Abstract

We propose and analyze several inexact regularized Newton-type methods for finding a global saddle point of convex-concave unconstrained min-max optimization problems. Compared to first-order methods, our understanding of second-order methods for min-max optimization is relatively limited, as obtaining global rates of convergence with second-order information is much more involved. In this paper, we examine how second-order information can be used to speed up extra-gradient methods, even under inexactness. Specifically, we show that the proposed methods generate iterates that remain within a bounded set and that the averaged iterates converge to an \(\epsilon\)-saddle point within \(O(\epsilon^{-2/3})\) iterations in terms of a restricted gap function. This matched the theoretically established lower bound in this context. We also provide a simple routine for solving the subproblem at each iteration, requiring a single Schur decomposition and \(O(\log \log(1/\epsilon))\) calls to a linear system solver in a quasi-upper-triangular system. Thus, our method improves the existing line-search-based second-order min-max optimization methods [Monteiro and Svaiter, 2012, Jiang and Mokhtari, 2022] by shaving off an \(O(\log \log(1/\epsilon))\) factor in the required number of Schur decompositions. Finally, we present a series of numerical experiments on synthetic and real data that demonstrate the efficiency of the proposed methods.

1 Introduction

Let \(\mathbb{R}^m\) and \(\mathbb{R}^n\) be finite-dimensional Euclidean spaces and assume that the function \(f : \mathbb{R}^m \times \mathbb{R}^n \rightarrow \mathbb{R}\) has a bounded and Lipschitz-continuous Hessian. We consider the problem of finding a global saddle point of the following min-max optimization problem:

\[
\min_{x \in \mathbb{R}^m} \max_{y \in \mathbb{R}^n} f(x, y), \tag{1.1}
\]

i.e., a tuple \((x^*, y^*) \in \mathbb{R}^m \times \mathbb{R}^n\) such that

\[
f(x^*, y^*) \leq f(x^*, y) \leq f(x, y^*), \quad \text{for all } x \in \mathbb{R}^m, \ y \in \mathbb{R}^n.
\]

Throughout our paper, we assume that the function \(f(x, y)\) is convex in \(x\) for all \(y \in \mathbb{R}^n\) and concave in \(y\) for all \(x \in \mathbb{R}^m\). This convex-concave setting has been the focus of intense research in optimization, game theory, economics and computer science for several decades now [Von Neumann and Morgenstern,
1953, Dantzig, 1963, Blackwell and Girshick, 1979, Facchinei and Pang, 2007, Ben-Tal et al., 2009], and variants of the problem have recently attracted significant interest in machine learning and data science, with applications in generative adversarial networks (GANs) [Goodfellow et al., 2014, Arjovsky et al., 2017], adversarial learning [Sinha et al., 2018], distributed multi-agent systems [Shamma, 2008], and many other fields; for a wide range of concrete examples, see Facchinei and Pang [2007] and references therein.

Motivated by these applications, several classes of optimization algorithms have been proposed and analyzed for finding a global saddle point of Eq. (1.1) in the convex-concave setting. An important algorithm is the extragradient (EG) method [Korpelevich, 1976, Antipin, 1978, Nemirovski, 2004]. The method’s rate of convergence for smooth and strongly-convex-strongly-concave functions and bilinear functions (i.e., when $f(x, y) = x^\top A y$ for some square, full-rank matrix $A$) was shown to be linear by Korpelevich [1976] and Tseng [1995]. Subsequently, Nemirovski [2004] showed that the method enjoys an $O(\epsilon^{-1})$ convergence guarantee for constrained problems with a bounded domain and a convex-concave function $f$. In unbounded domains, Solodov and Svaiter [1999] generalized EG to the hybrid proximal extragradient (HPE) method which provides a framework for analyzing the iteration complexity of several existing methods, including EG and Tseng’s forward-backward splitting [Tseng, 2000], while Monteiro and Svaiter [2010] provided an $O(\epsilon^{-1})$ guarantee for HPE in both bounded and unbounded domains. In addition to EG, there are other methods that can achieve the same convergence guarantees, such as optimistic gradient descent ascent (OGDA) [Popov, 1980] and dual extrapolation (DE) [Nesterov, 2007]; for a partial survey, see Hsieh et al. [2019] and the references therein. All these methods are order-optimal first-order methods since they match the lower bound of Ouyang and Xu [2021].

Focusing on convex minimization problems for the moment, significant effort has been devoted to developing first-order methods that are characterized by simplicity of implementation and analytic tractability [Nesterov, 1983]. Indeed, it has been recognized that first-order methods are suitable for solving large-scale machine learning problems where low-accuracy solutions may suffice [Sra et al., 2012, Lan, 2020]. However, second-order methods are known to enjoy superior convergence properties over their first-order counterparts, in both theory and practice for many other problems: the accelerated cubic regularized Newton method [Nesterov, 2008] and accelerated Newton proximal extra-gradient method [Monteiro and Svaiter, 2013] converge at a global rate of $O(\epsilon^{-1/3})$ and $\tilde{O}(\epsilon^{-2/7})$ respectively, both exceeding the best possible $O(\epsilon^{-1/2})$ bound for first-order methods [Nemirovski and Yudin, 1983]. Optimal second-order methods with the rate of $O(\epsilon^{-2/7})$ have been recently proposed by Carmon et al. [2022] and Kovalev and Gasnikov [2022], independently. In addition, first-order methods may perform poorly in ill-conditioned problems and are known to be sensitive to the parameter choices in real-world applications in which second-order methods are observed to be more robust [Pilanci and Wainwright, 2017, Roosta-Khorasani and Mahoney, 2019, Berahas et al., 2020].

In the context of convex-concave min-max problems, two separate issues arise: (i) achieving acceleration with second-order information is less tractable analytically; and (ii) acquiring accurate second-order information is computationally very expensive in general. Aiming to address these issues, a line of recent work has generalized classical first-order methods to their higher-order counterparts [Monteiro and Svaiter, 2012, Bullins and Lai, 2022, Jiang and Mokhtari, 2022], where the best known upper iteration bound is $O(\epsilon^{-2/3} \log \log(1/\epsilon))$ [Jiang and Mokhtari, 2022] with a lower bound of $\Omega(\epsilon^{-2/3})$ [Lin and Jordan, 2024]. Closing this gap of log log(1/\epsilon) is mainly of theoretical interest but also has important practical implications because all existing methods require a nontrivial implicit
search scheme at each iteration, and this can be computationally expensive in practice.\footnote{By “implicit,” we mean that the method’s inner-loop subproblem for computing the \(k\)th iterate involves the iterate being updated, leading to an implicit update rule. By contrast, “explicit” means that any inner-loop subproblem for computing the \(k\)th iterate does not involve the new iterate.}

In a similar vein, Huang et al. [2022] extended the cubic regularized Newton method [Nesterov and Polyak, 2006] to convex-concave min-max optimization. Their method has two phases and their guarantees require an error bound condition with a parameter \(0 < \theta \leq 1 [Huang et al., 2022, Assumption 5.1]\). In particular, the rate is linear under a Lipschitz-type condition \((\theta = 1)\) and \(O(\epsilon^{-(1-\theta)/\theta^2})\) under a Hölder-type condition \((\theta \in (0, 1))\). These conditions unfortunately exclude some important problem classes and are hard to verify in general. Another extension of cubic regularized Newton method was provided in Nesterov [2006] and was shown to achieve a global convergence rate of \(O(\epsilon^{-1})\) without assuming any error bound condition.

Finally, it is worth mentioning that existing second-order min-max optimization algorithms require the exact second-order information; as a result, given the implicit nature of the inner loop subproblems involved, the methods’ robustness to inexact information cannot be taken for granted. It is thus natural to ask:

Can we develop explicit second-order min-max optimization algorithms that remain order-optimal even with inexact second-order information?

Our paper offers an affirmative answer to the above question. Inspired by recent advances on variational inequalities (VIs) [Lin and Jordan, 2024], we start by presenting a second-order min-max optimization method with a global rate of \(O(\epsilon^{-2/3})\). Our convergence analysis here is similar to that of Lin and Jordan [2024] although it is simpler in that it exploits the structure of unconstrained min-max optimization problems. More importantly, our work differs from Lin and Jordan [2024] in that the latter requires the exact second-order information and lacks an explicit complexity analysis for inexact subproblem solving.

Thus, the main contribution of our paper is to relax the requirements of existing work by proposing a class of second-order min-max optimization methods that require only inexact second-order information and inexact subproblem solutions. Moreover, our inexact Jacobian regularity condition allows for the use of randomized sampling for solving finite-sum min-max optimization problems. This yields considerable computational savings since the sample size increases gracefully from a very small sample set. We accordingly prove that the inexact methods achieve a global rate of \(O(\epsilon^{-2/3})\) and the subsampled Newton methods achieve the same rate with high probability. Our new subroutine involves solving each subproblem via a single Schur decomposition and \(O(\log \log(1/\epsilon))\) calls to a linear system solver in a quasi-upper-triangular system. As such, the total complexity bound of our method is \(O((m+n)^{\omega} \epsilon^{-2/3} + (m+n)^2 \epsilon^{-2/3} \log \log(1/\epsilon))\) where \(\omega \approx 2.3728\) is the matrix multiplication constant. Experiments conducted on real and synthetic datasets demonstrate the practical efficiency of this method.

To the best of our knowledge, our method is the first second-order min-max optimization method that does not require exact second-order information. This improves on the existing works [Lin and Jordan, 2024, Adil et al., 2022], which present solutions to convex-concave min-max optimization problems with order-optimal iteration complexity of \(\Theta(\epsilon^{-2/3})\), but either require an exact solution of an inner explicit subproblem or lack a characterization of the complexity of solving each subproblem. Indeed, Adil et al. [2022] showed that solving each subproblem requires a single Schur decomposition and \(O(\log(1/\epsilon))\) calls to a linear system solver in a quasi-upper-triangular system. Our work is also related to a recent literature on the line-search-based methods [Monteiro and Svaiter, 2012, Bullins and Lai, 2022,

Experiments conducted on real and synthetic datasets demonstrate the practical efficiency of this method.

To the best of our knowledge, our method is the first second-order min-max optimization method that does not require exact second-order information. This improves on the existing works [Lin and Jordan, 2024, Adil et al., 2022], which present solutions to convex-concave min-max optimization problems with order-optimal iteration complexity of \(\Theta(\epsilon^{-2/3})\), but either require an exact solution of an inner explicit subproblem or lack a characterization of the complexity of solving each subproblem. Indeed, Adil et al. [2022] showed that solving each subproblem requires a single Schur decomposition and \(O(\log(1/\epsilon))\) calls to a linear system solver in a quasi-upper-triangular system. Our work is also related to a recent literature on the line-search-based methods [Monteiro and Svaiter, 2012, Bullins and Lai, 2022,
Jiang and Mokhtari, 2022, Lin and Jordan, 2023]. Differing from these methods, our method is explicit and achieves an order-optimal iteration complexity: specifically, in terms of complexity bound guarantees, our method slightly outperforms the best known line-search-based method [Jiang and Mokhtari, 2022] that achieves the bound of $O((m + n)^{2/3} \epsilon^{-2/3} \log \log(1/\epsilon))$.

1.1 Related Work

Our work comes amid a surge of interest in optimization algorithms for a large class of emerging min-max optimization problems. For brevity, we will focus on convex-concave settings and leave other settings out of the discussion; see Lin et al. [2020, Section 2] for a more detailed presentation.

Historically, a concrete instantiation of the convex-concave min-max optimization problem is the solution of $\min_{x \in \Delta^m} \max_{y \in \Delta^n} x^\top Ay$ for $A \in \mathbb{R}^{m \times n}$ over the simplices $\Delta^m$ and $\Delta^n$. Spurred by the von Neumann’s theorem [Neumann, 1928], this problem provided the initial impetus for min-max optimization. Sion [1958] generalized von Neumann’s result from bilinear cases to convex-concave cases and triggered a line of research on algorithms for convex-concave min-max optimization [Korpelevich, 1976, Nemirovski, 2004, Nesterov, 2007, Nedić and Ozdaglar, 2009, Mokhtari et al., 2020]. A notable result is that gradient descent ascent (GDA) with diminishing stepsizes can find an $\epsilon$-global saddle point within $O(\epsilon^{-2})$ iterations if the gradients are bounded over the feasible sets [Nedić and Ozdaglar, 2009].

