DOUBLE VERONESE CONES WITH 28 NODES

HAMID AHMADINEZHAD, IVAN CHELTsov, JIHun PARK, CONSTANTIN SHRAMOV

Abstract. We study nodal del Pezzo 3-folds of degree 1 (also known as double Veronese cones) with 28
singularities, which is the maximal possible number of singularities for such varieties. We show that
they are in one-to-one correspondence with smooth plane quartics and use this correspondence to study
their automorphism groups. As an application, we find all $G$-birationally rigid varieties of this kind,
and construct an infinite number of non-conjugate embeddings of the group $S_4$ into the space Cremona
group.

1. Introduction

It is a common experience that varieties with the maximal possible number of singularities in a given
class have fascinating geometric properties. Classical examples of such varieties include the Burkhardt
quartic (see [dJSBVdV90], [CPS19]), the Segre cubic, and many others. The Segre cubic, which is
the unique three-dimensional cubic hypersurface with 10 isolated singular points, can be thought of
as a del Pezzo 3-fold. Recall that a del Pezzo 3-fold is a Fano 3-fold with at most terminal Gorenstein
singularities whose canonical class is divisible by 2 in the Picard group; in particular, the singularities
of such 3-folds are always isolated.

Del Pezzo 3-folds are classified according to their degrees, which are defined as the cubes of the
half-anticanonical classes. Such varieties with a maximal possible number of singularities were de-
scribed in [Pro13 Theorem 7.1]. The smaller degrees such del Pezzo 3-folds have, the more intriguing
their geometry is. Del Pezzo 3-folds of degree 4 can have at most six singularities, and there exists
a unique such variety with exactly six singular points. It has been studied in [Avi16]. There are
many works devoted to the geometry of the Segre cubic (see [Dol16, §2], [Fin87], [CS14, §5], [Avi18a],
and [Avi18b]). Del Pezzo 3-folds of degree 2 with 16 singular points, which is the maximal possible
number of singularities in this case, are quartic double solids branched along Kummer quartic sur-
faces. Thus their properties are closely related to those of the corresponding abelian surfaces. In
particular, such del Pezzo 3-folds are in one-to-one correspondence with smooth curves of genus 2 (see
for instance [Kem97, Propositions 1.2(i) and 1.3]).
The current paper studies the geometry of del Pezzo 3-folds of degree 1 with 28 singular points, which is the maximal possible number of singularities for such varieties (see [Pro13, Theorem 1.7] and [Pro13, Remark 1.8]). Each del Pezzo 3-fold of degree 1 is a hypersurface of degree six in the weighted projective space \( \mathbb{P}(1,1,1,2,3) \) (see [IP99, Theorem 3.2.5(i)]). This implies that it is a double cover of the cone over the Veronese surface in \( \mathbb{P}^5 \). For this reason, del Pezzo 3-folds of degree 1 are often called double Veronese cones.

Let \( V \) be a double Veronese cone with 28 singular points. Then \( -K_V \sim 2H \), where \( H \) is an ample Cartier divisor on \( V \) such that \( H^3 = 1 \). The existence of the following diagram was proven in [Pro13].

\[
\begin{array}{ccc}
\mathbb{P}^3 & \xrightarrow{\phi} & V \\
\downarrow \pi & & \downarrow \kappa \\
\mathbb{P}^3 & \dashrightarrow & \mathbb{P}^2
\end{array}
\]

In this diagram, \( \phi \) is a small resolution of all singular points of the 3-fold \( V \), the morphism \( \pi \) is the blow up of \( \mathbb{P}^3 \) at seven distinct points \( P_1, \ldots, P_7 \) that satisfy certain explicit generality conditions, the rational map \( \kappa \) is given by the linear system \( |H| \), and the rational map from \( \mathbb{P}^3 \) to \( \mathbb{P}^2 \) is given by the linear system (net) of quadrics passing through \( P_1, \ldots, P_7 \). Furthermore, Prokhorov implicitly verified in [Pro13] that each singular point of \( V \) is an isolated ordinary double point (a node).

Note that \( V \) is not \( \mathbb{Q} \)-factorial since \( \text{Cl}(V) \cong \mathbb{Z}^8 \) and \( \text{Pic}(V) \cong \mathbb{Z} \). Nevertheless, the class group \( \text{Cl}(V) \) can be naturally equipped with the intersection form:

\[
(D_1, D_2) = D_1 \cdot D_2 \cdot H
\]

for any two Weil divisors \( D_1 \) and \( D_2 \) on the 3-fold \( V \). Furthermore, Prokhorov proved in [Pro13, Theorem 1.7] (cf. [Pro13, Remark 1.8]) that the orthogonal complement to the canonical divisor \( K_V \) is the lattice \( \mathbb{E}_7 \) (cf. [DOSS, p. 107]). The same lattice appears in the Picard group of the double cover of \( \mathbb{P}^2 \) branched along a smooth plane quartic curve. This suggests a possible relation between double Veronese cones with 28 nodes and smooth plane quartic curves. As far as we know, such a relation was first pointed out in [DOSS, §IX.6]. A goal in the present paper is to make this relation precise and detailed.

The net of quadrics in (1.1) has exactly eight distinct base points, including the points \( P_1, \ldots, P_7 \); such a collection of eight points is called a regular Cayley octad (see Definition 3.3 for details). Moreover, the Hessian curve of this net is a smooth plane quartic curve, which we denote by \( C \). One can show that the isomorphism class of the curve \( C \) is independent of the choice of the commutative diagram (1.1). In fact, the curve \( C \) is projectively dual to the discriminant curve of the rational elliptic fibration \( \kappa \) (see [6] for details).

The first main result of the present paper is

**Theorem 1.3.** Assigning the curve \( C \) to the 3-fold \( V \) gives a one-to-one correspondence between the isomorphism classes of smooth plane quartic curves and the isomorphism classes of 28-nodal double Veronese cones.

Two alternative proofs of Theorem 1.3 will be presented in this paper. The first proof starts with a plane quartic curve \( C \) and produces an explicit equation that defines the corresponding 3-fold \( V \) in the weighted projective space \( \mathbb{P}(1,1,1,2,3) \) (see equation (5.10) and [5] for details). Another proof uses machinery from the theory of nets of quadrics to recover a commutative diagram (1.1) and check that the resulting 3-fold does not depend on the choices we have to make on the way.

Observe that for a given 28-nodal double Veronese cone the commutative diagram (1.1) is not unique. However, we can refine Theorem 1.3 to characterize all such diagrams in terms of the corresponding smooth plane quartic curve. Essentially, the diagram (1.1) depends only on the choice of seven distinct points \( P_1, \ldots, P_7 \) in \( \mathbb{P}^3 \) up to projective transformations. We will show that there are exactly 288 diagrams (1.1) up to projective transformations of \( \mathbb{P}^3 \) for a given general 28-nodal double Veronese
cone $V$, and will also give a way to compute the number of such diagrams for an arbitrary $V$ (see Corollaries 7.13 and 7.20). Here, the number $288 = 36 \cdot 8$ equals the number of even theta characteristics of $C$ times the number of choices for a point in the corresponding regular Cayley octad. In other words, it is the number of Aronhold systems on $C$. We refer the reader to [7] for details.

Note that there are other classical constructions that associate certain 3-folds to smooth plane quartics. We recall some of them in §10. It would be interesting to find the connections between these varieties and 28-nodal double Veronese cones.

The second result of the present paper is the following.

**Theorem 1.4.** One has

$$\text{Aut}(V) \cong \mu_2 \times \text{Aut}(C),$$

where the generator of the cyclic group $\mu_2$ of order 2 acts on $V$ by the Galois involution of the double cover of the Veronese cone.

We point out that Theorem 1.4 can be obtained from [DO88, IX.6] and Torelli theorem (see for instance [W57]). However, we provide a more elementary proof. Another advantage of our proof is its explicit nature, enabling an easier access to details of the group actions on the 3-folds, which will be useful later on when we study their birational properties.

