or screening tools for the diagnoses of ADHD and suicidality. All of them show that there is still limited data on the prevalence of ADHD among patients with suicidality; however, all of the studies performed found a high prevalence of ADHD in this population, especially among young children. Further studies are needed, but based on the current knowledge, we suggest a routine screening for ADHD patients with suicidal thoughts and attempts, with a special focus on young children. |
### Table 3: Included relevant articles examining attention-deficit/hyperactivity disorder and suicidality from January 2011 to January 2015: Suicidality in patients with psychiatric disorders who have attention-deficit/hyperactivity disorder comorbidity

| Reference | Country | Study Design | Sample | Population at Onset | Population’s Age at Onset | Measures for ADHD, comorbid conditions and suicidality | Main Findings |
|-----------|---------|--------------|--------|---------------------|--------------------------|------------------------------------------------------|---------------|
| Bácskai et al.[41] | Hungary | Cross-sectional | Clinical sample | 198 patients with drug dependence (male ratio: 76%) | Age range: 18-40 yr Mean age of the whole sample: 27 yr (SD = 6.31) | ASRS, EuroADAD, BDI | Drug dependent patients with ADHD showed a significantly higher proportion of suicidal ideation, suicidal attempts and self-injuries associated with suicidal attempts than drug dependent patients without ADHD |
| Berkol et al.[42] | Turkey | Cross-sectional | Clinical sample | Patients with BD type I and II Adult BP with ADHD: n = 23 Adult BP without ADHD: n = 32 | BP adults with ADHD: Mean age: 35.1 yr (SD = 10.7) BP adults without ADHD: Mean age: 41.3 yr (SD = 13.0) | ADHD scale Mood disorder modular of SCID-I-CV | In the BP with ADHD group, the rate of suicide attempts (47.8%) was significantly higher than in the BP without ADHD group (21.9%) |
| Donev et al.[43] | Germany | Cross-sectional | Clinical sample | Patients with schizophrenia according to ICD-10 criteria: n = 27 (14 male) Patients with schizophrenia and no ADHD: n = 15 Patients with schizophrenia and ADHD: n = 12 | Age range: 18-44 yr Mean age: 25.7 yr (SD = 7.6) | ADHD-HKS Questionnaire | Among patients with both schizophrenia and ADHD there were significantly higher number of suicide attempts than among those with schizophrenia without ADHD |
| Huntley et al.[31] | United Kingdom | Cross-sectional | Clinical sample | Participants from two in-patient alcohol and drug detoxification units: n = 226 (male ratio: 76.5%) Patient with alcohol/drug intoxication + ADHD: n = 11 Patient with alcohol/drug intoxication without ADHD: n = 183 | Mean age: 39.0 yr (SD = 10.3) | DSM-IV 18-item self-report ADHD screening questionnaires for both current and childhood behavior impairment questions from the Barkley scales DIVA CSS, HDSQ | Patients with both substance use disorders and ADHD had significantly higher rates of prior suicide attempts than patients with substance use disorder without ADHD |
| Patros et al.[44] | United States | Cross-sectional | Community sample | College students: n = 1056 (male ratio: 38.5%) | Age range: 18 yr of age or older; 96.4% aged 18-24 yr | Higher hyperactive/attention symptoms were associated with increase in suicidal thoughts, suicide attempts, and need for medical attention after suicide attempts, among participants with depressed mood | Compared to all other clients, clients who attempted suicide in the past year were significantly more likely to have ADHD (9.2% vs 2.5%) |
| Penney et al.[45] | Canada | Cross-sectional | Clinical sample | Clients who presented for treatment at an addictions facility: n = 5990 (male ratio: 63.1%) Clients who reported being hospitalized for attempting suicide in the past year: n = 76 All other clients: n = 5914 | Age range: 11-86 yr Mean age: 32.60 yr (SD = 14.55) | Clients reported whether or not they had been diagnosed by a mental health professional in the last 12 mo and in their lifetime | |
Almost half of the papers reported prevalence data on suicidality in ADHD patients. The results strengthen the findings of previous studies\(^{[18-21]}\) that there is a positive association between ADHD and suicidality, including completed suicides, attempts, as well as ideation. We would like to highlight that, in adolescence, based on the studies of the last four years, more than half of the patients with ADHD had suicidal thoughts, and this prevalence rate is even higher than what has been described previously\(^{[19]}\). It is important to note that even in adulthood, one third of ADHD patients had suicidal ideation. Based on these results, we suggest the introduction of routine screening questions on suicidal thoughts in outpatient/inpatient ADHD clinics, both for those specializing in adults and those specializing in children/adolescents. This improvement in clinical practice can be an important step towards suicide prevention.