Recent years have witnessed progress on the analysis of first-order min-max optimization algorithms in bilinear cases and convex-concave cases. In a bilinear case, Daskalakis et al. [2018] proved the convergence of OGDA to a neighborhood of a global saddle point. Liang and Stokes [2019] used a dynamical system approach to establish the linear convergence of OGDA for the special case when the matrix $A$ is square and full rank. Mokhtari et al. [2020a] have revisited proximal point method and proposed an unified framework for achieving the sharpest convergence rates of both EG and OGDA. In the convex-concave case, Nemirovski [2004] demonstrated that EG finds an $\epsilon$-global saddle point within $O(\epsilon^{-1})$ iterations when the feasible sets are convex and compact. The same convergence guarantee was extended to unbounded feasible sets [Monteiro and Svaiter, 2010, 2011] using the HPE method with different optimality criteria. Nesterov [2007] and Tseng [2008] proposed several new algorithms and refined convergence analysis with the same convergence guarantee. Abernethy et al. [2021] presented a Hamiltonian gradient descent method with last-iterate convergence under a “sufficiently bilinear” condition. Focusing on special min-max optimization problems with $f(x, y) = g(x) + x^\top Ay - h(y)$, Chambolle and Pock [2011] introduced a primal-dual hybrid gradient method that converges to a global saddle point at the rate of $O(\epsilon^{-1})$ when the functions $g$ and $h$ are simple and convex. Nesterov [2005] proved a smoothing technique and proved that his algorithm achieves better dependence on problem parameters for convex and compact constraint sets. He and Monteiro [2016] and Koloskosi and Monteiro [2017] proved that such a result still holds true for unbounded feasible sets and non-Euclidean metrics. Moreover, Chen et al. [2014] developed optimal algorithms for solving min-max optimization problems with $f(x, y) = g(x) + x^\top Ay - h(y)$ even when only noisy gradients are available.

Compared to first-order methods, there has been less research on second-order methods for min-max optimization problems with global convergence rate guarantee. In particular, we are aware of two research thrusts [Monteiro and Svaiter, 2012, Bullins and Lai, 2022, Jiang and Mokhtari, 2022, Huang et al., 2022, Adil et al., 2022, Lin and Jordan, 2023, 2024]. Our results contribute to this landscape by proposing the first explicit method that achieves the order-optimal iteration complexity of $O(\epsilon^{-2/3})$ and a tight complexity of $O((m + n)^{2/3} \epsilon^{-2/3} + (m + n)^2 \epsilon^{-2/3} \log \log(1/\epsilon))$. As far as we are aware, the complexity bound guarantees of Algorithms 2 and 3 cannot be realized by other existing
second-order min-max optimization methods with exact second-order information requirements.

1.2 Notation and Organization

We use bold lower-case letters to denote vectors, as in \( \mathbf{x}, \mathbf{y}, \mathbf{z} \). For a function \( f(\cdot) : \mathbb{R}^n \to \mathbb{R} \), we let \( \nabla f(\mathbf{z}) \) denote the gradient of \( f \) at \( \mathbf{z} \). For a function \( f(\cdot, \cdot) : \mathbb{R}^m \times \mathbb{R}^n \to \mathbb{R} \) of two variables, \( \nabla_x f(\mathbf{x}, \mathbf{y}) \) or \( \nabla_y f(\mathbf{x}, \mathbf{y}) \) to denote the partial gradient of \( f \) with respect to the first variable or the second variable at the point \( (\mathbf{x}, \mathbf{y}) \). We use \( \nabla f(\mathbf{x}, \mathbf{y}) \) to denote the gradient at \( (\mathbf{x}, \mathbf{y}) \) where \( \nabla f(\mathbf{x}, \mathbf{y}) = (\nabla_x f(\mathbf{x}, \mathbf{y}), \nabla_y f(\mathbf{x}, \mathbf{y})) \) and \( \nabla^2 f(\mathbf{x}, \mathbf{y}) \) to denote the full Hessian at \( (\mathbf{x}, \mathbf{y}) \). We write \( \|\mathbf{x}\| \) for its \( \ell_2 \)-norm. Finally, we use \( O(\cdot), \tilde{O}(\cdot) \) to hide absolute constants which do not depend on problem parameters, and \( \tilde{O}(\cdot), \tilde{\Omega}(\cdot) \) to hide absolute constants and additional log factors.

The remainder of the paper is organized as follows. In Section 2, we present the setup of min-max optimization and provide the definitions and optimality criteria. In Section 3, we present an explicit yet conceptual second-order min-max optimization method and prove that it achieves an order-optimal iteration complexity of \( \Theta(\epsilon^{-2/3}) \). In Section 4, we propose a class of second-order min-max optimization methods with inexact second-order information and inexact subproblem solving, and we provide a crisp characterization of the complexity of solving each subproblem. In addition, we propose a set of subsampled Newton methods for solving the finite-sum min-max optimization problems. In Section 5, we present the results of experiments on real and synthetic datasets that demonstrate the practical efficiency of the proposed methods.

2 Preliminaries

We present the setup of min-max optimization under study, and we provide the definitions for functions as well as optimality criteria considered. In this regard, the regularity conditions that we impose for the function \( f : \mathbb{R}^{m+n} \to \mathbb{R} \) are as follows:

Definition 2.1 A function \( f \) is \( \rho \)-Hessian Lipschitz if \( \|\nabla^2 f(\mathbf{z}) - \nabla^2 f(\mathbf{z}')\| \leq \rho \|\mathbf{z} - \mathbf{z}'\| \) for all \( \mathbf{z}, \mathbf{z}' \in \mathbb{R}^n \).

Definition 2.2 A differentiable function \( f \) is convex-concave if

\[
\begin{align*}
    f(\mathbf{x}', \mathbf{y}) & \geq f(\mathbf{x}, \mathbf{y}) + (\mathbf{x}' - \mathbf{x})^\top \nabla_x f(\mathbf{x}, \mathbf{y}), & \text{for } \mathbf{x}', \mathbf{x} \in \mathbb{R}^m \text{ and any fixed } \mathbf{y} \in \mathbb{R}^n, \\
    f(\mathbf{x}, \mathbf{y}') & \leq f(\mathbf{x}, \mathbf{y}) + (\mathbf{y}' - \mathbf{y})^\top \nabla_y f(\mathbf{x}, \mathbf{y}), & \text{for } \mathbf{y}', \mathbf{y} \in \mathbb{R}^n \text{ and any fixed } \mathbf{x} \in \mathbb{R}^m.
\end{align*}
\]

We also define the notion of global saddle points for the problem in Eq. (1.1).

Definition 2.3 A point \( \mathbf{z}^* = (\mathbf{x}^*, \mathbf{y}^*) \in \mathbb{R}^m \times \mathbb{R}^n \) is a global saddle point of a function \( f(\cdot, \cdot) \) if \( f(\mathbf{x}^*, \mathbf{y}) \leq f(\mathbf{x}^*, \mathbf{y}^*) \leq f(\mathbf{x}, \mathbf{y}^*) \) for all \( \mathbf{x} \in \mathbb{R}^m \) and \( \mathbf{y} \in \mathbb{R}^n \).

Throughout this paper, we assume that the following conditions are satisfied.

Assumption 2.4 The function \( f(\mathbf{x}, \mathbf{y}) \) is continuously differentiable and convex-concave, and at least one global saddle point of \( f(\mathbf{x}, \mathbf{y}) \) exists.

Assumption 2.5 The function \( f(\mathbf{x}, \mathbf{y}) \) is \( \rho \)-Hessian Lipschitz.
The existence of a global saddle point \( z^* = (x^*, y^*) \) under Assumption 2.4 guarantees that \( f(x^*, y) \leq f(x^*, y^*) \leq f(x, y^*) \) for all \( x \in \mathbb{R}^m \) and \( y \in \mathbb{R}^n \). Thus, we can adopt a restricted gap function [Nesterov, 2007] to provide a performance measure for the optimality of \( \hat{z} = (\hat{x}, \hat{y}) \) in the unconstrained convex-concave setting.²

**Definition 2.6** The restricted gap function is defined by

\[
gap(\hat{z}, \beta) = \max_{y : \|y - y^*\| \leq \beta} f(\hat{x}, y) - \min_{x : \|x - x^*\| \leq \beta} f(x, \hat{y})
\]

where \( \beta \) is sufficiently large such that \( \|\hat{z} - z^*\| \leq \beta \). Clearly, we have \( \gap(\hat{z}, \beta) \geq 0 \) since \( f(x^*, \hat{y}) \leq f(\hat{x}, y^*) \) must hold true.

**Definition 2.7** A point \( \hat{z} = (\hat{x}, \hat{y}) \) is an \( \epsilon \)-global saddle point of a convex-concave function \( f(\cdot, \cdot) \) if \( \gap(\hat{z}, \beta) \leq \epsilon \). If \( \epsilon = 0 \), it is a global saddle point.

In our method, we denote the \( k \)th iterate by \((x_k, y_k)\) and we define the averaged (ergodic) iterates by \((\bar{x}_k, \bar{y}_k)\). In particular, given a sequence of weights \( \{\lambda_k\}_{k=1}^T \), we let

\[
\bar{x}_k = \frac{1}{\sum_{i=1}^k \lambda_i} \left( \sum_{i=1}^k \lambda_i x_i \right), \quad \bar{y}_k = \frac{1}{\sum_{i=1}^k \lambda_i} \left( \sum_{i=1}^k \lambda_i y_i \right).
\]

(2.1)

In our convergence analysis, we define the vector \( z = (x, y) \in \mathbb{R}^{m+n} \) and the operator \( F : \mathbb{R}^{m+n} \mapsto \mathbb{R}^{m+n} \) as follows,

\[
F(z) = \begin{bmatrix} \nabla_x f(x, y) \\ -\nabla_y f(x, y) \end{bmatrix}.
\]

(2.2)

Accordingly, the Jacobian of \( F \) is defined as follows (note that \( DF \) is asymmetric in general),

\[
DF(z) = \begin{bmatrix} \nabla_{xx} f(x, y) & \nabla_{xy}^2 f(x, y) \\ -\nabla_{yx}^2 f(x, y) & -\nabla_{yy} f(x, y) \end{bmatrix} \in \mathbb{R}^{(m+n) \times (m+n)}.
\]

(2.3)

In the following lemma, we provide the properties of the operator \( F \) in Eq. (2.2) and its Jacobian \( DF \) in Eq. (2.3) under Assumption 2.4 and 2.5. We note that most of the results in the following lemma are well known [Nemirovski, 2004] so we omit their proofs.

**Lemma 2.8** Let \( F(\cdot) \) and \( DF(\cdot) \) be defined as above and Assumptions 2.4 and 2.5 hold true. Then, we have

(a) \( F \) is monotone, i.e., \((z - z')^\top (F(z) - F(z')) \geq 0\).

(b) \( DF \) is \( \rho \)-Lipschitz continuous, i.e., \( \|DF(z) - DF(z')\| \leq \rho \|z - z'\| \).

(c) \( F(z^*) = 0 \) for any global saddle point \( z^* \in \mathbb{R}^{m+n} \) of the function \( f(\cdot, \cdot) \).

²The restricted gap is also related to the classical Nikaidō-Isoda function [Nikaidō and Isoda, 1955] defined for a class of noncooperative convex games in a more general setting.
Proof. Note that (a) and (c) were proven in Nemirovski [2004], and it suffices to prove (b). By using the definition of $DF(\cdot)$ in Eq. (2.3), we have

$$(DF(z) - DF(z'))h = \left[ I_m - I_n \right] (\nabla^2 f(z) - \nabla^2 f(z'))h.$$  \hspace{1cm} (2.4)

This implies that $\| (DF(z) - DF(z'))h \| = \| (\nabla^2 f(z) - \nabla^2 f(z'))h \|$. Thus, we have

$$\| DF(z) - DF(z') \| = \sup_{h \neq 0} \left\{ \frac{|(DF(z) - DF(z'))h|}{\|h\|} \right\} = \sup_{h \neq 0} \left\{ \frac{\| \nabla^2 f(z) - \nabla^2 f(z') \|}{\|h\|} \right\}.$$  

This equality together with Assumption 2.5 implies the desired result in (b). \hfill \Box

Before proceeding to our algorithmic framework and convergence analysis, we present the following well-known result which will be used in the subsequent analysis. Given its importance, we provide the proof for completeness.