Note that the commutative diagram (1.1) is not necessarily $\text{Aut}(V)$-equivariant. However, the rational map $\kappa$ in (1.1) always is. This gives a natural action of the group $\text{Aut}(V)$ on the plane $\mathbb{P}^2$. This action agrees with the direct product structure in Theorem 1.4 (see the proof of Theorem 1.4 in [6]).

The automorphism groups of smooth plane quartic curves are completely classified (see [Dol12, Theorem 6.5.2], [Hen76], or [KK79]). This gives us the full list of the automorphism groups of 28-nodal double Veronese cones.

**Example 1.5.** Let $C$ be the plane quartic curve given by

$$x^4 + y^4 + z^4 + \lambda(y^2 z^2 + x^2 z^2 + x^2 y^2) = 0,$$

where $\lambda$ is a constant different from $-2, 2,$ and $-1$ (in these three cases, the curves are singular). The corresponding 28-nodal double Veronese cone $V$ is the hypersurface of degree 6 in $\mathbb{P}(1,1,1,2,3)$ that is given by

$$w^2 = v^3 - g_4(s, t, u)v + g_6(s, t, u),$$

where $s, t, u, v$ and $w$ are weighted homogeneous coordinates on $\mathbb{P}(1,1,1,2,3)$ whose weights are equal to 1, 1, 1, 2 and 3, respectively. From (5) and Appendix A we obtain

$$g_4(s, t, u) = \frac{(\lambda^2 + 12)}{3}(s^4 + t^4 + u^4) + \frac{2(\lambda^2 + 6\lambda)}{3}(t^2 u^2 + s^2 u^2 + s^2 t^2)$$

and

$$g_6(s, t, u) = \frac{2(-\lambda^3 + 12\lambda^2 + 12\lambda)}{9}(t^4 u^2 + t^2 u^4 + s^4 u^2 + s^4 t^2 + s^2 t^4) + \frac{2(-\lambda^3 + 36\lambda)}{27}(s^6 + t^6 + u^6) + \frac{4(8\lambda^3 - 9\lambda^2 + 36)}{9}s^2 t^2 u^2.$$

Let $\mathfrak{G}$ be the subgroup in $\text{Aut}(V)$ that is generated by

$$[s : t : u : v : w] \mapsto [-s : -t : u : v : w],$$

$$[s : t : u : v : w] \mapsto [u : s : t : v : w],$$

$$[s : t : u : v : w] \mapsto [t : s : u : v : -w].$$

Then $\mathfrak{G} \cong \mathfrak{S}_4$. Let $\tau \in \text{Aut}(V)$ be the Galois involution of the double cover of the Veronese cone. If $\lambda \neq 0$ and $\lambda^2 + 3\lambda + 18 \neq 0$, then $\tau$ and $\mathfrak{G}$ generate the group

$$\text{Aut}(V) \cong \mu_2 \times \mathfrak{S}_4.$$
conjugate to the subgroup \( G \)

\[ \text{the Picard groups of the double covers of } P \]

Whether \( E \)

does not seem to be straightforward. We discuss this phenomenon in Corollary 1.9.

It follows from (1.1) that 28-nodal double Veronese cones are rational. Thus, their automorphism groups are embedded into the space Cremona group, that is the group of birational selfmaps of \( P^3 \).

For a given subgroup \( G \subset \text{Aut}(V) \), to study its conjugacy class in the space Cremona group, one should understand \( G \)-equivariant birational geometry of the 3-fold \( V \). From this point of view, the most interesting groups \( G \) are such that \( \text{rk Cl}(V)^G = 1 \), and \( V \) is \( G \)-birationally (super-)rigid (see [CS16, Definition 3.1.1]). In this paper, we prove

**Theorem 1.7.** Let \( V \) be a 28-nodal double Veronese cone and \( G \) be a subgroup of \( \text{Aut}(V) \). Then the following four conditions are equivalent:

1. \( \text{rk Cl}(V)^G = 1 \) and \( V \) is \( G \)-birationally rigid;
2. \( \text{rk Cl}(V)^G = 1 \) and \( V \) is \( G \)-birationally super-rigid;
3. \( \text{rk Cl}(V)^G = 1 \) and \( G \) does not fix any point in \( P^2 \);
4. \( V \) is a double Veronese cone from Example 1.5 and \( G \) contains the subgroup \( \mathfrak{S} \).

It is known that the plane Cremona group, that is the group of birational selfmaps of \( P^2 \), contains an infinite number of non-conjugate subgroups isomorphic to the symmetric group \( \mathfrak{S}_4 \) (see [Di09, §8], and cf. [DiM19, Theorem 1.5]). Theorem 1.7 implies the following result.

**Corollary 1.8.** The space Cremona group contains an infinite number of non-conjugate subgroups isomorphic to \( \mathfrak{S}_4 \).

It is known from [CS12] and [Ahm17, Theorem 2.2] that the space Cremona group contains at least four non-conjugate subgroups isomorphic to \( \text{PSL}_2(F_7) \). Applying Theorem 1.7 to the case of the Klein quartic curve, we obtain

**Corollary 1.9.** The space Cremona group contains at least five non-conjugate subgroups isomorphic to \( \text{PSL}_2(F_7) \).

Let \( V \) be the 3-fold from Example 1.5. Then \( \text{Aut}(V) \) contains a subgroup \( \mathfrak{S}' \cong \mathfrak{S}_4 \) that is not conjugate to the subgroup \( \mathfrak{S} \). The subgroup \( \mathfrak{S}' \) is generated by

\[ [s : t : u : v : w] \mapsto [-s : -t : u : v : w], \]
\[ [s : t : u : v : w] \mapsto [u : s : t : v : w], \]
\[ [s : t : u : v : w] \mapsto [t : s : u : v : w]. \]

In §2 we show that there exists a \( \mathfrak{S}' \)-equivariant birational map \( V \dasharrow X \), where \( X \) is a del Pezzo 3-fold of degree 2 with 16 singular points such that \( \text{rk Cl}(X)^{\mathfrak{S}'} = 1 \). It would be interesting to determine whether \( X \) is \( \mathfrak{S}' \)-birationally rigid or not (cf. [Avi19]).

We have established a relation between 28-nodal double Veronese cones and smooth plane quartics. Despite this establishment, the connection between the \( E_7 \) lattices appearing in their class groups and the Picard groups of the double covers of \( P^2 \) branched in the corresponding smooth quartic curves does not seem to be straightforward. We discuss this phenomenon in §10.

The plan of the paper is as follows. In §2 we collect several auxiliary results that will be used later in our proofs. In §3 we recall some assertions concerning nets of quadrics in \( P^3 \). The base points of the nets of quadrics described therein will be utilized in order to construct 28-nodal double Veronese cones in §4. This construction is originally due to [Pro13]. In §5 we construct a 28-nodal double Veronese cone starting from a smooth plane quartic curve. We also provide an explicit equation (5.10) for such
a 3-fold in terms of covariants of the quartic. In §6 we put the previous results together to establish a one-to-one correspondence between 28-nodal double Veronese cones and smooth plane quartics, which proves Theorem 1.3. Also, in §6 we study the automorphism groups of 28-nodal double Veronese cones and prove Theorem 1.4. In §7 we give an alternative proof of Theorem 1.3. Also, in §7 we study the automorphism groups of 28-nodal double Veronese cones and prove Theorem 1.4. In §7 we give an alternative proof of Theorem 1.3. Also, in §7 we prove Corollary 7.19 which relates commutative diagrams (1.1) with even theta characteristics on the smooth plane quartic. In §8 we investigate the $S_4$-equivariant birational geometry of double Veronese cones introduced in Example 1.5, and, in particular, describe the action of the group $S_4$ on their Weil divisor class groups. In §9 we study $G$-birationally rigid nodal double Veronese cones and prove Theorem 1.7. In §10 we discuss some open questions concerning 28-nodal double Veronese cones. Finally, in Appendix A we collect some formulae allowing to construct explicit equations of 28-nodal double Veronese cones from the equations of plane quartics.