The rate of previous suicide attempts was the highest (16%) in the adult ADHD age group; however, adolescents need attention in this respect as well, as almost one-tenth of ADHD patients in this age group had a previous suicide attempt. As one of the strongest predictors of a completed suicide is a previous suicide attempt, close follow-up of these ADHD patients could be of core importance in suicide prevention.

When we examined, which identifiable risk factors can be associated with suicide in ADHD, first we focused on gender. There are still a limited number of studies examining gender differences within this topic. The only study\(^{[24]}\) that reported data on the gender distribution of suicidal patients with ADHD is in agreement with the conclusion of previous reviews\(^{[18,19]}\) that ADHD is present more often among suicidal men than suicidal women. However, when we examined the prevalence of suicidality (e.g., ideation, attempts and completed suicides) in ADHD patients, two out of three of the studies did not find a difference between men and women\(^{[27,37]}\), and one study reported an adjusted estimate for the risk of suicide attempts in females that was almost twice as high\(^{[38]}\). In his selected review paper, Nigg\(^{[31]}\) reported that girls had an elevated risk of a suicide attempt as well; however, the author stated that boys have a higher risk of completed suicide among ADHD patients. It is important to note that there are very few studies that have focused on female patients with ADHD\(^{[20]}\). One of them was conducted during the search period of this review\(^{[39]}\), while in the previous review on this topic, there were several studies in which only men were enrolled, as well as those in which both females and men were included\(^{[29]}\). Based on the currently available results, both females and males with ADHD need a special focus to recognize their possible suicide risk; however, further studies are needed to gain a better understanding of the gender differences in all age groups.

Second, when we examined identifiable risk factors, which can be associated with suicide in ADHD, we focused on comorbidities. One of the most exciting questions, which also has been raised in all of the previous review and summary papers\(^{[18-21]}\), is whether there is a direct association between ADHD and suicidality or if ADHD increases the risk of suicide through comorbid conditions. In the current review, we examined two aspects of this question. First, we reviewed all of the papers within the examined period that measured the prevalence of ADHD in suicidal patients with other psychiatric disorders, such as mood disorders, schizophrenia, alcohol/drug intoxication and chronic fatigue syndrome. The results of all seven studies on this topic showed that the prevalence of suicidality is higher when psychiatric disorders are comorbid with ADHD than in their absence. These findings suggest that the presence of ADHD, as a comorbid condition, conveys an increased risk of suicide for patients with other psychiatric disorders. Second, we

### Table 4  Included relevant articles examining attention-deficit/hyperactivity disorder and suicidality from January 2011 to January 2015: Suicidality in attention-deficit/hyperactivity disorder patients who have psychiatric comorbidity

| Ref. | Country     | Study design                  | Sample                                      | Population at onset | Population’s age at onset | Measures for ADHD, comorbid conditions and suicidality | Main findings                                                                 |
|------|-------------|--------------------------------|----------------------------------------------|---------------------|---------------------------|--------------------------------------------------------|-------------------------------------------------------------------------------|
| Agosti et al[27] | United States | Cross-sectional | Clinical sample | Current ADHD: 365 adults: With Suicide attempts: \( n = 59 \) No suicide attempts: \( n = 306 \) | Age range: 18-66 yr | CIDI, ACDS, DIS-IV | Sixteen percentage of participants with current ADHD diagnosis had previous suicide attempt. While ADHD increased the risk of previous suicide attempt only 1.5 fold, having one or more comorbid disorders increased the risk of previous suicide attempt 4 to 12 fold. |
| Balazs et al[28] | Hungary     | Cross-sectional | Clinical sample | ADHD and subthreshold ADHD children: \( n = 220 \) ADHD and subthreshold ADHD adolescents: \( n = 196 \) | Children: Age range: 3-11 yr Mean age: 7.67 yr (SD = 2.03) Adolescents: Age range: 12-17 yr Mean age: 14.31 yr (SD = 1.67) | MINI-KID | The relationship between ADHD and suicidality was fully mediated by comorbid psychiatric disorders. In children, symptoms of anxiety disorders mediated this relationship, while in the adolescent group, symptoms of major depressive episode, dysthymia, and substance abuse/dependence were found to be significant mediators. |
| Daviss et al[29] | Lebanon     | Cross-sectional | Clinical sample | Youth with ADHD: \( n = 101 \) (male ratio: 63.4%) Lifetime SBs: \( n = 28 \) (male ratio: 42.9%) No lifetime SBs: \( n = 73 \) (male ratio: 71.2%) | Age range in the whole sample: 11-18 yr Lifetime SBs: Mean age: 14.6 yr (SD = 2.1) No lifetime SBs: Mean age: 13.5 yr (SD = 1.8) | K-SADS-PL ADHD Rating Scale | In this ADHD sample, after controlling for the age, female sex, and comorbid disorders, lifetime SB remained significantly associated with parent-child conflict, and impairment in nonacademic domains of function and breadth of exposure to victimization events. Past and current ADHD symptoms and signs were not associated with lifetime SB. |
| Ljung et al[30] | Sweden      | Cross-sectional | Patient and prescribed drug registers and population-based registers | ADHD: \( n = 51707 \) (male ratio: 69.8%) Control: \( n = 258535 \) | Age range: 3-40 yr | Discharge diagnosis of ADHD | Participants with ADHD had an increased risk of both attempted and completed suicide compared with control participants. This result was the same even after adjusting for comorbid psychiatric conditions. While the highest familial risk was reported among first-degree relatives, lower risk was observed among more genetically distant relatives. The results suggests that shared genetic factors are important for this association. |