**Proposition 2.9** Let $(\bar{x}_k, \bar{y}_k)$ and $F(\cdot)$ be defined in Eq. (2.1) and (2.2). Then, under Assumption 2.4, the following statement holds true,

$$f(\bar{x}_k, \bar{y}_k) - f(x, \bar{y}_k) \leq \frac{1}{\sum_{i=1}^{k} \lambda_i} \left( \sum_{i=1}^{k} \lambda_i (z_i - z)^\top F(z_i) \right).$$

*Proof.* Using the definition of the operator $F(\cdot)$ in Eq. (2.2), we have

$$\sum_{i=1}^{k} \lambda_i (z_i - z)^\top F(z_i) = \sum_{i=1}^{k} \lambda_i ((x_i - x)^\top \nabla_x f(x_i, y_i) - (y_i - y)^\top \nabla_y f(x_i, y_i)).$$

Note that Assumption 2.4 implies that the function $f(x, y)$ is a convex function of $x$ for any $y \in \mathbb{R}^n$ and a concave function of $y$ for any $x \in \mathbb{R}^m$. Then, we have

$$(x_i - x)^\top \nabla_x f(x_i, y_i) \geq f(x_i, y_i) - f(x, y_i),$$

$$(y_i - y)^\top \nabla_y f(x_i, y_i) \leq f(x_i, y_i) - f(x_i, y).$$

Putting these pieces together with $\lambda_i > 0$ for all $1 \leq i \leq k$ yields that

$$\frac{1}{\sum_{i=1}^{k} \lambda_i} \left( \sum_{i=1}^{k} \lambda_i (z_i - z)^\top F(z_i) \right) \geq \frac{1}{\sum_{i=1}^{k} \lambda_i} \left( \sum_{i=1}^{k} \lambda_i (f(x_i, y) - f(x, y_i)) \right). \hspace{1cm} (2.5)$$

Using the definition of $(\bar{x}_k, \bar{y}_k)$ in Eq. (2.1) and that $f$ is convex-concave, we have

$$\frac{1}{\sum_{i=1}^{k} \lambda_i} \left( \sum_{i=1}^{k} \lambda_i f(x_i, y) \right) \geq f(\bar{x}_k, y), \quad \frac{1}{\sum_{i=1}^{k} \lambda_i} \left( \sum_{i=1}^{k} \lambda_i f(x, y_i) \right) \leq f(x, \bar{y}_k).$$

Plugging these two inequalities in Eq. (2.5), we conclude the desired inequality. \hfill \Box
Algorithm 1 Newton-MinMax($z_0$, $\rho$, $T$)

Input: initial point $z_0$, Lipschitz parameter $\rho$ and iteration number $T \geq 1$.
Initialization: set $\hat{z}_0 = z_0$.
for $k = 0, 1, 2, \ldots, T - 1$ do
    STEP 1: If $z_k$ is a global saddle point of the problem in Eq. (1.1), then stop.
    STEP 2: Compute an exact solution $\Delta z_k$ of the subproblem in Eq. (3.1).
    STEP 3: Compute $\lambda_{k+1} > 0$ such that
            \[ \frac{1}{33} \leq \lambda_{k+1} \rho \| \Delta z_k \| \leq \frac{1}{13}. \]
    STEP 4: Compute $z_{k+1} = \hat{z}_k + \Delta z_k$.
    STEP 5: Compute $\hat{z}_{k+1} = \hat{z}_k - \lambda_{k+1} F(z_{k+1})$.
end for
Output: $\bar{z}_T = \frac{1}{\sum_{k=1}^{T} \lambda_k} \left( \sum_{k=1}^{T} \lambda_k z_k \right)$.

3 Conceptual Algorithm and Convergence Analysis

As a warm-up, we describe the scheme of Newton-MinMax which is a second-order version of the method in Lin and Jordan [2024] for min-max optimization and which yields an optimal global rate of $\Theta(\epsilon^{-2/3})$. We emphasize that Newton-MinMax is a conceptual algorithmic framework in the sense that it requires exact second-order information and requires the cubic regularized subproblem to be solved exactly.

3.1 Algorithmic scheme

We summarize our second-order method, which we call Newton-MinMax($z_0$, $\rho$, $T$), in Algorithm 1 where $z_0 = (x_0, y_0) \in \mathbb{R}^m \times \mathbb{R}^n$ is an initial point, $\rho > 0$ is a Lipschitz constant for the Hessian of the function $f$ and $T \geq 1$ is an iteration number.

Our method is a generalization of first-order extragradient method. Indeed, the $k$th iteration consists of two important algorithmic components:

- **Gradient update:** Compute $\Delta z_k \in \mathbb{R}^m \times \mathbb{R}^n$ such that it is an exact solution of the nonlinear equation problem given by
  \[ F(\hat{z}_k) + DF(\hat{z}_k) \Delta z_k + 6\rho \| \Delta z_k \| \Delta z_k = 0. \] (3.1)
  Compute $z_{k+1} = \hat{z}_k + \Delta z_k$.

- **Extragradient update:** Compute $\hat{z}_{k+1} = \hat{z}_k - \lambda_{k+1} F(z_{k+1})$.

As suggested by Lin and Jordan [2024], we choose to update $\lambda_k$ in an adaptive manner and then prove that our method can achieve an order-optimal iteration complexity of $O(\epsilon^{-2/3})$ under Assumptions 2.4 and 2.5. Intuitively, such a strategy makes sense; indeed, $\lambda_k$ is the step size and would be better to increase as the iterate $z_k$ approaches the set of global saddle points where the value of $\| \Delta z_k \|$ measures the closeness. From a practical viewpoint, Algorithm 1 serves as an alternative to the current pipeline of line-search-based methods – which it simplifies by removing the need for an implicit binary search.

3.2 Convergence analysis

We provide our results on the iteration complexity of Algorithm 1 in the following theorem.
Theorem 3.1 Suppose that Assumptions 2.4 and 2.5 hold. Then, the sequence of iterates generated by Algorithm 1 is bounded and, in addition
\[
gap(\bar{z}_T, \beta) \leq \frac{2112 \sqrt{3} \rho \| z_0 - z^* \|^2}{T^{3/2}},
\]
where \( z^* = (x^*, y^*) \) is a global saddle point, \( \rho > 0 \) is defined as in Assumption 2.5, and \( \beta = 7 \| z_0 - z^* \| \). As such, Algorithm 1 achieves an \( \epsilon \)-global saddle point solution within \( O(\epsilon^{-2/3}) \) iterations.

Remark 3.2 Theorem 3.1 shows that Algorithm 1 has achieved the lower bound established in the literature for second-order VI methods [Lin and Jordan, 2024] and is thus order-optimal in this regard; in addition, it improves on the state-of-the-art bounds of Monteiro and Svaiter [2012], Bullins and Lai [2022], Jiang and Mokhtari [2022] by shaving off all logarithmic factors.

We define a Lyapunov function for Algorithm 1: \( \mathcal{E}_t = \frac{1}{2} \| \bar{z}_t - z_0 \|^2 \) and use it to prove technical results that pertain to the convergence of Algorithm 1. The first lemma gives us a key descent inequality.

Lemma 3.3 Suppose that Assumptions 2.4 and 2.5 hold. Then
\[
\sum_{k=1}^{t} \lambda_k (z_k - z)^\top F(z_k) \leq \mathcal{E}_0 - \mathcal{E}_t + (z_0 - \hat{z}_t)^\top (z_0 - z) - \frac{1}{2t} \left( \sum_{k=1}^{t} \| z_k - \hat{z}_{k-1} \|^2 \right).
\]

Proof. Using the definition of the Lyapunov function, we have
\[
\mathcal{E}_k - \mathcal{E}_{k-1} = \frac{1}{2} \| \hat{z}_k - z_0 \|^2 - \frac{1}{2} \| \bar{z}_k - z_0 \|^2 = (\hat{z}_k - \hat{z}_{k-1})^\top (\hat{z}_k - z_0) - \frac{1}{2} \| \bar{z}_k - \hat{z}_{k-1} \|^2.
\]
Plugging \( \hat{z}_k = \hat{z}_{k-1} - \lambda_k F(z_k) \) into Eq. (3.2) yields
\[
\mathcal{E}_k - \mathcal{E}_{k-1} \leq \lambda_k (z_0 - \hat{z}_k)^\top F(z_k) - \frac{1}{2} \| \bar{z}_k - \hat{z}_{k-1} \|^2
\]
\[
= \lambda_k (z_0 - z)^\top F(z_k) + \lambda_k (z - z_k)^\top F(z_k) + \lambda_k (z_k - \hat{z}_k)^\top F(z_k) - \frac{1}{2} \| \bar{z}_k - \hat{z}_{k-1} \|^2.
\]
Summing up the above inequality over \( k = 1, 2, \ldots, t \) yields
\[
\sum_{k=1}^{t} \lambda_k (z_k - z)^\top F(z_k) \leq \mathcal{E}_0 - \mathcal{E}_t
\]
\[
+ \sum_{k=1}^{t} \lambda_k (z_0 - z)^\top F(z_k) + \sum_{k=1}^{t} \lambda_k (z_k - \hat{z}_k)^\top F(z_k) - \frac{1}{2} \| \bar{z}_k - \hat{z}_{k-1} \|^2.
\]

By using the relationship \( \hat{z}_k = \hat{z}_{k-1} - \lambda_k F(z_k) \) again, we have
\[
\mathcal{I} = \sum_{k=1}^{t} \lambda_k (z_0 - z)^\top F(z_k) = \sum_{k=1}^{t} (\hat{z}_{k-1} - \hat{z}_k)^\top (z_0 - z) = (\hat{z}_0 - \hat{z}_t)^\top (z_0 - z).
\]
In Algorithm 1, we compute \( \Delta z_k \) as an exact solution of the nonlinear equation problem given by
\[
F(\hat{z}_k) + DF(\hat{z}_k) \Delta z_k + 6\rho \| \Delta z_k \| \Delta z_k = 0.
\]
Using $z_k = \hat{z}_{k-1} + \Delta z_{k-1}$ and Lemma 2.8, we have
\[
\|F(z_k) - F(\hat{z}_{k-1}) - \frac{\rho}{2} \|\Delta z_{k-1}\|^2 \|z_k - \hat{z}_k\| - 6\rho \|\Delta z_{k-1}\| (z_k - \hat{z}_k) \Delta z_{k-1} \leq \frac{\rho}{2} \|\Delta z_{k-1}\|^2
\]
so it suffices to decompose $(z_k - \hat{z}_k)^T F(z_k)$ and bound this term using Eq. (3.5) and (3.6). Indeed, to that end, we have
\[
(z_k - \hat{z}_k)^T F(z_k) \leq \frac{\rho}{2} \|\Delta z_{k-1}\|^2 \|z_k - \hat{z}_k\| - 6\rho \|\Delta z_{k-1}\| (z_k - \hat{z}_k)^T \Delta z_{k-1}
\]
\[
\leq \frac{\rho}{2} \left( \|\Delta z_{k-1}\|^2 + \|\Delta z_{k-1}\|^2 \|\hat{z}_{k-1} - \hat{z}_k\| \right) - 6\rho \|\Delta z_{k-1}\| (z_k - \hat{z}_k)^T \Delta z_{k-1}
\]
Note that we have $(z_k - \hat{z}_k)^T \Delta z_{k-1} \geq \|\Delta z_{k-1}\|^2 - \|\Delta z_{k-1}\| \|\hat{z}_{k-1} - \hat{z}_k\|$. This implies
\[
\|\Delta z_{k-1}\| (z_k - \hat{z}_k)^T \Delta z_{k-1} \geq \|\Delta z_{k-1}\|^3 - \|\Delta z_{k-1}\|^2 \|\hat{z}_{k-1} - \hat{z}_k\|
\]
Putting these pieces together yields
\[
(z_k - \hat{z}_k)^T F(z_k) \leq \frac{13\rho}{2} \|\Delta z_{k-1}\|^2 \|\hat{z}_{k-1} - \hat{z}_k\| - \frac{11\rho}{2} \|\Delta z_{k-1}\|^3
\]
Since $\frac{1}{13} \leq \lambda_k \rho \|\Delta z_{k-1}\| \leq \frac{1}{13}$ for all $k \geq 1$, we have
\[
\begin{align*}
\mathrm{II} & \leq \sum_{k=1}^{t} \left( \frac{13\lambda_k \rho}{2} \|\Delta z_{k-1}\|^2 \|\hat{z}_{k-1} - \hat{z}_k\| - \frac{1}{2} \|\hat{z}_{k-1} - \hat{z}_k\|^2 \right) \\
& \leq \sum_{k=1}^{t} \left( \frac{1}{2} \|\Delta z_{k-1}\| \|\hat{z}_{k-1} - \hat{z}_k\| - \frac{1}{2} \|\hat{z}_{k-1} - \hat{z}_k\|^2 - \frac{1}{6} \|\Delta z_{k-1}\|^2 \right) \\
& \leq \sum_{k=1}^{t} \left( \max_{\eta \geq 0} \left\{ \frac{1}{2} \|\Delta z_{k-1}\| \eta - \frac{1}{2} \eta^2 \right\} - \frac{1}{6} \|\Delta z_{k-1}\|^2 \right) = -\frac{1}{24} \left( \sum_{k=1}^{t} \|\Delta z_{k-1}\|^2 \right)
\end{align*}
\]
Plugging Eq. (3.4) and (3.7) into Eq. (3.3) and using $\hat{z}_0 = z_0$ and $\Delta z_{k-1} = z_k - \hat{z}_{k-1}$ yields
\[
\sum_{k=1}^{t} \lambda_k (z_k - z)^T F(z_k) \leq E_0 - E_t + (z_0 - \hat{z}_t)^T (z_0 - z) - \frac{1}{24} \left( \sum_{k=1}^{t} \|z_k - \hat{z}_{k-1}\|^2 \right)
\]
This completes the proof.
\[
\square
\]