Acknowledgements. The authors are grateful to Fabrizio Catanese, Igor Dolgachev, Alexander Kuznetsov, Marco Pacini, and Yuri Prokhorov for inspiring discussions. Part of this work was done during their stay at the Erwin Schrödinger International Institute for Mathematics and Physics in Vienna in August 2018. They are grateful to the institute for excellent working conditions. Jihun Park would also like to thank Adrien Dubouloz for his hospitality at Institut de Mathématiques de Bourgogne in August 2019, where he worked on finalizing the paper. Constantin Shramov was supported by the HSE University Basic Research Program, Russian Academic Excellence Project 5-100, by the Young Russian Mathematics award, and by the Foundation for the Advancement of Theoretical Physics and Mathematics “BASIS”.

2. Preliminaries

In this section we collect several auxiliary results that will be used later in our proofs. The following fact is well known to experts. It was pointed out to us by Alexander Kuznetsov. This will be utilized in §4.

Lemma 2.1 (cf. [CS16, Remark 4.2.7]). Let $Y$ be a smooth variety, $C$ be a smooth curve on $Y$, and $P$ be a point on $C$. Let $\pi: \tilde{Y} \to Y$ be the blow up of $Y$ at $P$, and let $\tilde{C}$ be the proper transform of $C$ on $\tilde{Y}$. Then

$$N_{\tilde{C}/\tilde{Y}} \cong N_{C/Y}(-P).$$

Proof. The differential of the morphism $\pi$ provides the morphisms $d\pi: T_{\tilde{C}/\tilde{Y}} \to \pi^*T_{C/Y}$ and $d\pi: N_{\tilde{C}/\tilde{Y}} \to \pi^*N_{C/Y}$. They can be included into the following commutative diagram:

$$
\begin{array}{cccc}
0 & \longrightarrow & T_{\tilde{C}} & \longrightarrow & T_{\tilde{C}/\tilde{Y}} & \longrightarrow & N_{\tilde{C}/\tilde{Y}} & \longrightarrow & 0 \\
0 & \longrightarrow & \pi^*T_C & \longrightarrow & \pi^*T_{C/Y} & \longrightarrow & \pi^*N_{C/Y} & \longrightarrow & 0.
\end{array}
$$

Let $E$ be the exceptional divisor of $\pi$. Note that the fiber of $N_{\tilde{C}/\tilde{Y}}$ over the point $\tilde{P} = \tilde{C} \cap E$ is identified with the tangent space to $E$ at $\tilde{P}$. Since the differential $d\pi$ vanishes on the latter space, we conclude that the morphism $d\pi: N_{\tilde{C}/\tilde{Y}} \to \pi^*N_{C/Y}$ factors through the morphism

$$\theta: N_{\tilde{C}/\tilde{Y}} \to \pi^*N_{C/Y}(-k\tilde{P})$$

for some positive integer $k$. Comparing the degrees of these vector bundles, we conclude that $k = 1$. Now $\theta$ is a morphism of vector bundles of the same rank and degree, and it is an isomorphism over a general point of $\tilde{C}$. This implies that $\theta$ is an isomorphism. \qed
Corollary 2.2. Let $L$ be a line in $\mathbb{P}^3$, and let $P_1, P_2$ be two points on $L$. Let $\pi: \widehat{\mathbb{P}}^3 \to \mathbb{P}^3$ be the blow up of $\mathbb{P}^3$ at $P_1$ and $P_2$, and denote by $\widehat{L}$ the proper transform of $L$ on $\widehat{\mathbb{P}}^3$. Then

$$\mathcal{N}_{\widehat{L}/\widehat{\mathbb{P}}^3} \cong \mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1).$$

Corollary 2.3. Let $C$ be a twisted cubic curve in $\mathbb{P}^3$, and let $P_1, \ldots, P_6$ be six distinct points on $C$. Let $\pi: \widehat{\mathbb{P}}^3 \to \mathbb{P}^3$ be the blow up at the points $P_1, \ldots, P_6$, and denote by $\widehat{C}$ the proper transform of $C$ on $\widehat{\mathbb{P}}^3$. Then

$$\mathcal{N}_{\widehat{C}/\widehat{\mathbb{P}}^3} \cong \mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1).$$

Proof. Note that

$$\mathcal{N}_{\widehat{C}/\widehat{\mathbb{P}}^3} \cong \mathcal{O}_{\mathbb{P}^1}(5) \oplus \mathcal{O}_{\mathbb{P}^1}(5),$$

(see [EvdV98] Proposition 6). It remains to apply Lemma 2.4. \qed

In §9 we will need the following auxiliary result that is a special equivariant version of a result of Kawakita (see [Kaw01] Theorem 1.1]).

Lemma 2.4. Let $Y$ be a $3$-fold, and let $P$ be its smooth point. Let $G$ be a subgroup of $\text{Aut}(Y)$ that fixes the point $P$. Let $\mathcal{M}_Y$ be a $G$-invariant mobile linear system on $Y$. Suppose that $P$ is a center of non-canonical singularities of the log pair $(Y, \lambda \mathcal{M}_Y)$ for some rational number $\lambda$. If the Zariski tangent space $T_{P,Y}$ is an irreducible representation of the group $G$, then

$$\text{mult}_P(\mathcal{M}_Y) > \frac{2}{\lambda}.$$

Proof. Suppose that $\text{mult}_P(\mathcal{M}_Y) \leq \frac{2}{\lambda}$. Let us show that $T_{P,Y}$ is a reducible representation of the group $G$. Let $\sigma: \hat{Y} \to Y$ be the blow up at the point $P$, let $E$ be the $\sigma$-exceptional surface, and let $\mathcal{M}_{\hat{Y}}$ be the proper transform of the linear system $\mathcal{M}_Y$ via $\sigma$. Then

$$K_{\hat{Y}} + \lambda \mathcal{M}_{\hat{Y}} + \left(\lambda \text{mult}_P(\mathcal{M}_Y) - 2\right)E \sim \mathbb{Q} \sigma^*(K_Y + \lambda \mathcal{M}_Y),$$

so that $E$ contains a non-canonical center of the log pair $(\hat{Y}, \lambda \mathcal{M}_{\hat{Y}})$. Then $E$ contains a non-log canonical center of the log pair $(\hat{Y}, E + \lambda \mathcal{M}_{\hat{Y}})$. It then follows from the inversion of adjunction (for instance, see [KM98] Theorem 5.50) that $(E, \lambda \mathcal{M}_{\hat{Y}}|_E)$ is not log canonical.

Let $\mu$ be the positive rational number such that $(E, \mu \mathcal{M}_{\hat{Y}}|_E)$ is strictly log canonical. Then $\mu < \lambda$, so that $\mu \text{mult}_P(\mathcal{M}_Y) < 2$. On the other hand, we have

$$(2.5) \quad \mu \mathcal{M}_{\hat{Y}}|_E \sim \mathbb{Q} \mu \text{mult}_P(\mathcal{M}_Y)L,$$

where $L$ is a line in $E \cong \mathbb{P}^2$.

Let $Z$ be a log canonical center of the pair $(E, \mu \mathcal{M}_{\hat{Y}}|_E)$. If $Z$ is a curve, then the multiplicity of the restriction $\mu \mathcal{M}_{\hat{Y}}|_E$ at this curve is at least 1 by [KSC04] Exercise 6.18, so that (2.5) implies that $Z$ is a line. The same arguments imply that other curves in $E$ cannot be log canonical centers of the pair $(E, \mu \mathcal{M}_{\hat{Y}}|_E)$ simultaneously with $Z$ in this case, so that $Z$ is $G$-invariant. This implies that $T_{P,Y}$ is a reducible representation of the group $G$.

To complete the proof, we may assume that the locus of log canonical singularities of the log pair $(E, \mu \mathcal{M}_{\hat{Y}}|_E)$ consists of finitely many points. On the other hand, it follows from (2.5) that the divisor $-(K_E + \mu \mathcal{M}_{\hat{Y}}|_E)$ is ample. Thus, using Kollár–Shokurov connectedness principle (for example, see [KM98] Corollary 5.49]), we see that this locus is connected. Then it consists of one point. This again means that $T_{P,Y}$ is a reducible representation of the group $G$. \qed

The following two lemmas will also be used in §9.