| All psychiatric groups had far more suicide behavior than typically developed children. ADHD-C: 20.7% had suicide ideation, 6.0% attempt  
  ADHD-I: 7.3% had suicide ideation, 2.6% attempt |  |  | |
investigated the role of comorbidity in ADHD patients with suicidality. The majority of the studies (7/9) found that comorbid disorders mediate between suicidality and ADHD\(^{[27,36,38-41,49]}\), which is in line with the conclusion of previous review papers\(^{[18-21]}\). It highlights the importance of raising clinicians’ awareness of the need to screen and treat comorbidity in ADHD, which may reduce suicidality as well.

These findings are limited in that only studies published in English and in Hungarian were included. Three potentially relevant studies were excluded because they were neither in English nor in Hungarian. The vast majority of the studies included in this review have a cross-sectional design, which limits the possible conclusions. Additionally, most of the studies that were conducted before this review paper have a cross-sectional design as well\(^{[19]}\). This should draw the attention of the researchers that, in the future, more studies are needed with a longitudinal design.

Additionally, similar to the previous review of Impey et al\(^{[19]}\), the measurement methods for both ADHD and suicidality in the studies included in the current review are very different, i.e., diagnostic interviews, rating questionnaires and clinician-made diagnoses - which means that a comparison of the

numerical results is not possible.

In conclusion, our systematic highlights that the early recognition and treatment of ADHD - either as a comorbid condition or as a main diagnosis- and the co-occurring psychiatric disorders, can play an important role in the secondary prevention of suicide. Additionally, it could be useful to incorporate routine measurements of suicidality in the daily practice of ADHD clinics.

COMMENTS

Background

Recently, several studies have focused on attention-deficit/hyperactivity disorder (ADHD) as a possible psychiatric disorder that may serve as a suicide risk factor as well. This paper presents a systematic review of suicidality and ADHD as an extension of previous reviews for the search period and with study questions.

Research frontiers

Suicide prevention is a public health issue all over the world. As ADHD is one of the most prevalent psychiatric disorders among children and adolescents and in 40%-60% of the cases, it continues into adulthood. All additional knowledge on the possible association between ADHD and suicidality has high clinical importance and can add to suicide prevention.

Innovations and breakthroughs

Although this systematic review was conducted only for the last four years, the authors still found 26 papers that presented data on ADHD and suicidality.

Applications

This systematic review strengthens the finding that ADHD is related to high suicidality in all age groups and in both girls and boys. It highlights that the early recognition and treatment of ADHD - either as a comorbid condition or as a main diagnosis - and the co-occurring psychiatric disorders, can play an important role in the secondary prevention of suicide.

Terminology

Attention-deficit/hyperactivity disorder: ADHD is a neurodevelopmental disorder with ongoing pattern of inattention and/or hyperactivity-impulsivity that interferes with functioning or development; Suicidality: It includes suicidal thought, suicidal plan, suicidal attempt and completed suicide; Systematic review: A systematic review is a type of literature review which aims to provide a thorough, complete, exhaustive summary of current literature relevant to a research question.

Peer review

The authors have reviewed the evidence for an association between ADHD and suicide. This is a descriptive review that does not include meta-analysis.