**Lemma 3.4** Suppose that Assumptions 2.4 and 2.5 hold. Then, we have $\|\hat{z}_t - z_0\| \leq 2\|z_0 - z^*\|$ and
\[
\sum_{k=1}^{t} \lambda_k (z_k - z)^T F(z_k) \leq \frac{1}{2} \|z_0 - z\|^2, \quad \sum_{k=1}^{t} \|z_k - \hat{z}_{k-1}\|^2 \leq 12\|z_0 - z^*\|^2,
\]
where $z \in \mathbb{R}^{m+n}$ is any point and $z^*$ is a global saddle point.

**Proof.** Since $\hat{z}_0 = z_0$, we have
\[
E_0 - E_t + (z_0 - \hat{z}_t)^T (z_0 - z) \leq -\frac{1}{2} \|\hat{z}_t - z_0\|^2 + \frac{1}{2} \|\hat{z}_t - z_0\|^2 + \frac{1}{2} \|z_0 - z\|^2 = \frac{1}{2} \|z_0 - z\|^2.
\]
This together with Lemma 3.3 yields
\[ \sum_{k=1}^{t} \lambda_k (z_k - z)^\top F(z_k) \leq \frac{1}{2} \|z_0 - z\|^2 - \frac{1}{24} \left( \sum_{k=1}^{t} \|z_k - \hat{z}_{k-1}\|^2 \right) \leq \frac{1}{2} \|z_0 - z\|^2. \]

Since \( z^* \) is a global saddle point, we have \( (z_k - z^*)^\top F(z_k) \geq 0 \) for all \( k \geq 1 \). Then, we have
\[ \sum_{k=1}^{t} \|z_k - \hat{z}_{k-1}\|^2 \leq 12 \|z_0 - z^*\|^2. \]

Further, Lemma 3.3 with \( z = z^* \) implies
\[ E_0 - E_t + (z_0 - \hat{z}_t)^\top (z_0 - z^*) \geq \sum_{k=1}^{t} \lambda_k (z_k - z^*)^\top F(z_k) + \frac{1}{24} \left( \sum_{k=1}^{t} \|z_k - \hat{z}_{k-1}\|^2 \right) \geq 0. \]

Using Young’s inequality, we have
\[ 0 \leq -\frac{1}{2} \|\hat{z}_t - z_0\|^2 + \frac{1}{4} \|\hat{z}_t - z_0\|^2 + \|z_0 - z^*\|^2 = -\frac{1}{4} \|\hat{z}_t - z_0\|^2 + \|z_0 - z^*\|^2. \]

This completes the proof. \( \square \)

**Lemma 3.5** Suppose that Assumptions 2.4 and 2.5 hold. Then, for every integer \( T \geq 1 \), we have
\[ \sum_{k=1}^{T} \lambda_k \geq \frac{T^{\frac{4}{3}}}{66 \sqrt{3 \rho} \|z_0 - z^*\|}, \]

where \( z^* \) is a global saddle point.

**Proof.** Without loss of generality, we assume that \( z_0 \neq z^* \). Then, Lemma 3.4 implies
\[ \sum_{k=1}^{t} (\lambda_k)^{-2} \left( \frac{1}{33 \rho} \right)^2 \leq \sum_{k=1}^{t} (\lambda_k)^{-2} (\lambda_k \|z_k - \hat{z}_{k-1}\|)^2 = \sum_{k=1}^{t} \|z_k - \hat{z}_{k-1}\|^2 \leq 12 \|z_0 - z^*\|^2. \]

By the Hölder inequality, we have
\[ \sum_{k=1}^{t} 1 = \sum_{k=1}^{t} (\lambda_k)^{-2} (\lambda_k)^{\frac{2}{3}} \leq \left( \sum_{k=1}^{t} (\lambda_k)^{-2} \right)^{\frac{1}{3}} \left( \sum_{k=1}^{t} \lambda_k \right)^{\frac{2}{3}}. \]

Putting these pieces together yields
\[ t \leq \left( 66 \sqrt{3 \rho} \|z_0 - z^*\| \right)^{\frac{2}{3}} \left( \sum_{k=1}^{t} \lambda_k \right)^{\frac{2}{3}}. \]

Letting \( t = T \) and rearranging yields the desired result. \( \square \)
Proof of Theorem 3.1 By Lemma 3.4, we have
\[ \|z_{k+1} - \hat{z}_k\|^2 \leq 12\|z_0 - z^*\|^2, \quad \|\hat{z}_k - z_0\| \leq 2\|z_0 - z^*\|, \quad \text{for all } k \geq 0. \]
This implies that \( \|z_k - z_0\| \leq 6\|z_0 - z^*\| \) for all \( k \geq 0 \). Putting these pieces together yields that both \( \{z_k\}_{k \geq 0} \) and \( \{\hat{z}_k\}_{k \geq 0} \) are bounded by a constant; indeed, we have \( \|\hat{z}_k - z^*\| \leq 3\|z_0 - z^*\| \leq \beta \) and \( \|z_k - z^*\| \leq 7\|z_0 - z^*\| = \beta \). For every integer \( T \geq 1 \), Lemma 3.4 also implies
\[ \sum_{k=1}^{T} \lambda_k (z_k - z)^\top F(z_k) \leq \frac{1}{\beta} \|z_0 - z\|^2. \]
By Proposition 2.9, we have
\[ f(\bar{x}_T, y) - f(x, \bar{y}_T) \leq \frac{1}{\sum_{k=1}^{T} \lambda_k} \left( \sum_{k=1}^{T} \lambda_k (z_k - z)^\top F(z_k) \right). \]
Putting these pieces together yields
\[ f(\bar{x}_T, y) - f(x, \bar{y}_T) \leq \frac{1}{2(\sum_{k=1}^{T} \lambda_k)} \|z_0 - z\|^2. \]
This together with Lemma 3.5 yields
\[ f(\bar{x}_T, y) - f(x, \bar{y}_T) \leq \frac{33\sqrt{7}\rho\|z_0 - z^*\|\|z_0 - z\|^2}{T^{3/2}}. \]
Since \( \|z_k - z^*\| \leq \beta \) for all \( k \geq 0 \), we have \( \|\bar{z}_T - z^*\| \leq \beta \). By the definition of the restricted gap function, we have
\[ \text{gap}(\bar{z}_T, \beta) \leq \frac{33\sqrt{7}\rho\|z_0 - z^*\|((\|z_0 - z^*\| + \beta)^2)}{T^{3/2}} = \frac{2112\sqrt{7}\rho\|z_0 - z^*\|^3}{T^{3/2}}. \]
Therefore, we conclude from the above inequality that there exists some \( T > 0 \) such that the output \( \bar{z} = \text{Newton-MinMax}(z_0, \rho, T) \) satisfies that \( \text{gap}(\bar{z}, \beta) \leq \epsilon \) and the total number of iterations is bounded by \( O(\rho^{2/3}\|z_0 - z^*\|^2\epsilon^{-2/3}) \). \( \square \)

Remark 3.6 Although Algorithm 1 is conceptual, it forms the basis for the material in the next section, where we relax the strong requirements of Algorithm 1 and propose a class of second-order min-max optimization methods that require only inexact second-order information and inexact subproblem solutions.

4 Inexact Algorithm and Complexity Analysis

Building on the conceptual algorithm of the previous section, we present the Inexact-Newton-MinMax scheme, and we provide a global convergence guarantee in terms of the number of iterations required until convergence. Our inexact Jacobian regularity condition is inspired by Xu et al. [2020] and it allows for the use of randomized sampling for solving finite-sum min-max optimization problems. Our subroutine, which is inspired by Adil et al. [2022], can solve each subproblem using a single Schur decomposition and \( O(\log \log(1/\epsilon)) \) calls to a linear system solver in a quasi-upper-triangular system.
Algorithm 2 Inexact-Newton-MinMax($z_0$, $\rho$, $T$)

| Input: initial point $z_0$, Lipschitz parameter $\rho$ and iteration number $T \geq 1$. |
| Initialization: set $\hat{z}_0 = z_0$ as well as $\kappa_J > 0$, $0 < \kappa_m < \min\{1, \frac{\rho}{T}\}$ and $0 \leq \tau_0 < \frac{\rho}{T}$. |
| for $k = 0, 1, 2, \ldots, T - 1$ do |
|    STEP 1: If $z_k$ is a global saddle point of the problem in Eq. (1.1), then stop. |
|    STEP 2: Compute an inexact solution $\Delta z_k$ of the subproblem |
|    $F(\hat{z}_k) + J(\hat{z}_k) \Delta z_k + 6\rho \|\Delta z_k\| \Delta z_k = 0$. (4.1) |
|    such that Condition 4.1 and 4.2 hold true with a proper choice of $\tau_k \geq 0$. |
|    STEP 3: Compute $\lambda_{k+1} > 0$ such that $\frac{1}{3\rho} \leq \lambda_{k+1} \|\Delta z_k\| \leq \frac{1}{17}$. |
|    STEP 4: Compute $z_{k+1} = \hat{z}_k + \Delta z_k$. |
|    STEP 5: Compute $\hat{z}_{k+1} = \hat{z}_k - \lambda_{k+1} F(z_{k+1})$. |
| end for |
| Output: $\bar{z}_T = \frac{1}{\sum_{k=1}^{T} \lambda_k} \left( \sum_{k=1}^{T} \lambda_k z_k \right)$. |

4.1 Algorithmic scheme

We summarize our inexact second-order method, which we call Inexact-Newton-MinMax($z_0$, $\rho$, $T$), in Algorithm 2 where $z_0$ is an initial point, $\rho > 0$ is a Lipschitz constant for the Hessian of the function $f$ and $T \geq 1$ is an iteration number.

Our method combines Algorithm 1 with an inexact second-order framework [Xu et al., 2020] in the context of min-max optimization. Indeed, the key difference between Eq. (3.1) and Eq. (4.1) is that the inexact Jacobian $J(\hat{z}_k)$ is used to approximate the exact Jacobian at $\hat{z}_k$ and can be formed and evaluated efficiently in practice. Throughout this section, we impose the following two conditions on the inexact Jacobian construction and the inexact subproblem solving.

Condition 4.1 (Inexact Jacobian regularity) For some $\kappa_J > 0$ and $\tau_k \geq 0$, the inexact Jacobian $J(\hat{z}_k)$ satisfies the following regularity conditions:

$$\|J(\hat{z}_k) - DF(\hat{z}_k)\Delta z_k\| \leq \tau_k \|\Delta z_k\|, \quad \|J(\hat{z}_k)\| \leq \kappa_J,$$

where the iterates $\{\hat{z}_k\}_{k\geq0}$ and the updates $\{\Delta z_k\}_{k\geq0}$ are generated by Algorithm 2.