Lemma 2.6. Let $G$ be a finite group acting on $\mathbb{P}^2$ without fixed points. If a $G$-orbit on $\mathbb{P}^2$ has at least four points, then it contains four points such that no three of them are collinear.
Proof. Let Σ be a $G$-orbit with at least four points. The $G$-action has no invariant line, otherwise it would have a fixed point outside the invariant line. Thus Σ contains at least three non-collinear points, say, $P_1$, $P_2$, and $P_3$. For each $i = 1, 2, 3$ denote by $L_i$ the line determined by the two points $\{P_1, P_2, P_3\} \setminus \{P_i\}$. If Σ contains a point outside $L_1 \cup L_2 \cup L_3$, then we are done. Suppose that this is not a case. Let $R_1$ be a point of Σ different from $P_1$, $P_2$, and $P_3$. We may assume that $R_1 \in L_1$. Since the line $L_1$ is not $G$-invariant, there is a line $L'_1$ different from $L_1$ and containing three points of Σ. We are then able to choose four distinct points of $\Sigma \setminus (L_1 \cap L'_1)$ that lie on $L_1$ or $L'_1$. Such four points satisfy the desired property. □

Lemma 2.7. Let $G$ be a finite group acting on $\mathbb{P}^2$ without fixed points. Suppose that there is a $G$-invariant smooth quartic curve $C$ in $\mathbb{P}^2$. Then

- the curve $C$ is given by equation (1.6);
- the group $G$ contains a subgroup isomorphic to $\mathfrak{S}_4$;
- the projective plane $\mathbb{P}^2$ can be identified with a projectivization of an irreducible three-dimensional representation of $\mathfrak{S}_4$.

Proof. The list of all groups preserving plane quartics together with the equations of the corresponding quartics can be found in [Dol12, Theorem 6.5.2], [Hen76], or [KK79]. Thus, it remains to check which of them have fixed points on $\mathbb{P}^2$. □

3. FROM ARONHOLD HEPTADS TO SMOOTH PLANE QUARTICS

In this section we present some auxiliary assertions concerning nets of quadrics in $\mathbb{P}^3$. The theory of nets of quadrics is a classical subject. We refer the reader to [Bea77], [Edg37a], [Edg37b], [Edg38], [Edg41], [Edg42], [Wal78], [Wal81], [DOS88], [Dol12, §6.3.2], [Tyu75], [Rei72], and references therein for many aspects of this theory.

For seven distinct points $P_1, \ldots, P_7$ in $\mathbb{P}^3$ denote by $\mathcal{L}(P_1, \ldots, P_7)$ the linear system of the quadrics passing through the points $P_1, \ldots, P_7$ in $\mathbb{P}^3$.

Before we proceed, let us employ a simple assertion that tells us the dimension of $\mathcal{L}(P_1, \ldots, P_7)$.

Lemma 3.1. Let $P_1, \ldots, P_r$ be points in a zero-dimensional complete intersection of three quadric surfaces in $\mathbb{P}^3$.

- If $r \leq 7$, then the $r$ points $P_1, \ldots, P_r$ impose independent conditions on quadric surfaces.
- If $r = 8$, then they do not impose independent conditions on quadric surfaces.

Proof. The first assertion immediately follows from [EGH96, Conjecture CB11]. The conjecture is partially proven in [EGH96, 2.2], which allows us to apply it to our case. The second assertion is obvious since the eight points form a complete intersection of three quadric surfaces. □

The following assertion is a key observation that connects 28-nodal double Veronese cones and nets of quadrics in $\mathbb{P}^3$.

Lemma 3.2 (cf. [DO88, Lemma IX.5]). For seven distinct points $P_1, \ldots, P_7$ in $\mathbb{P}^3$, the two conditions

(A) every element of $\mathcal{L}(P_1, \ldots, P_7)$ is irreducible;
(B) the base locus of $\mathcal{L}(P_1, \ldots, P_7)$ consists of eight distinct points,

are satisfied if and only if the following three conditions hold:

(A') no four points of $P_1, \ldots, P_7$ are coplanar (and in particular no three are collinear);
(B') all points $P_1, \ldots, P_7$ are not contained in a single twisted cubic;
(C') for each $i$, the twisted cubic passing through the points of $\{P_1, \ldots, P_7\} \setminus \{P_i\}$ and the line passing through the point $P_i$ and one point in $\{P_1, \ldots, P_7\} \setminus \{P_i\}$ meet neither twice nor tangentially.
Choose two general quadric surfaces that contain both the points $P_1, \ldots, P_7$ must contain this twisted cubic. Thus, the base locus of $L(P_1, \ldots, P_7)$ is one-dimensional, which contradicts condition (A). Therefore, condition (A') holds.

Suppose that for some $i, j$, say $i = 1$, $j = 2$, the twisted cubic curve $C$ passing through the six points $P_2, \ldots, P_7$ and the line $L$ passing through $P_1$ and $P_2$ meet at $P_2$ and at some point $P$. If they meet tangentially at $P_2$, then we put $P = P_2$. Since the linear system of quadric surfaces containing $C$ is two-dimensional, there are two distinct quadric surfaces $Q_1$ and $Q_2$ that contain the curve $C$ and the point $P_1$. Note that $Q_1$ and $Q_2$ belong to the linear system $L(P_1, \ldots, P_7)$. The intersection of $Q_1$ and $Q_2$ is a curve of degree 4 that contains the curve $C$. Since $L$ passes through three points $P_1, P_2,$ and $P$ of $Q_i, i = 1, 2$, it must be contained in $Q_i, i = 1, 2$. Therefore, the intersection of $Q_1$ and $Q_2$ consists of $C$ and $L$. This implies that for an element $Q$ in $L(P_1, \ldots, P_7)$, the intersection of the quadrics $Q_1$, $Q_2$ and $Q$ either is a curve or consists of 7 points (i.e., $P_1 + 2P_2 + P_3 + \ldots + P_7$), which gives a contradiction to condition (B). Therefore, condition (C') holds.

Now assume that conditions (A'), (B'), and (C') hold.

Suppose that there is a reducible member in $L(P_1, \ldots, P_7)$. Then it consists of two planes containing the seven points $P_1, \ldots, P_7$. Then one of the planes must contain four of the seven points, which is a contradiction to condition (A'). Therefore, condition (A) must be satisfied.

Suppose that condition (B) does not hold, i.e., the support of the base locus of $L(P_1, \ldots, P_7)$ either consists of only seven points or contains a curve. Note that dim $L(P_1, \ldots, P_7) \geq 2$.

Let $C$ be the twisted cubic curve passing through the six points $P_2, \ldots, P_7$. Then there are two distinct quadric surfaces $Q_1$ and $Q_2$ that contain the curve $C$ and the point $P_1$. They are elements of $L(P_1, \ldots, P_7)$. The intersection of $Q_1$ and $Q_2$ consists of the twisted cubic curve $C$ and a line $L$. Since $C$ does not contain the point $P_1$ by condition (B'), the line $L$ must contain $P_1$. Note that $L$ intersects $C$ twice or tangentially.

If the base locus of $L(P_1, \ldots, P_7)$ is zero-dimensional, then we choose an element $Q_3$ of $L(P_1, \ldots, P_7)$ that contains neither $C$ nor $L$. The intersection of the quadrics $Q_1$, $Q_2$ and $Q_3$ then consists of the seven points $P_1, \ldots, P_7$ set-theoretically. Otherwise it would consists of eight points including $P_1, \ldots, P_7$, and every element in $L(P_1, \ldots, P_7)$ would pass through the eight intersection points by Lemma 3.1. Since the three quadric surfaces meet at eight points counted with multiplicities, the line $L$ and $C$ must meet at one of the six points $P_2, \ldots, P_7$; otherwise $Q_3$ would contain either $C$ or $L$. This is a contradiction to condition (C') since $L$ meets $C$ twice or tangentially.

If the base locus of $L(P_1, \ldots, P_7)$ contains a curve, then for an arbitrary member $Q$ in $L(P_1, \ldots, P_7)$ the intersection of the quadrics $Q_1$, $Q_2$ and $Q$ contains either $C$ or $L$. Since the dimension of the linear system of quadrics containing both $C$ and $P_1$ is 1, the base locus of $L(P_1, \ldots, P_7)$ cannot contain $C$. Choose two general quadric surfaces that contain both the point $P_7$ and the twisted cubic curve passing through $P_1, \ldots, P_6$. They are elements in $L(P_1, \ldots, P_7)$. Therefore, their intersection consists of the twisted cubic curve passing through the points $P_1, \ldots, P_6$, and the line $L$. Therefore, $L$ must meet $C$ at $P_7$. This contradicts condition (C') since $L$ and $C$ meet twice or tangentially. Therefore, condition (B) holds. \qed

**Definition 3.3.** A set of seven distinct points $P_1, \ldots, P_7$ in $\mathbb{P}^3$ is called an *Aronhold heptad* if every element of $L(P_1, \ldots, P_7)$ is irreducible and the base locus of $L(P_1, \ldots, P_7)$ consists of eight distinct points. The set of such eight distinct points is called a *regular Cayley octad*. To be precise, the seven points $P_1, \ldots, P_7$ are called an Aronhold heptad of the regular Cayley octad.
For an Aronhold heptad $P_1, \ldots, P_7$ in $\mathbb{P}^3$, Lemma 3.1 immediately implies that there exists a unique regular Cayley octad that contains $P_1, \ldots, P_7$. It also shows that the linear system $L(P_1, \ldots, P_7)$ is a net. Conversely, seven points of a regular Cayley octad always form an Aronhold heptad.

**Lemma 3.4.** Let $P_1, \ldots, P_8$ be a regular Cayley octad in $\mathbb{P}^3$. For all $1 \leq i < j \leq 8$, denote by $L_{ij}$ the line passing through the points $P_i$ and $P_j$, and denote by $T_{ij}$ the twisted cubic passing through the six points of $\{P_1, \ldots, P_8\} \setminus \{P_i, P_j\}$. Let $L_{ij}$ be the linear subsystem of $L(P_1, \ldots, P_8)$ that consists of the quadrics passing through $T_{ij}$. Then $L_{ij}$ is a pencil, and the base locus of $L_{ij}$ is the union $T_{ij} \cup L_{ij}$.

**Proof.** The first assertion follows from Lemma 3.1. To prove the second assertion, note that the base locus of $L_{ij}$ is a union of $T_{ij}$ and some line. On the other hand, the base locus must contain all the points $P_1, \ldots, P_8$. Since the twisted cubic $T_{ij}$ passes neither through $P_i$ nor through $P_j$, the line in the base locus of $L_{ij}$ must pass through both of these points, i.e., this line must be $L_{ij}$. □

Suppose that we are given seven points $P_1, \ldots, P_7$ in $\mathbb{P}^3$ such that $\dim L(P_1, \ldots, P_7) = 2$. Then there are three linearly independent quadric homogeneous polynomials $F_0, F_1, F_2$ over $\mathbb{P}^3$ that generate the linear system $L(P_1, \ldots, P_7)$, i.e., an element in $L(P_1, \ldots, P_7)$ is defined by the quadric homogeneous equation

$$xf_0 + yf_1 + zf_2 = 0$$

for some $[x : y : z] \in \mathbb{P}^2$. We can express (3.5) as a $4 \times 4$ symmetric matrix $M(P_1, \ldots, P_7)$ with entries of linear forms in $x, y, z$. Then $\det(M(P_1, \ldots, P_7)) = 0$ defines a plane quartic curve $H(P_1, \ldots, P_7)$ in $\mathbb{P}^2$. This plane quartic curve is called the **Hessian quartic** of the net $L(P_1, \ldots, P_7)$.

**Remark 3.6.** The hypersurface $\mathcal{D}$ in $\mathbb{P}(\text{Sym}(4, \mathbb{C})) \cong \mathbb{P}^9$ defined by the determinant polynomial is singular exactly at non-zero $4 \times 4$ symmetric matrices of coranks at least 2. The three linearly independent quadric homogeneous polynomials $F_0, F_1, F_2$ determine a plane $\Pi(F_0, F_1, F_2)$ in $\mathbb{P}(\text{Sym}(4, \mathbb{C}))$. Therefore, the plane quartic curve $H(P_1, \ldots, P_7)$ is singular if and only if the plane $\Pi(F_0, F_1, F_2)$ either passes through a point corresponding to a non-zero $4 \times 4$ symmetric matrix of corank at least 2, or tangentially intersects the hypersurface $\mathcal{D}$ at a point corresponding to a $4 \times 4$ symmetric matrix of corank 1.

**Lemma 3.7.** Seven distinct points $P_1, \ldots, P_7$ in $\mathbb{P}^3$ form an Aronhold heptad if and only if the linear system $L(P_1, \ldots, P_7)$ is a net and the plane quartic curve $H(P_1, \ldots, P_7)$ is smooth. Moreover, every smooth plane quartic curve can be obtained in this way.

**Proof.** Assume that the plane quartic curve $H(P_1, \ldots, P_7)$ is singular. Since the net $L(P_1, \ldots, P_7)$ does not contain any reducible member, it follows from Remark 3.6 that the plane $\Pi(F_0, F_1, F_2)$ tangentially intersects the hypersurface $\mathcal{D}$ at a point corresponding to a $4 \times 4$ symmetric matrix of corank 1 in $\mathbb{P}(\text{Sym}(4, \mathbb{C}))$. We may assume that $F_0$ corresponds to such a $4 \times 4$ symmetric matrix of corank 1. Denote by $A_0, A_1, A_2$ the $4 \times 4$ symmetric matrices corresponding to $F_0, F_1, F_2$, respectively. We may also assume that the matrix $A_0$ is a diagonal matrix with the last diagonal entry 0. Since the lines $xA_0 + yA_1$ and $xA_0 + zA_2$ in $\mathbb{P}(\text{Sym}(4, \mathbb{C}))$ tangentially intersect the surface $\mathcal{D}$ at $A_0$, both the entry of $A_1$ at the 4th row and the 4th column and the entry of $A_2$ at the 4th row and the 4th column are zero. This means that the point $[0 : 0 : 0 : 1]$ is a base point of $L(P_1, \ldots, P_7)$. However, $F_0$ is singular at $[0 : 0 : 0 : 1]$, and hence the base locus of $L(P_1, \ldots, P_7)$ cannot consist of eight distinct points. This means that the points $P_1, \ldots, P_7$ do not form an Aronhold heptad.

Now assume that the curve $H(P_1, \ldots, P_7)$ is smooth. Suppose that the net $L(P_1, \ldots, P_7)$ contains a reducible member. Then the plane $\Pi(F_0, F_1, F_2)$ passes through a point corresponding to a non-zero $4 \times 4$ symmetric matrix of corank at least 2, and hence $H(P_1, \ldots, P_7)$ is singular by Remark 3.6, which gives a contradiction.

Suppose that the base locus of $L(P_1, \ldots, P_7)$ is not zero-dimensional. It then must be one-dimensional. Furthermore, each irreducible curve $B$ of the base locus must be of degree at most 3 since $L(P_1, \ldots, P_7)$ is a net.
If $B$ is a line, then there is a point $P_i$ outside $B$. Let $\Pi$ be the plane determined by $B$ and $P_i$. Each quadric from $\mathcal{L}(P_1, \ldots, P_7)$ cuts out in $\Pi$ the line $B$ and a line passing through $P_i$. Such lines form at most a pencil. Therefore, there is a member in $\mathcal{L}(P_1, \ldots, P_7)$ containing $\Pi$, which leads to a contradiction.

If $B$ is a conic, two members in $\mathcal{L}(P_1, \ldots, P_7)$ intersect along $B$ and another conic $B'$. Then either $B$ or $B'$ must contain four points of $P_1, \ldots, P_7$. This again implies that there is a reducible member in $\mathcal{L}(P_1, \ldots, P_7)$ and leads to a contradiction.