Condition 4.2 (Sufficient inexact solving) Fixing $\kappa_m \in (0, 1)$, we can solve the nonlinear equation problem in Eq. (4.1) inexact to find $\Delta z_k$ such that

$$\|F(\hat{z}_k) + J(\hat{z}_k) \Delta z_k + 6\rho \|\Delta z_k\| \Delta z_k\| \leq \kappa_m \cdot \min\{\|\Delta z_k\|^2, \|F(\hat{z}_k)\|\},$$

In addition, $\{\hat{z}_k\}_{k\geq0}$ and $\{\Delta z_k\}_{k\geq0}$ are generated by Algorithm 2.

Under Conditions 4.1 and 4.2, our proposed algorithm (cf. Algorithm 2) achieves the same worst-case iteration complexity of $O(\epsilon^{-2}/3)$ for computing an $\epsilon$-global saddle point of the problem in Eq. (1.1) as that of the exact variant (cf. Algorithm 1).

Notably, Condition 4.1 allows for the principled use of many practical techniques to constructing the inexact Jacobian $J(\hat{z}_k)$ in the context of min-max optimization. One such scheme can be described.
for solving the finite-sum min-max optimization problems in the form of

\[
\min_{x \in \mathbb{R}^m} \max_{y \in \mathbb{R}^n} f(x, y) \triangleq \frac{1}{N} \sum_{i=1}^{N} f_i(x, y),
\]

(4.2)

and its special instantiation

\[
\min_{x \in \mathbb{R}^m} \max_{y \in \mathbb{R}^n} f(x, y) \triangleq \frac{1}{N} \sum_{i=1}^{N} f_i(a_i^\top x, b_i^\top y),
\]

(4.3)

where \( N \gg 1 \), each of \( f_i \) is a convex-concave function with bounded and \( \rho \)-Lipschitz Hessian, and \( \{(a_i, b_i)\}_{i=1}^{N} \subseteq \mathbb{R}^m \times \mathbb{R}^n \) are a collection of data samples.

This type of problem is common in the context of optimization and machine learning [Shalev-Shwartz and Ben-David, 2014, Roosta-Khorasani et al., 2014, Roosta-Khorasani and Mahoney, 2019]. Thanks to its finite-sum structure, both uniform and nonuniform subsampling schemes satisfy Condition 4.1 with high probability; indeed, we have the stronger theoretical guarantee \( \|J(\hat{z}_k) - DF(\hat{z}_k)\| \leq \tau_k \), which implies one of two inequalities in Condition 4.1. As a consequence of Theorem 4.1, our subsampled Newton method achieves the order-optimal iteration complexity of \( \Theta(\epsilon^{-2/3}) \) for solving the finite-sum convex-concave min-max optimization problems; see Theorem 4.13 for the details.

### 4.2 Convergence analysis

We provide our results on the iteration complexity of Algorithm 2 in the following theorem.

**Theorem 4.1** Suppose that Assumption 2.4 and 2.5 hold and

\[
0 \leq \tau_k \leq \min\{\tau_0, \frac{\rho(1-\kappa_m)}{4(\kappa_J + 6\rho)} \|F(\hat{z}_k)\| \}, \text{ for all } k \geq 0.
\]

Then, the iterates generated by Algorithm 2 are bounded and, in addition,

\[
gap(\bar{z}_T, \beta) \leq 2112 \sqrt{\frac{\tau_0 - 3\|z^*\|^2}{T}},
\]

where \( z^* = (x^*, y^*) \) is a global saddle point, \( \rho > 0 \) is defined in Assumption 2.5, and \( \beta = 7\|z_0 - z^*\| \).

As such, Algorithm 2 achieves an \( \epsilon \)-global saddle point solution within \( O(\epsilon^{-2/3}) \) iterations.

**Remark 4.2** Theorem 4.1 shows that Algorithm 2 achieves the same iteration complexity as Algorithm 1 and is thus order-optimal regardless of inexact second-order information and inexact subproblem solving under Conditions 4.1 and 4.2.

In the subsequent analysis, we use the same Lyapunov function: \( E_t = \frac{1}{2}\|z_t - z_0\|^2 \). The first lemma gives a descent inequality which is analogous to that in Lemma 3.3.

**Lemma 4.3** Suppose that Assumption 2.4 and 2.5 hold and

\[
0 < \tau_k \leq \min\{\tau_0, \frac{\rho(1-\kappa_m)}{4(\kappa_J + 6\rho)} \|F(\hat{z}_k)\| \}, \text{ for all } k \geq 0.
\]

Then, we have

\[
\sum_{k=1}^{t} \lambda_k (z_k - z)^\top F(z_k) \leq E_0 - E_t + (z_0 - \hat{z}_t)^\top (z_0 - z) - \frac{1}{2T} \left( \sum_{k=1}^{t} \|z_k - \hat{z}_{k-1}\|^2 \right).
\]
Proof. By using the same argument as used in Lemma 3.3, we have

\[ \sum_{k=1}^{t} \lambda_k (z_k - z)^T F(z_k) \leq \mathcal{E}_0 - \mathcal{E}_t + (\hat{z}_0 - z_t)^T (z_0 - z) + \sum_{k=1}^{t} \lambda_k (z_k - \hat{z}_k)^T F(z_k) - \frac{1}{2} \| \hat{z}_k - \hat{z}_{k-1} \|^2. \quad (4.4) \]

In what follows, we bound \( \sum_{k=1}^{t} \lambda_k (z_k - \hat{z}_k)^T F(z_k) - \frac{1}{2} \| \hat{z}_k - \hat{z}_{k-1} \|^2 \). In Algorithm 2, we compute \( \Delta z_k \) such that it is an inexact solution of the nonlinear equation problem given by Eq. (4.1) under Conditions 4.1 and 4.2. Note that we have

\[ \| F(\hat{z}_k) + J(\hat{z}_k) \Delta z_k + 6\rho \| \Delta z_k \| \Delta z_k \| \leq \kappa_m \cdot \min \{ \| \Delta z_k \|^2, \| F(\hat{z}_k) \| \}. \quad (4.5) \]

Using \( z_k = \hat{z}_{k-1} + \Delta z_{k-1} \) and Lemma 2.8, we have

\[ \| F(z_k) - F(\hat{z}_{k-1}) - DF(\hat{z}_{k-1}) \Delta z_{k-1} \| \leq \frac{\rho}{2} \| \Delta z_{k-1} \|^2. \quad (4.6) \]

It suffices to decompose \( (z_k - \hat{z}_k)^T F(z_k) \) and bound this term using Condition 4.1, Eq. (4.5) and (4.6). Indeed, we have

\[ \begin{align*}
(z_k - \hat{z}_k)^T F(z_k) &\leq \| z_k - \hat{z}_k \| \| F(z_k) - F(\hat{z}_{k-1}) - DF(\hat{z}_{k-1}) \Delta z_{k-1} \|
+ \| z_k - \hat{z}_k \| \| J(\hat{z}_{k-1}) \Delta z_{k-1} + 6\rho \| \Delta z_{k-1} \| \Delta z_{k-1} \|
+ \| z_k - \hat{z}_k \| \| (DF(\hat{z}_{k-1}) - J(\hat{z}_{k-1})) \Delta z_{k-1} \| - 6\rho \| \Delta z_{k-1} \| \| \hat{z}_{k-1} - \hat{z}_k \|.
\end{align*} \]

The first and second terms are bounded using Eq. (4.5) and (4.6). For the third term, we derive from Condition 4.1 that \( \| (DF(\hat{z}_{k-1}) - J(\hat{z}_{k-1})) \Delta z_{k-1} \| \leq \tau_{k-1} \| \Delta z_{k-1} \| \). The fourth term is then bounded using the same argument from the proof of Lemma 3.3. Putting these pieces together yields that

\[ \begin{align*}
(z_k - \hat{z}_k)^T F(z_k) &\leq \| z_k - \hat{z}_k \| ((\frac{\rho}{2} + \kappa_m) \| \Delta z_{k-1} \|^2 + \tau_{k-1} \| \Delta z_{k-1} \|) \\
&\quad - 6\rho \| \Delta z_{k-1} \|^3 + 6\rho \| \Delta z_{k-1} \|^2 \| \hat{z}_{k-1} - \hat{z}_k \|.
\end{align*} \quad (4.7) \]

We claim that

\[ (\frac{\rho}{2} + \kappa_m) \| \Delta z_{k-1} \|^2 + \tau_{k-1} \| \Delta z_{k-1} \| \leq \rho \| \Delta z_{k-1} \|^2. \quad (4.8) \]

Indeed, for the case of \( \| \Delta z_{k-1} \| \geq 1 \), we have

\[ (\frac{\rho}{2} + \kappa_m) \| \Delta z_{k-1} \|^2 + \tau_{k-1} \| \Delta z_{k-1} \| \leq \left( \frac{\rho}{2} + \kappa_m + \tau_{k-1} \right) \| \Delta z_{k-1} \|^2. \]

which together with the fact that \( 0 < \kappa_m < \min \{1, \frac{\rho}{2} \} \) and \( \tau_{k-1} \leq \tau_0 < \frac{\rho}{4} \) can yield Eq. (4.8). Otherwise, we have \( \| \Delta z_{k-1} \| < 1 \) and obtain from Conditions 4.1 and 4.2 that

\[ \kappa_m \| F(\hat{z}_{k-1}) \| \geq \| F(\hat{z}_{k-1}) + J(\hat{z}_{k-1}) \Delta z_{k-1} + 6\rho \| \Delta z_{k-1} \| \| \Delta z_{k-1} \|
\geq \| F(\hat{z}_{k-1}) \| - \kappa_J \| \Delta z_{k-1} \|^2 - 6\rho \| \Delta z_{k-1} \|^2
\geq \| F(\hat{z}_{k-1}) \| - (\kappa_J + 6\rho) \| \Delta z_{k-1} \|.
\]

Rearranging the above inequality and using \( 0 \leq \tau_{k-1} \leq \frac{\rho(1-\kappa_m)}{4(\kappa_J + 6\rho)} \| F(\hat{z}_{k-1}) \| \) yields

\[ \| \Delta z_{k-1} \| \geq \frac{1-\kappa_m}{\kappa_J + 6\rho} \| F(\hat{z}_{k-1}) \| \geq \frac{4\tau_{k-1}}{\rho}. \]
Since $0 < \kappa_m < \min\{1, \frac{\rho}{\sqrt{2}}\}$ again, we get Eq. (4.8) as follows,

\[
\left(\frac{\rho}{2} + \kappa_m\right)\|\Delta z_{k-1}\|^2 + \tau_{k-1}\|\Delta z_{k-1}\| \leq \left(\frac{\rho}{2} + \kappa_m + \frac{\tau_{k-1}}{\|\Delta z_{k-1}\|}\right)\|\Delta z_{k-1}\|^2 \leq \rho\|\Delta z_{k-1}\|^2.
\]

Plugging Eq. (4.8) into Eq. (4.7) and using $\|z_k - \hat{z}_k\| \leq \|\Delta z_{k-1}\| + \|\hat{z}_{k-1} - \hat{z}_k\|$ yields

\[
(z_k - \hat{z}_k)^T F(z_k) \leq 7\rho\|\Delta z_{k-1}\|^2\|\hat{z}_{k-1} - \hat{z}_k\| - 5\rho\|\Delta z_{k-1}\|^3.
\]

Since $\frac{1}{30} \leq \lambda_k \rho\|\Delta z_{k-1}\| \leq \frac{1}{14}$ for all $k \geq 1$, we have

\[
\sum_{k=1}^{t} \lambda_k (z_k - \hat{z}_k)^T F(z_k) - \frac{1}{7}\|\hat{z}_k - \hat{z}_{k-1}\|^2 \\
\leq \sum_{k=1}^{t} \left(7\lambda_k \rho\|\Delta z_{k-1}\|\|\hat{z}_{k-1} - \hat{z}_k\| - \frac{1}{7}\|\hat{z}_{k-1} - \hat{z}_k\|^2 - 5\lambda_k \rho\|\Delta z_{k-1}\|^3\right) \\
\leq \sum_{k=1}^{t} \left(\frac{1}{7}\|\Delta z_{k-1}\|\|\hat{z}_{k-1} - \hat{z}_k\| - \frac{1}{7}\|\hat{z}_{k-1} - \hat{z}_k\|^2 - \frac{1}{7}\|\Delta z_{k-1}\|^2\right) \\
\leq \sum_{k=1}^{t} \max_{\eta \geq 0} \left\{\frac{1}{7}\|\Delta z_{k-1}\|\eta - \frac{1}{7}\eta^2\} - \frac{1}{6}\|\Delta z_{k-1}\|^2\right\} = -\frac{1}{21} \left(\sum_{k=1}^{t} \|\Delta z_{k-1}\|^2\right).
\]

Therefore, we conclude from Eq. (4.4), $\hat{z}_0 = z_0$ and $\Delta z_{k-1} = z_k - \hat{z}_{k-1}$ that

\[
\sum_{k=1}^{t} \lambda_k (z_k - z)^T F(z_k) \leq \mathcal{E}_0 - \mathcal{E}_t + (z_0 - \hat{z}_t)^T (z_0 - z) - \frac{1}{21} \left(\sum_{k=1}^{t} \|z_k - \hat{z}_{k-1}\|^2\right).
\]

This completes the proof. \qed

**Proof of Theorem 4.1.** Since the descent inequalities in Lemmas 3.3 and 4.3 are the same, Lemma 3.4 and 3.5 also hold true for Algorithm 2. As such, we can apply the same argument used for proving Theorem 3.1 and have

\[
\|\hat{z}_k - z^*\| \leq 3\|z_0 - z^*\| \leq \beta, \quad \|z_k - z^*\| \leq 7\|z_0 - z^*\| = \beta,
\]

and

\[
gap(\hat{z}_T, \beta) \leq \frac{2112\sqrt{3}\rho\|z_0 - z^*\|^3}{T^{3/2}}.
\]

Therefore, we conclude from the above inequality that there exists some $T > 0$ such that the output $\hat{z} = \text{Inexact-Newton-MinMax}(z_0, \rho, T)$ satisfies that $\gap(\hat{z}, \beta) \leq \epsilon$ and the total number of iterations is bounded by $O(\rho^{2/3}\|z_0 - z^*\|^2 \epsilon^{-2/3})$. \qed

### 4.3 Inexact subproblem solving and complexity analysis

We clarify how to obtain an inexact solution of the nonlinear equation problem in Eq. (4.1) such that Condition 4.2 holds. To that end, we present a new subroutine that solves each subproblem using a single Schur decomposition and $O(\log \log (1/\epsilon))$ calls to a linear system solver in a quasi-upper-triangular
Combining the second equation with the expression of $J$ gives

Putting these pieces together yields the desired expressions of $\psi(\hat{z})$ and $\lambda$ for the nonlinear equation problem in Eq. (4.1) as

$$F(\hat{z}) + J(\hat{z})\Delta z + 6\rho\|\Delta z\| \Delta z = 0.$$  

This is then equivalent to finding a pair $(\Delta z, \lambda)$ for which

$$(J(\hat{z}) + \lambda I)\Delta z = -F(\hat{z}), \quad \lambda = 6\rho\|\Delta z\|.$$  

Although $J(\hat{z})$ is not symmetric, it has a Schur decomposition $J(\hat{z}) = QUQ^{-1}$ where $U$ is quasi-upper-triangular (since all entries of $J(\hat{z})$ are real) in the sense that it is a block diagonal matrix with block size at most $2 \times 2$ and $Q$ is a unitary matrix. Then, we have $J(\hat{z}) + \lambda I = Q(U + \lambda I)Q^{-1}$. In the convex-concave setting, $J(\hat{z})$ is positive semidefinite and thus $J(\hat{z}) + \lambda I$ is positive definite.

In this regard, we define

$$\Delta z(\lambda) \equiv -(J(\hat{z}) + \lambda I)^{-1}F(\hat{z}) = -Q(U + \lambda I)^{-1}Q^{-1}F(\hat{z}),$$

and obtain from Eq. (4.9) and the above definition that the solution of $(\Delta z, \lambda)$ we are looking for depends upon the nonlinear equality $\lambda = 6\rho\|\Delta z(\lambda)\|$. For convenience, we define $\psi(\lambda) = \|\Delta z(\lambda)\|^2$ and examine $\psi(\lambda)$ in the following proposition.

**Proposition 4.4** The first-order and second-order derivatives of $\psi$ are given by

$$\psi'(\lambda) = -2\Delta z(\lambda)^\top (J(\hat{z}) + \lambda I)^{-1}\Delta z(\lambda),$$

and

$$\psi''(\lambda) = 2\|\Delta z(\lambda)\|^2 + 4\Delta z(\lambda)^\top (J(\hat{z}) + \lambda I)^{-2}\Delta z(\lambda).$$

If $F(\hat{z}) \neq 0$, the function $\psi(\lambda)$ is strictly decreasing and convex when $\lambda > 0$.

**Proof.** Since $\psi(\lambda) = \|\Delta z(\lambda)\|^2$, we have

$$\psi'(\lambda) = 2\Delta z(\lambda)^\top \nabla_\lambda \Delta z(\lambda), \quad \psi''(\lambda) = 2\|\nabla_\lambda \Delta z(\lambda)\|^2 + 2\Delta z(\lambda)^\top \nabla^2_{\lambda\lambda} \Delta z(\lambda).$$

By differentiating the equation $(J(\hat{z}) + \lambda I)\Delta z(\lambda) = -F(\hat{z})$, we have

$$(J(\hat{z}) + \lambda I)\nabla_\lambda \Delta z(\lambda) + \Delta z(\lambda) = 0, \quad (J(\hat{z}) + \lambda I)^2 \nabla^2_{\lambda\lambda} \Delta z(\lambda) + 2\nabla_\lambda \Delta z(\lambda) = 0,$$

Rearranging the first equation implies that

$$\nabla_\lambda \Delta z(\lambda) = -(J(\hat{z}) + \lambda I)^{-1}\Delta z(\lambda).$$

Combining the second equation with the expression of $\nabla_\lambda \Delta z(\lambda)$ yields

$$\nabla^2_{\lambda\lambda} \Delta z(\lambda) = -2(J(\hat{z}) + \lambda I)^{-2}\Delta z(\lambda).$$

Putting these pieces together yields the desired expressions of $\psi'(\lambda)$ and $\psi''(\lambda)$. Since $F(\hat{z}) \neq 0$ and $J(\hat{z})$ is positive semidefinite, we have $\psi'(\lambda) < 0$ and $\psi''(\lambda) \geq 0$ when $\lambda > 0$. This completes the proof. \qed
The nonlinear equality \( \lambda = 6\rho \| \Delta z(\lambda) \| \) is equivalent to \( \lambda = 6\rho \sqrt{\psi(\lambda)} \) which can be reformulated as the following one-dimensional nonlinear equation problem:

\[
\phi(\lambda) \triangleq \sqrt{\psi(\lambda)} - \frac{\lambda}{6\rho} = 0. \tag{4.11}
\]

In the following proposition, we examine \( \phi(\lambda) \) and prove several key properties.

**Proposition 4.5** Suppose \( F(\hat{z}) \neq 0 \). Then, we have the function \( \phi(\lambda) \) is strictly decreasing and convex when \( \lambda > 0 \). Its first-order derivative is

\[
\phi'(\lambda) = -\frac{\Delta z(\lambda)^T (J(\hat{z}) + \lambda I)^{-1} \Delta z(\lambda)}{\| \Delta z(\lambda) \|} \cdot \frac{1}{6\rho}.
\]

Proof. Using Eq. (4.11), we have

\[
\phi'(\lambda) = \frac{1}{2} \frac{\psi'(\lambda)}{\sqrt{\psi(\lambda)}} - \frac{1}{6\rho}, \quad \phi''(\lambda) = \frac{1}{4} \frac{2\psi''(\lambda) \psi(\lambda) - (\psi'(\lambda))^2}{(\psi(\lambda))^{3/2}}.
\]

By Proposition 4.4, we have

\[
\phi'(\lambda) = -\frac{\Delta z(\lambda)^T (J(\hat{z}) + \lambda I)^{-1} \Delta z(\lambda)}{\| \Delta z(\lambda) \|} - \frac{1}{6\rho} < 0, \quad \text{when } \lambda > 0.
\]

We also have

\[
\phi''(\lambda) = \frac{\| \Delta z(\lambda) \|^2 \| (J(\hat{z}) + \lambda I)^{-1} \Delta z(\lambda) \|^2 + 2\| \Delta z(\lambda)^T (J(\hat{z}) + \lambda I)^{-1} \Delta z(\lambda) - (\Delta z(\lambda)^T (J(\hat{z}) + \lambda I)^{-1} \Delta z(\lambda))^2 \| \Delta z(\lambda) \|^2}{\| \Delta z(\lambda) \|^3} \geq 0, \quad \text{when } \lambda > 0,
\]

where the first inequality holds true since \( J(\hat{z}) \) is positive semidefinite, \( F(\hat{z}) \neq 0 \) and \( \lambda > 0 \), and the second inequality holds true because of the the Cauchy-Schwarz inequality. This completes the proof.

The required solution is the unique positive root to Eq. (4.11) since \( \phi(\lambda) \) is decreasing. Let \( \lambda^0 > 0 \) be given with \( \phi(\lambda^0) > 0 \), we first perform one Schur decomposition of \( J(\hat{z}) \):

\[
J(\hat{z}) = QUQ^{-1}.
\]

A typical iteration of the unit-stepsize Newton method for finding such root replaces the current iterate \( \lambda^j > 0 \) with the improved estimate \( \lambda^{j+1} \) for which

\[
\lambda^{j+1} = \lambda^j - \frac{\phi(\lambda^j)}{\phi'(\lambda^j)}. \tag{4.12}
\]

The value of \( \phi(\lambda^j) \) can be obtained by solving \( \Delta z(\lambda^j) = -Q(U + \lambda^j I)^{-1}Q^{-1}F(\hat{z}) \), and that of \( \phi'(\lambda^j) \) can be obtained using Proposition 4.5 once \( \Delta z(\lambda^j) \) is available (solving a linear system is required). This implies that \( \phi(\lambda^j) \) and \( \phi'(\lambda^j) \) can be computed by two calls to a linear system solver in a quasi-upper-triangle system.

In terms of complexity, the cost of a single Schur decomposition is \( O((m + n)\omega) \) where \( \omega \approx 2.3728 \) is the matrix multiplication constant and the cost of one Newton iteration is \( O((m + n)^2) \). In terms of convergence, the unit-stepsize Newton method by itself is not a reliable method and the iterates do not converge in general. However, the convexity of \( \phi \) established in Proposition 4.5 has useful properties.
Theorem 4.6 Suppose that the iterates \( \{\lambda^j\}_{j \geq 0} \) are generated by a unit-stepsize Newton method with \( \lambda^0 > 0 \) with \( \phi(\lambda^0) \geq 0 \). Then, we have \( \lambda^j > 0 \) and \( \phi(\lambda^j) \geq 0 \). As a consequence, the iterates converge monotonically towards the unique solution \( \lambda^* \). The convergence rate is globally \( Q \)-linear with a factor at least \( 1 - \phi'(\lambda^*)/\phi'(\lambda^0) \) and is ultimately \( Q \)-quadratic.

Proof. Proposition 4.5 guarantees that \( \phi'(\lambda^0) < 0 \) when \( \lambda > 0 \), and it follows from Eq. (4.12) that \( \lambda^1 > \lambda^0 > 0 \). Proposition 4.5 also guarantees the convexity and differentiability of \( \phi \) which together with Eq. (4.12) implies that

\[
\phi(\lambda^1) \geq \phi(\lambda^0) + (\lambda^1 - \lambda^0)\phi'(\lambda^0) = 0.
\]

Repeating this argument yields that \( \lambda^j > 0 \) and \( \phi(\lambda^j) \geq 0 \). In addition, \( \phi \) is strictly decreasing. Thus, the iterates converge monotonically towards the unique solution.