If $B$ is a cubic curve, two members in $\mathcal{L}(P_1, \ldots, P_7)$ intersect along $B$ and a line. Since a line cannot contain more than two points of $P_1, \ldots, P_7$, the curve $B$ must contain at least 5 points of $P_1, \ldots, P_7$. If $B$ is singular, then $B$ is planar, and hence $\mathcal{L}(P_1, \ldots, P_7)$ contains a reducible member. Therefore, $\mathcal{L}(P_1, \ldots, P_7)$ must be the net determined by the twisted cubic $B$. In such a case, we can directly show that $H(P_1, \ldots, P_7)$ is singular.

Consequently, the base locus of $\mathcal{L}(P_1, \ldots, P_7)$ is zero-dimensional. Suppose that the base locus of $\mathcal{L}(P_1, \ldots, P_7)$ does not consist of eight distinct points. Then there is a point $P_i$, say $P_1$, with the following property: three general elements in $\mathcal{L}(P_1, \ldots, P_7)$ meet at $P_1$ so that their local intersection index at $P_1$ is at least 2. This implies that there is an element in $\mathcal{L}(P_1, \ldots, P_7)$ singular at $P_1$, and hence $H(P_1, \ldots, P_7)$ cannot be smooth. Indeed, we may assume that the singular quadric is defined by a $4 \times 4$ diagonal matrix $A_0$ with the 4th diagonal entry equal to zero. The singular point $P_1$ is located at $[0 : 0 : 0 : 1]$. Then the net $\mathcal{L}(P_1, \ldots, P_7)$ can be generated by the net of $4 \times 4$ symmetric matrices

$$xA_0 + yA_1 + zA_2,$$

where $A_1$ and $A_2$ are $4 \times 4$ symmetric matrices each of which has 0 for the entry at the 4th row and the 4th column. Then

$$\det(xA_0 + yA_1 + zA_2) = 0$$

defines a quartic curve singular at $[1 : 0 : 0 : 0]$. The obtained contradiction shows that the base locus of $\mathcal{L}(P_1, \ldots, P_7)$ consists of eight distinct points, so that $P_1, \ldots, P_7$ form an Aronhold heptad.

A given smooth quartic curve can be defined by the determinant of a $4 \times 4$ symmetric linear matrix. This fact together with the first assertion of the lemma implies the second assertion. □

Remark 3.8. The representation of a smooth plane quartic as the determinant of a symmetric linear matrix that we used in the proof of Lemma 3.7 goes back to 1855 (see [Hes55]) and 1902 (see [Dix02]). For a contemporary proof, see [Bea00, Proposition 4.2].

The following well-known fact concerning intersections of quadrics in $\mathbb{P}^3$ will be necessary for the present paper. It should be remarked here that they have been extensively researched in [Rei72] and [Tro75] in much wider settings.

Lemma 3.9. Let $Q_1$ and $Q_2$ be two distinct quadrics in $\mathbb{P}^3$ and $E$ be the intersection of $Q_1$ and $Q_2$. Then the following are equivalent.

- the intersection $E$ is smooth and of codimension 2 in $\mathbb{P}^3$.
- The line $\mathcal{L}$ determined by $Q_1$ and $Q_2$ in $\mathbb{P}(\text{Sym}(4, \mathbb{C})) \cong \mathbb{P}^9$ intersects the determinant hypersurface $\mathcal{D}$ (see Remark 3.6) at four distinct points.
- After a suitable linear coordinate change, $E$ can be defined by the equations

$$x_0^2 + x_1^2 + x_2^2 + x_3^2 = \lambda_0 x_0^2 + \lambda_1 x_1^2 + \lambda_2 x_2^2 + \lambda_3 x_3^2 = 0$$

in $\mathbb{P}^3$, where $\lambda_i$’s are four distinct constants.

If these equivalent conditions hold, then the intersection $E$ is isomorphic to the double cover of the line $\mathcal{L}$ in $\mathbb{P}(\text{Sym}(4, \mathbb{C}))$ branched exactly at the four intersection points $\mathcal{L} \cap \mathcal{D}$.

Proof. The equivalence immediately follows from [Rei72, Proposition 2.1]. As a matter of fact, the last statement is also instantly implied by the result in [Rei72, Theorem 4.8] that deals with much
more general situation. However, in $\mathbb{P}^3$, the conditions for [Rei72, Theorem 4.8] turn into a tangible state, so that an elementary and short proof could be presented as follows.

Suppose that $E$ is defined in $\mathbb{P}^3$ by the equations

$$x_0^2 + x_1^2 + x_2^2 + x_3^2 = \lambda_0 x_0^2 + \lambda_1 x_1^2 + \lambda_2 x_2^2 + \lambda_3 x_3^2 = 0$$

for some four distinct constants $\lambda_0, \ldots, \lambda_3$. To complete the proof, it is enough to show that $E$ is isomorphic to a double cover of $\mathbb{P}^1$ branched at four distinct points whose cross-ratio is

$$(3.10) \quad \frac{(\lambda_1 - \lambda_3)(\lambda_2 - \lambda_0)}{(\lambda_1 - \lambda_0)(\lambda_2 - \lambda_3)}$$

modulo permutation. Note that $\lambda_0 \neq \lambda_i$ for $1 \leq i \leq 3$ because $E$ is smooth. Rewrite the equations of $E$ as

$$x_0^2 + x_1^2 + x_2^2 + x_3^2 = (\lambda_0 - \lambda_1)x_1^2 + (\lambda_0 - \lambda_2)x_2^2 + (\lambda_0 - \lambda_3)x_3^2 = 0.$$

We first consider the projection of $E$ to the plane $\Pi$ defined by $x_0 = 0$ centered at the point $[1 : 0 : 0 : 0]$. The image is the conic $R$ defined by

$$(\lambda_0 - \lambda_1)x_1^2 + (\lambda_0 - \lambda_2)x_2^2 + (\lambda_0 - \lambda_3)x_3^2 = 0$$

on $\Pi$. Furthermore, $E$ is a double cover of $R$. Let $[0 : \alpha : \beta : \gamma]$ be a point on this conic. The equation

$$\mu^2 + \nu^2(\alpha^2 + \beta^2 + \gamma^2) = 0$$

in $[\mu : \nu] \in \mathbb{P}^1$ determines the points $[\mu : \nu \alpha : \nu \beta : \nu \gamma]$ of $E$ over the point $[0 : \alpha : \beta : \gamma]$. Therefore, the double cover is branched at $[0 : \alpha : \beta : \gamma]$ if and only if

$$\alpha^2 + \beta^2 + \gamma^2 = 0.$$

Consequently, the four branch points on $R$ are the intersection points of the conics

$$x_1^2 + x_2^2 + x_3^2 = 0,$$

$$\lambda_1 x_1^2 + \lambda_2 x_2^2 + \lambda_3 x_3^2 = 0$$

on $\Pi$. These four points are $[0 : \sqrt{\lambda_3 - \lambda_2} : \pm \sqrt{\lambda_1 - \lambda_3} : \pm \sqrt{\lambda_2 - \lambda_1}]$.