Suppose that \( \lambda^* \) is the unique solution. Then, the mean value theorem implies

\[
\phi(\lambda^j) = \phi(\lambda^*) + (\lambda^j - \lambda^*)\phi'(\tilde{\lambda}) = (\lambda^j - \lambda^*)\phi'(\tilde{\lambda}), \quad \text{for some } \tilde{\lambda} \in (\lambda^j, \lambda^*).
\]

Combining this with Eq. (4.12) yields

\[
|\lambda^* - \lambda^{j+1}| = |\lambda^* - \lambda^j| \left(1 - \frac{\phi'(\tilde{\lambda})}{\phi'(\lambda^j)} \right) \leq |\lambda^* - \lambda^j| \cdot \left|1 - \frac{\phi'(\lambda^j)}{\phi'(\lambda^0)} \right|.
\]

Proposition 4.5 guarantees that \( \phi'(\lambda) \) is increasing and strictly less than 0. Thus, we have \( \phi'(\lambda^0) \leq \phi'(\lambda^j) \leq \phi'(\lambda^*) < 0 \) which implies that

\[
0 \leq 1 - \frac{\phi'(\lambda^j)}{\phi'(\lambda^0)} \leq 1 - \frac{\phi'(\lambda^*)}{\phi'(\lambda^0)} < 1.
\]

Putting everything together implies that the convergence rate is globally \( Q \)-linear with a factor at least \( 1 - \phi'(\lambda^*)/\phi'(\lambda^0) \). The asymptotic \( Q \)-quadratic convergence of the Newton iteration follows because the Jacobian of \( \phi \) is nonsingular at the unique solution \( \lambda^* \) (i.e., \( \phi'(\lambda^*) \neq 0 \)). This completes the proof. \( \square \)

Remark 4.7 Our approach is inspired by Adil et al. [2022], who reformulated the subproblem in their algorithm as the nonlinear equality \( \lambda = 6\rho \|\Delta z(\lambda)\| \) and proposed a bisection method as a subroutine. In total, this requires a single Schur decomposition and \( O(\log(1/\epsilon)) \) calls to a linear system solver for a quasi-upper-triangular system. Our key finding is that the Newton method is better than the bisection method for solving the nonlinear equation \( \lambda = 6\rho \|\Delta z(\lambda)\| \). Indeed, the simple reformulation in Eq. (4.11) and the unit-stepsize implementation achieve global linear and local quadratic convergence guarantees. Thus, by comparison, the proposed subroutine only requires a single Schur decomposition and \( O(\log \log(1/\epsilon)) \) calls to a linear system solver for a quasi-upper-triangular system.

Remark 4.8 We note also that Huang et al. [2022] reformulated the subproblem in their algorithm as the two-dimensional nonlinear equation problem (see Huang et al. [2022, Eq.(16)]) and proposed the Newton method as a subroutine. However, no theoretical guarantee was provided, even in a local sense; indeed, the proposed nonlinear equation is complex and it is not clear if it satisfies essential properties (e.g., the nonsingularity of Jacobian). Our approach is similar in spirit to Conn et al. [2000]; they consider the choice of \( \phi \triangleq 1/\sqrt{\psi(\lambda)} - 6\rho/\lambda \) and prove that it is concave in optimization setting where the second-order information is a symmetric matrix. Their analysis is unfortunately not valid here since \( J(\tilde{z}) \) is, in general, not symmetric.
4.4 Finite-sum min-max optimization

We give concrete examples to clarify the ways to construct the inexact Jacobian such that Condition 4.1 holds true. The key ingredient is random sampling which can significantly reduce the computational cost in an optimization setting [Xu et al., 2020] and we show that such technique can be employed for solving finite-sum min-max optimization problems in Eq. (4.2) and (4.3).

We let the probability distribution of sampling $\xi \in \{1, 2, \ldots, N\}$ be defined as $\text{Prob}(\xi = i) = p_i \geq 0$ for $i = 1, 2, \ldots, N$ and $S \subseteq \{1, 2, \ldots, N\}$ denote a collection of sampled indices ($|S|$ is its cardinality). Then, we can construct the inexact Jacobian as follows,

$$J(z) = \frac{1}{N|S|} \sum_{i \in S} \frac{1}{p_i} DF_i(z), \quad \text{for } DF_i(z) = \begin{bmatrix} \nabla^2_{xx} f_i(x, y) & \nabla^2_{xy} f_i(x, y) \\ -\nabla^2_{xy} f_i(x, y) & -\nabla^2_{yy} f_i(x, y) \end{bmatrix}. \quad (4.13)$$

This construction is referred to as the subsampled Jacobian and can offer significant computational savings if $|S| \ll N$ in big-data regime when $N \gg 1$.

In the general finite-sum setting with Eq. (4.2), we suppose

$$\sup_{z} \|DF_i(z)\| \leq B_i, \quad \text{for all } i \in \{1, 2, \ldots, N\}, \quad (4.14)$$

and let $B_{\text{max}} = \max_{1 \leq i \leq N} B_i$. For the uniform sampling (i.e., $p_i = \frac{1}{N}$), we summarize the sample complexity results in the following lemma. The proof is omitted for brevity.

**Lemma 4.9** Suppose that Eq. (4.14) holds true and let $B_{\text{max}}$ and $0 < \tau, \delta < 1$ be defined properly. A uniform sampling with or without replacement is performed to form the subsampled Jacobian; indeed, $J(z)$ is constructed using Eq. (4.13) with $p_i = \frac{1}{N}$ and the sample size satisfies

$$|S| \geq \Theta^U(\tau, \delta) := \frac{16B_{\text{max}}}{\tau^2} \log \left( \frac{2(m+n)}{\delta} \right).$$

Then, we have

$$\text{Prob}(\|J(z) - DF(z)\| \leq \tau) \geq 1 - \delta.$$ 

**Remark 4.10** *Lemma 4.9* shows that the inexact Jacobian satisfies Condition 4.1 with probability $1 - \delta$ under certain $\tau$ and $\kappa_J = B_{\text{max}}$ if it is constructed using the uniform sampling and the size $|S| = \Omega \left( \frac{B_{\text{max}}^2}{\tau^2} \log \left( \frac{m+n}{\delta} \right) \right)$. Indeed, the first inequality holds true with probability $1 - \delta$ since $\text{Prob}(\|J(z) - DF(z)\| \leq \tau) \geq 1 - \delta$, and the second inequality holds true since $\kappa_H = B_{\text{max}}$ (this is a deterministic statement).

In the special finite-sum setting with Eq. (4.3), we can construct a more “informative” distribution of sampling $\xi \in \{1, 2, \ldots, N\}$ as opposed to simplest uniform sampling. It is advantageous to bias the probability distribution towards carefully picking indices corresponding to those relevant $f_i$’s in forming the Jacobian. However, constructing inexact Hessian and corresponding sample complexity guarantee from Xu et al. [2020, Section 3.1] requires $\nabla^2 f_i$ to be rank-one, which is not valid here. To address this issue, we avail ourselves of the operator-Bernstein inequality [Gross and Nesme, 2010].

The Jacobian of $F$ can be rewritten as $DF(z) = \frac{1}{N} \sum_{i=1}^{N} \Lambda_i DF_i(a_i^\top x, b_i^\top y) \Lambda_i^\top$ where $\Lambda_i = \begin{bmatrix} a_i & b_i \end{bmatrix} \in \mathbb{R}^{(m+n)\times 2}$ and $DF_i(x, y) \in \mathbb{R}^{2\times 2}$. Then, the resulting compact form is $DF(z) = \Lambda^\top \Sigma \Lambda$ where

$$\Lambda^\top = \begin{bmatrix} | & \cdots & | \\ \Lambda_1 & \cdots & \Lambda_N \end{bmatrix} \quad \text{and} \quad \Sigma = \frac{1}{N} \begin{bmatrix} DF_1(a_1^\top x, b_1^\top y) & \cdots & \cdots \\ \vdots & \ddots & \vdots \\ \cdots & \cdots & DF_N(a_N^\top x, b_N^\top y) \end{bmatrix}. \quad (4.15)$$

20
We suppose
\[ \sup_{(x,y)} \|DF_i(a_i^\top x, b_i^\top y)\|((\|a_i\|^2 + \|b_i\|^2) \leq B_i, \text{ for all } i \in \{1, 2, \ldots, N\}, \tag{4.16} \]
and let \( B_{\text{avg}} = \frac{1}{N} \sum_{i=1}^{N} B_i \). For the uniform sampling with the particular nonuniform distribution given by
\[ p_i = \frac{\|DF_i(a_i^\top x, b_i^\top y)\|((\|a_i\|^2 + \|b_i\|^2)}{\sum_{i=1}^{N} \|DF_i(a_i^\top x, b_i^\top y)\|((\|a_i\|^2 + \|b_i\|^2)}, \tag{4.17} \]
The following lemma summarizes the results on the sample complexity.

**Lemma 4.11** Suppose that Eq. (4.16) holds true and let \( B_{\text{avg}} \) and \( 0 < \tau, \delta < 1 \) be defined properly. A nonuniform sampling is performed to form the subsampled Jacobian; indeed, \( J(z) \) is constructed using Eq. (4.13) with \( p_i > 0 \) in Eq. (4.17) and the sample size satisfies
\[ |S| \geq \Theta^N(\tau, \delta) := \frac{4B_{\text{avg}}^2}{\tau^2} \log \left( \frac{2(m+n)}{\delta} \right). \]
Then, we have
\[ \text{Prob}(\|J(z) - DF(z)\| \leq \tau) \geq 1 - \delta. \]

**Proof.** Fixing \( z \in \mathbb{R}^{m+n} \), we obtain from Eq. (4.13) and (4.15) that \( J(z) = \frac{1}{|S|} \sum_{j=1}^{|S|} J_j \) where each random matrix \( J_j \) is random and satisfies that \( \text{Prob}(J_j = \frac{1}{p_i} \Lambda_i \Sigma_i \Lambda_i^\top) = p_i \) with \( p_i > 0 \) in Eq. (4.17). For simplicity, we define
\[ X_j = J_j - DF(z) = J_j - \Lambda^\top \Sigma \Lambda, \quad X = \sum_{j=1}^{|S|} X_j = |S|(J(z) - \Lambda^\top \Sigma \Lambda). \]
It is easy to verify that \( \mathbb{E}[X_j] = 0 \) and
\[ \|\mathbb{E}[X_j^2]\| \leq \left( \frac{1}{N} \sum_{i=1}^{N} \|DF_i(a_i^\top x, b_i^\top y)\|((\|a_i\|^2 + \|b_i\|^2) \right)^2 \text{ Eq. (4.16)} \leq B_{\text{avg}}^2. \]
Applying the operator-Bernstein inequality yields
\[ \text{Prob}(\|J(z) - DF(z)\| \geq \tau) = \text{Prob}(\|X\| \geq \tau|S|) \leq 2(m+n) \exp \left( \frac{\tau^2|S|}{4B_{\text{avg}}^2} \right) \leq \delta. \]
This completes the proof. \( \square \)

**Remark 4.12** Compared to Lemma 4.9, the computation of sampling probability in Lemma 4.11 requires going through the whole dataset and the cost is \( O((m+n)N) \). Nonetheless, the computational savings with smaller sample size dominates such extra cost of computing the sampling probability in optimization setting [Xu et al., 2016]. In particular, the sample size from Lemma 4.11 is smaller as \( B_{\text{avg}} \ll B_{\text{max}} \) which occurs if one \( B_i \) is much larger than the others. In addition, the sample size is proportional to the log of the failure probability in Lemma 4.9 and 4.11, allowing the use of a very small failure probability without increasing the sample size significantly.

Combining Algorithm 2 and these random sampling strategies gives the first class of subsampled Newton methods for solving finite-sum min-max optimization problems. We provide the scheme in Algorithm 3 and present the iteration complexity and total complexity guarantees in the high-probability sense.
Algorithm 3 Subsampled-Newton-MinMax($z_0$, $\rho$, $T$, $\delta$)

Input: initial point $z_0$, Lipschitz parameter $\rho$, iteration number $T \geq 1$ and failure probability $\delta \in (0, 1)$.
Initialization: set $\hat{z}_0 = z_0$ as well as $0 < \kappa_m < \min\{1, \frac{4}{T}\}$ and $0 < \tau_0 < \frac{4}{T}$.

for $k = 0, 1, 2, \ldots, T - 1$ do

STEP 1: If $z_k$ is a global saddle point of the problem in Eq. (4.2) or (4.3), then stop.