We now consider the projection of $R$ centered at the point $[0 : \sqrt{\lambda_0 - \lambda_2} : \sqrt{\lambda_1 - \lambda_0} : 0]$ to the line $L$ defined by $x_1 = 0$ on $\Pi$. This projection defines an isomorphism of $R$ onto $L$. Therefore, $E$ is the double cover of $L$ branched at the points

$$[0 : 0 : \sqrt{\lambda_3 - \lambda_2} \sqrt{\lambda_1 - \lambda_0} \pm \sqrt{\lambda_0 - \lambda_2} \sqrt{\lambda_1 - \lambda_3} : \pm \sqrt{\lambda_0 - \lambda_2} \sqrt{\lambda_1 - \lambda_3}] .$$

It is easy to check that the cross-ratio of the above four points

$$\pm \sqrt{\lambda_3 - \lambda_2} \sqrt{\lambda_1 - \lambda_0} \pm \sqrt{\lambda_0 - \lambda_2} \sqrt{\lambda_1 - \lambda_3}$$

is equal to the desired number $(3.10)$ modulo permutation. This completes the proof. \qed

For an Aronhold heptad $P_1, \ldots, P_7$, the projective plane $\mathbb{P}^2$ projectively dual to the net of quadrics $\mathcal{L}(P_1, \ldots, P_7) \cong \mathbb{P}^2$ can be identified with the base of the elliptic fibration $\mathbf{x}$ that is obtained from $\mathbb{P}^3$ by blowing up the points of the corresponding regular Cayley octad. It is well-known that the projectively dual curve of the Hessian quartic curve can be interpreted in terms of singular fibers of $\mathbf{x}$. Namely, we have the following

**Lemma 3.11.** Let $P_1, \ldots, P_7$ be an Aronhold heptad, and let $\hat{H} \subset \mathbb{P}^2$ be the curve parameterizing singular fibers of $\mathbf{x}$. Then $\hat{H}$ is projectively dual to $H(P_1, \ldots, P_7)$. 

Proof. Choose a fiber $\tilde{E}$ of the elliptic fibration $\pi$. It is the proper transform of an intersection curve $E$ of two quadrics in $\mathcal{L}(P_1, \ldots, P_7)$. Furthermore, the fiber $\tilde{E}$ is smooth if and only if the intersection curve $E$ is smooth because it cannot be singular at the points of the regular Cayley octad. On the other hand, Lemma 3.3 implies that the intersection curve $E$ is smooth if and only if the corresponding pencil of quadrics contains exactly four singular quadrics. This verifies that the projectively dual curve of $\tilde{H}$ coincides with the Hessian curve of the net $\mathcal{L}(P_1, \ldots, P_7)$. \hfill \square

4. FROM ARONHOLD HEPTADS TO DOUBLE VERONESE CONES

In this section we review the birational construction of 28-nodal double Veronese cones due to [Pro13].

The following result is mainly a part of [Pro13, Theorem 7.1]. We provide its proof for the reader’s convenience and for clarification.

Proposition 4.1. Let $P_1, \ldots, P_7$ be seven points in $\mathbb{P}^3$ that form an Aronhold heptad. Let $\pi: \mathbb{P}^3 \to \mathbb{P}^3$ be the blow up of $\mathbb{P}^3$ at the points $P_1, \ldots, P_7$, and let $\phi: \mathbb{P}^3 \to V$ be the map given by the linear system $|−2K_{\mathbb{P}^3}|$. Then

- the map $\phi$ is a birational morphism;
- the exceptional locus of $\phi$ is a disjoint union of the proper transforms of the lines passing through pairs of the points $P_i$ and the twisted cubics passing through six-tuples of the points $P_i$;
- the variety $V$ is a 28-nodal double Veronese cone.

Proof. Note that by Lemma 3.2 there are 21 lines passing through pairs of the points $P_i$, and 7 twisted cubic curves passing through six-tuples of the points $P_i$. Furthermore, due to Lemma 3.2 their proper transforms on $\mathbb{P}^3$ are disjoint. It is easy to see that these proper transforms intersect the anticanonical class of $\mathbb{P}^3$ trivially.

We claim that any other irreducible curve intersects the anticanonical class neither trivially nor negatively. To see this, let $L$ be an irreducible curve on $\mathbb{P}^3$ whose proper transform on $\mathbb{P}^3$ nonpositively intersects the anticanonical class of $\mathbb{P}^3$. It means

$$\sum_{i=1}^{7} \text{mult}_{P_i}L \geq 2\deg(L). \tag{4.2}$$

Choose a point $P$ on $L$ other than the base point of $\mathcal{L}(P_1, \ldots, P_7)$. Then the quadric surfaces in $\mathcal{L}(P_1, \ldots, P_7)$ passing through the extra point $P$ form a pencil. It follows from (4.2) that every quadric surface in this pencil contains the curve $L$. If $\deg L = 4$, then we see from (1.2) that $L$ must be singular at some of the points $P_i$. This means that the intersection of three quadrics from $\mathcal{L}(P_1, \ldots, P_7)$ is not reduced at that point, i.e., the base locus of $\mathcal{L}(P_1, \ldots, P_7)$ consists of less than 8 points, which is a contradiction. If $\deg L = 2$, then $L$ is a conic, and by (1.2) it contains four of the points $P_i$. This is impossible by Lemma 3.2. Therefore, one has either $\deg L = 3$ or $\deg L = 1$. If $L$ is a singular cubic curve, then it is planar. However, (1.2) implies that it contains at least four of the points $P_i$. This is impossible by Lemma 3.2. Therefore, $L$ is either a twisted cubic or a line. In both cases we see from (1.2) that $L$ is one of the above 28 curves.

Let $\tilde{\phi}$ be the morphism defined by the linear system $|−nK_{\mathbb{P}^3}|$ for large enough $n$. Now Corollaries 2.2 and 2.3 imply that $\tilde{\phi}$ is a flopping contraction, which implies that $\tilde{\phi}$ satisfies the properties of the first and the second assertions. They also verify that the 28 proper transforms are contracted to 28 nodes on $V$. Since $\mathbb{P}^3$ is a smooth weak Fano 3-fold and $\tilde{\phi}$ contracts all the curves that trivially intersect the anticanonical class of $\mathbb{P}^3$, the 3-fold $V$ is a Fano 3-fold with exactly 28 singular points.

Let $Q$ be a quadric surface passing through the Aronhold heptad, then

$$-K_{\mathbb{P}^3} \sim 2(\pi^*(Q) - (F_1 + \ldots + F_7)).$$

12
where $F_i$’s are the exceptional surfaces of $\pi$. This shows that $-K_V$ is divisible by 2. Since
\[ (-K_V)^3 = (-K_{\tilde{\mathbb{P}^3}})^3 = 8, \]
the variety $V$ is a del Pezzo 3-fold of degree 1. Now it is easy to check that the divisor $-2K_V$

is very ample, which implies that the morphism $\tilde{\phi}$ coincides with the map $\phi$ defined by the linear system $| -2K_{\tilde{\mathbb{P}^3}}|$. This completes the proof.

The following observation was explained to us by Yuri Prokhorov.

**Example 4.3.** Let $C$ be a twisted cubic in $\mathbb{P}^3$. Choose six distinct points $P_1, \ldots, P_6$ on $C$. Let $P$

be a point on $C$ different from $P_1, \ldots, P_6$, and let $L$ be the line passing through $P_6$ and $P$. Choose

a point $P_7 \in L \setminus \{P_6, P\}$. Then such seven points cannot be an Aronhold heptad since they violate

the conditions in Lemma 3.2. Furthermore, if we define the 3-folds $\tilde{\mathbb{P}^3}$ and $V$ and the map $\phi$ as in

Proposition 4.1, then $\phi$ contracts (in particular) the proper transforms of $C$ and $L$ on $\tilde{\mathbb{P}^3}$. These curves

are not disjoint, which implies that the 3-fold $V$ is not nodal. The same holds if $L$ is chosen to be a
tangent line at the point $P_6$ to $C$.

The following result is implicitly contained (but not clearly stated) in [Pro13]. It is implied by the
results of [Pro13] together with a simple additional observation.

**Theorem 4.4.** Let $V$ be a double Veronese cone with 28 singular points. Then $V$ can be constructed

from some Aronhold heptad as in Proposition 4.1.

**Proof.** It first follows from [Pro13, Theorem 1.7] and [Pro13, Remark 1.8] that the rank of the divisor

class group of $V$ is 8. Then [Pro13, Theorem 7.1(i)] implies that $V$ can be obtained in the same way as in Proposition 4.1

with seven points of $\mathbb{P}^3$ such that no four of them are coplanar. It remains to verify that the seven points form an Aronhold heptad. However, [Pro13, Theorem 7.1(ii)] shows that having 28 singular points is equivalent to $(A')$, $(B')$, and $(C')$ in Lemma 3.2. Therefore, the seven

points in the construction must form an Aronhold heptad by Lemma 3.2.