STEP 2: Construct the inexact Jacobian $J(\hat{z}_k)$ using Eq. (4.13) with the sample set of $|S| \geq \Theta^U(\tau_k, 1 - \frac{1}{\sqrt{T-\delta}})$ (uniform) or $|S| \geq \Theta^N(\tau_k, 1 - \frac{1}{\sqrt{T-\delta}})$ (non-uniform) given $0 < \tau_k \leq \min\{\tau_0, \frac{\rho(1-\kappa_m)}{4(B_{\max}+6\rho)}\|F(\hat{z}_k)\|\}$.

STEP 3: Compute an inexact solution $\Delta z_k$ of the following subproblem

$$F(\hat{z}_k) + J(\hat{z}_k)\Delta z_k + 6\rho\|\Delta z_k\|\Delta z_k = 0.$$ 

such that Condition 4.2 hold true.

STEP 4: Compute $\lambda_{k+1} > 0$ such that $\frac{1}{3m} \leq \lambda_{k+1}\rho\|\Delta z_k\| \leq \frac{1}{11}$.

STEP 5: Compute $z_{k+1} = \hat{z}_k + \Delta z_k$.

STEP 6: Compute $z_{k+1} = \hat{z}_k + \Delta z_k$.
end for

Output: $z_T = \frac{1}{\sum_{k=1}^{T} \lambda_k} \left(\sum_{k=1}^{T} \lambda_k z_k\right)$.

Theorem 4.13 Suppose that Assumption 2.4 and 2.5 hold. Then, the iterates generated by Algorithm 3 are bounded and Algorithm 3 achieves an $\epsilon$-global saddle point solution within $O(\epsilon^{-2/3})$ iterations with the probability at least $1 - \delta$. The total complexity bound of inexact methods is $O((m+n)^{\omega} \epsilon^{-2/3} + (m+n)^2 \epsilon^{-2/3} \log \log(1/\epsilon))$ where $\omega \approx 2.3728$ is the matrix multiplication constant.

Proof of Theorem 4.13 Since Algorithm 3 is a combination of Algorithm 2 and the random sampling strategy in Eq. (4.13) with $0 < \tau_k \leq \min\{\tau_0, \frac{\rho(1-\kappa_m)}{4(B_{\max}+6\rho)}\|F(\hat{z}_k)\|\}$ and $\kappa_H = B_{\max}$, we can obtain the desired results from Theorems 4.1 and 4.6 if the following statement holds true:

$$\text{Prob}(\|J(\hat{z}_k) - DF(\hat{z}_k)\| \leq \tau_k \text{ for all } 0 \leq k \leq T - 1) \geq 1 - \delta.$$ \hspace{1cm} (4.18)

To guarantee an overall accumulative success probability of $1 - \delta$ across all $T$ iterations, it suffices to set the per-iteration failure probability as $1 - \frac{1}{\sqrt{T - \delta}}$ as we have done in Algorithm 3. Moreover, we have $1 - \frac{1}{\sqrt{T - \delta}} = O(\frac{\delta}{T}) = O(\delta \epsilon^{2/3})$. Since this failure probability has only been proven to appear in the logarithmic factor for the sample size in both Lemma 4.9 and 4.11, the extra cost will not be dominating. As such, when Algorithm 3 terminates, all of the Jacobian approximations have satisfied Eq. (4.18). This completes the proof. \hfill \Box

5 Numerical Experiments

We evaluate the performance of our methods for min-max optimization problems with synthetic and real data. The baseline methods include extragradient and optimistic gradient descent ascent method (we refer to them as EG1 and OGDA1), stochastic variants of EG and OGDA (which we refer to as SEG and SOGDA) and second-order variants of EG and OGDA (which we refer to as EG2 and OGDA2).

| Name   | Description    | $N$  | $n$  | Scaled Interval |
|--------|----------------|------|------|-----------------|
| a9a    | UCI adult      | 32561| 123  | [0, 1]          |
| covetypetype | forest covetypetype | 581012 | 54   | [0, 1]          |
| w8a    | -              | 49749| 300  | [0, 1]          |

We exclude the methods in Huang et al. [2022] since their guarantees are proved under additional error bound conditions. All methods were implemented using MATLAB R2023b on a MacBook Pro with an Intel Core i9 2.4GHz and 16GB memory.

5.1 Cubic regularized bilinear min-max problem

Following the setup of Jiang and Mokhtari [2022], we consider the problem in the following form:

$$
\min_{x \in \mathbb{R}^n} \max_{y \in \mathbb{R}^n} f(x, y) = \frac{\rho}{6} \|x\|^3 + y^\top (Ax - b),
$$

(5.1)

where $\rho > 0$, the entries of $b \in \mathbb{R}^n$ are generated independently from $[-1, 1]$ and $A \in \mathbb{R}^{n \times n}$ is given by

$$
A = \begin{bmatrix}
1 & -1 & -1 & \cdots & \cdots & -1 \\
1 & \cdots & \cdots & 1 & -1 & 1
\end{bmatrix}.
$$

This min-max optimization problem is convex-concave and the function $f$ is $\rho$-Hessian Lipschitz. It has a unique global saddle point $x^* = A^{-1}b$ and $y^* = -\frac{\rho}{2} \|x^*\|(A^\top)^{-1}x^*$. We use the restricted gap function defined in Section 2 as the evaluation metric. In our experiment, the parameters are chosen as $\rho = \frac{1}{20n}$ and $n \in \{50, 100, 200\}$. Since the exact second-order information is available here, we use Algorithm 2 with $\tau_0 = 0$ (the exact Hessian) and compute each subproblem up to a very high accuracy with $\kappa_m = 10^{-8}$ using our subroutine. The baseline methods include EG1, OGD1, EG2 and OGDA2 where all of these methods require the exact second-order information. We implement EG2 using the pseudocode of Bullins and Lai [2022, Algorithm 5.2 and 5.3] with the fine-tuning parameters. The implementation of OGDA2 is based on the code provided by the author of Jiang and Mokhtari [2022] with the line search parameter $(\alpha, \beta) = (0.5, 0.8)$.

Figure 1 highlights that the second-order methods can be far superior to the first-order methods in terms of solution accuracy: the first-order methods barely make any progress when the second-order methods converge successfully. Moreover, our method outperforms other second-order methods [Bullins and Lai, 2022, Jiang and Mokhtari, 2022] in terms of both iteration numbers and computational time thanks to its simple scheme without line search. Nonetheless, we remark that this does not eliminate the advantages of using line search in min-max optimization. Indeed, we find that the line search scheme from Jiang and Mokhtari [2022] is very powerful in practice and their methods with aggressive choices of $(\alpha, \beta)$ outperforms our method in many cases. However, such choices make their method unstable. Thus, we choose $(\alpha, \beta) = (0.5, 0.8)$ which is conservative yet more robust. We believe it is promising to study the line search scheme from Jiang and Mokhtari [2022] and see if modifications can speed up second-order min-max optimization in a universal manner.
Our Method for AUC maximization (see Table 5.2).

Figure 1: Performance of all the algorithms for $n \in \{50, 100, 200\}$ when $\rho = \frac{1}{20m}$ is set. The numerical results are presented in terms of iteration count (Top) and computational time (Bottom).

5.2 AUC maximization problem

The problem of maximizing an area under the receiver operating characteristic curve is a paradigm that learns a classifier for imbalanced data [Yang and Ying, 2022]. The goal is to find a classifier $\theta \in \mathbb{R}^n$ that maximizes the AUC score on a set of samples $\{(a_i, b_i)\}_{i=1}^N$, where $a_i \in \mathbb{R}^n$ and $b_i \in \{-1, +1\}$.

We consider the min-max formulation for AUC maximization [Ying et al., 2016, Shen et al., 2018]:

$$
\min_{x=(\theta, a, v)} \max_y \frac{1}{N} \left\{ \sum_{i=1}^N (\theta^T a_i - u)^2 \mathbb{I}_{[b_i=1]} \right\} + \frac{\rho}{N} \left\{ \sum_{i=1}^N (\theta^T a_i - v)^2 \mathbb{I}_{[b_i=-1]} \right\} + 2(1+y) \left( \sum_{i=1}^N \theta^T a_i (\hat{p} \mathbb{I}_{[b_i=-1]} - (1-\hat{p}) \mathbb{I}_{[b_i=1]}) \right) + \frac{\rho}{6} \|x\|^3 - \hat{p}(1-\hat{p})y^2,
$$

where $\lambda > 0$ is a scalar, $\mathbb{I}_{[\cdot]}$ is an indicator function and $\hat{p} = \frac{\#\{i: b_i=1\}}{N}$ be the proportion of samples with positive label. It is clear that the min-max optimization problem in Eq. (5.2) is convex-concave and has the finite-sum structure in the form of Eq. (4.2) with the function $f_i(x, y)$ given by

$$
f_i(x, y) = (1 - \hat{p})(\theta^T a_i - u)^2 \mathbb{I}_{[b_i=1]} + \hat{p}(\theta^T a_i - v)^2 \mathbb{I}_{[b_i=-1]} + 2(1+y)\theta^T a_i (\hat{p} \mathbb{I}_{[b_i=-1]} - (1-\hat{p}) \mathbb{I}_{[b_i=1]}) + \frac{\rho}{6} \|x\|^3 - \hat{p}(1-\hat{p})y^2.
$$

The above function is in the cubic form and the min-max problem has a global saddle point. We use the restricted gap function as the evaluation metric. In our experiment, the parameter is chosen empirically as $\rho = \frac{1}{N}$ and we use three LIBSVM datasets\footnote{https://www.csie.ntu.edu.tw/~cjlin/libsvm/} for AUC maximization (see Table 1). Since this min-max...
problem has a finite-sum structure, we can apply Algorithm 3 with uniform sampling. The baseline methods include Algorithm 2 as well as SEG and SOGDA [Juditsky et al., 2011, Hsieh et al., 2019, Mertikopoulos et al., 2019, Kotsalis et al., 2022]. We choose the stepsizes for SEG and SOGDA in the form of $\frac{c}{\sqrt{k+1}}$ where $c > 0$ is tuned using grid search and $k$ is the iteration count. For Algorithm 2, we choose $\kappa_m = 10^{-6}$. For Algorithm 3, we choose $\kappa_m = 10^{-6}$, $\delta = 0.01$ and $|S_k| = \frac{20\log(d+3)}{\min\{\|\nabla f(\hat{z}_k)\|^2, \|\nabla f(z_k)\|^2\}}$. It is worth mentioning that $\min\{\|\nabla f(\hat{z}_k)\|^2, \|\nabla f(z_k)\|^2\}$ is used instead of $\|\nabla f(\hat{z}_k)\|^2$ for practical purpose and such choice does not violate our theoretical results. For the subproblem solving, we also apply the unit-stepsie Newton method as before.

In Figure 2, we compare Algorithm 3 with Algorithm 2 and stochastic first-order methods. Our results evidence that Algorithm 3 outperforms SEG/SOGDA in terms of solution quality: SEG and SOGDA barely move when Algorithm 3 still makes significant progress. Compared to Algorithm 2, Algorithm 3 achieves similar solution quality eventually but require fewer samples to output an acceptable solution. It is also worth noting that Algorithm 3 exhibits (super)-linear convergence as the iterate approaches the optimal solution regardless of subsampling and inexact subproblem solving. This intriguing property was rigorously justified for the subsampled Newton method in the optimization setting [Roosta-Khorasani and Mahoney, 2019], and it would be interesting to extend such results to min-max optimization.

6 Conclusion

We propose and analyze several inexact regularized Newton-type methods for finding a global saddle point of unconstrained convex-concave min-max optimization problems. Our methods are guaranteed to achieve the order-optimal iteration complexity of $O(\epsilon^{-2/3})$ and the tight complexity bound of $O((m + n)^\omega \epsilon^{-2/3} + (m + n)^2 \epsilon^{-2/3} \log \log(1/\epsilon))$ where $\omega \approx 2.3728$ is the matrix multiplication constant. In addition, we show that our general framework and analysis on these inexact methods can lead to the first class of subsampled Newton method for solving the finite-sum min-max optimization problems with order-optimal iteration complexity. Future research directions include the extension of our methods to structured nonconvex-nonconcave min-max optimization problems and the customized implementation of our methods in real application problems.