Proposition 4.4 and Theorem 4.4 immediately imply the following

**Corollary 4.5.** If a double Veronese cone has 28 singular points, then they are all nodes.

We conclude this section with another result that is a part of [Pro13, Theorem 7.1]. Its proof is

similar to that of Proposition 4.1.

**Proposition 4.6.** Let $P_1, \ldots, P_6$ be six points in $\mathbb{P}^3$ such that no four of them are coplanar.

Let $\pi: \tilde{\mathbb{P}^3} \to \mathbb{P}^3$ be the blow up of $\mathbb{P}^3$ at the points $P_1, \ldots, P_6$, and let $\phi: \tilde{\mathbb{P}^3} \to W$ be the map
given by the linear system $| -K_{\tilde{\mathbb{P}^3}}|$. Then

- the map $\phi$ is a birational morphism;
- the exceptional locus of $\phi$ is a disjoint union of the proper transforms of the lines passing through pairs of the points $P_i$ and the twisted cubic passing through all the points $P_i$;
- the variety $W$ is a 16-nodal double cover of $\mathbb{P}^3$ branched over a quartic surface.

5. FROM SMOOTH PLANE QUARTICS TO DOUBLE VERONESE CONES

In this section we construct a 28-nodal double Veronese cone starting from a smooth plane quartic curve. We also provide an explicit equation (5.10) for such a 3-fold in terms of covariants of the plane quartic curve.

Let $\mathbb{P}^2$ be the dual of the projective plane $\mathbb{P}^2$. We use a homogeneous coordinate system $[x : y : z]$ for $\mathbb{P}^2$ and $[s : t : u]$ for $\mathbb{P}^2$.

We start with a smooth quartic curve $C$ in the projective plane $\mathbb{P}^2$ given by an equation

\[ (5.1) \quad H(x, y, z) = \sum_{i+j+k=4} a_{ijk} x^i y^j z^k = 0. \]
We regard \([s : t : u]\) as a general point in \(\mathbb{P}^2\). Then the corresponding line on \(\mathbb{P}^2\) is a general line \(L_{s,t,u}\) given by
\[
sx + ty + uz = 0.
\]
The line \(L_{s,t,u}\) hits the quartic \(C\) at four distinct points \(x_1, x_2, x_3, x_4\) lying on \(L_{s,t,u} \setminus \{z = 0\}\). We may regard these four points as points on the affine line, so that we could define their cross-ratio as follows:
\[
\lambda(x_1, x_2, x_3, x_4) = \frac{(x_1 - x_3)(x_4 - x_2)}{(x_1 - x_2)(x_4 - x_3)}.
\]
This has six different values according to the order of the four points. However, the following \(j\)-function is invariant with respect to the reordering \(x_1, x_2, x_3, x_4\).

\[
j(x_1, x_2, x_3, x_4) = 256 \frac{(1 - \lambda(x_1, x_2, x_3, x_4) (1 - \lambda(x_1, x_2, x_3, x_4)))^3}{\lambda(x_1, x_2, x_3, x_4)^2 (1 - \lambda(x_1, x_2, x_3, x_4))^2}
\]
\begin{equation}
= 2^8 \frac{(x_1 - x_2)(x_4 - x_3)^2 - (x_1 - x_3)(x_4 - x_2)(x_4 - x_1)(x_3 - x_2))^3}{(x_1 - x_2)^2(x_1 - x_3)^2(x_1 - x_4)^2(x_2 - x_3)^2(x_2 - x_4)^2(x_3 - x_4)^2}.
\end{equation}

(5.2)

By plugging \(z = -\frac{sx + ty}{u}\) into (5.1), we obtain
\[
u^4 H(x, y, -\frac{sx + ty}{u}) = \sum_{i+j+k=4} a_{ijk} (-u)^{4-k} (sx + ty)^k x^i y^j
\]
\begin{equation}
= \sum_{r=0}^{4} b_{4-r} x^r y^{4-r},
\end{equation}
(5.3)

where
\[
b_r = \sum_{j=0}^{r} \sum_{i+k=4-j} (-1)^k a_{ijk} \left(\frac{k}{k+j-r}\right) s^{k+j-r} t^{r-j} u^{4-k}.
\]

Then we have the following identities for elementary symmetric functions of \(x_1, x_2, x_3, x_4\):
\[
x_1 + x_2 + x_3 + x_4 = -\frac{b_1}{b_0};
\]
\[
x_1 x_2 + x_1 x_3 + x_1 x_4 + x_2 x_3 + x_2 x_4 + x_3 x_4 = \frac{b_2}{b_0};
\]
\[
x_2 x_3 x_4 + x_1 x_2 x_4 + x_1 x_2 x_3 + x_1 x_2 x_3 = -\frac{b_3}{b_0};
\]
\[
x_1 x_2 x_3 x_4 = \frac{b_4}{b_0}.
\]

Since the denominator and the numerator of the \(j\)-function in (5.2) are symmetric polynomials in \(x_1, x_2, x_3, x_4\), the \(j\)-function in (5.2) may be regarded as a rational function in \(b_0, b_1, b_2, b_3, b_4\). Indeed, one has
\[
j(b_0, b_1, b_2, b_3, b_4) = 1728 \frac{4h_2(b_0, b_1, b_2, b_3, b_4)^3}{4h_2(b_0, b_1, b_2, b_3, b_4)^3 - 27h_3(b_0, b_1, b_2, b_3, b_4)^2},
\]
where
\[
h_2(b_0, b_1, b_2, b_3, b_4) = \frac{1}{3} \left(-3b_1 b_3 + 12b_0 b_4 + b_2^2\right);
\]
\[
h_3(b_0, b_1, b_2, b_3, b_4) = \frac{1}{27} \left(72b_0 b_2 b_4 - 27b_0 b_3^2 - 27b_4^2 b_4 + 9b_1 b_2 b_3 - 2b_2^3\right)
\]
(see Appendix A for a more detailed computation).
Regarding $h_2(b_0, b_1, b_2, b_3, b_4)$ and $h_3(b_0, b_1, b_2, b_3, b_4)$ as polynomials in $s, t, u$, we see from Appendix A that

\[ h_2(b_0, b_1, b_2, b_3, b_4) = u^4 g_4(s, t, u), \]
\[ h_3(b_0, b_1, b_2, b_3, b_4) = u^6 g_6(s, t, u), \]

where $g_4(s, t, u)$ and $g_6(s, t, u)$ are homogeneous polynomials of degrees 4 and 6, respectively, in $s, t, u$. Consequently, the rational function $j(b_0, b_1, b_2, b_3, b_4)$ may be regarded as a rational function $j_C$ in $s, t, u$, so that it is a rational function on $\mathbb{P}^2$. More precisely, one has

\[ j_C(s, t, u) = \frac{4g_4(s, t, u)^3}{4g_4(s, t, u)^3 - 27g_6(s, t, u)^2}. \]

**Remark 5.5.** The equation $g_4(s, t, u) = 0$ of degree 4 describes the points of $\mathbb{P}^2$ corresponding to lines that intersect $C$ by equianharmonic quadruples of points (see for instance [Dol12] §2.3.4 for terminology). In other words, lines with the quadruples of points define elliptic curves of $j$-invariant 0. Elliptic curves of $j$-invariant 0 are isomorphic to the Fermat plane cubic curve. Similarly, the equation $g_6(s, t, u) = 0$ of degree 6 describes the points of $\mathbb{P}^2$ corresponding to lines that intersect $C$ by harmonic quadruples of points. In this case, lines with the quadruples of points define elliptic curves of $j$-invariant 1728. Note that neither the cross-ratio nor the $j$-invariant is defined for the lines corresponding to the 24 intersection points (counted with multiplicities) of $g_4(s, t, u) = 0$ and $g_6(s, t, u) = 0$.

**Lemma 5.6.** The $j$-function $j_C(s, t, u)$ is not constant. In particular, $g_4(s, t, u)$ cannot be a zero polynomial.

**Proof.** Among the lines on $\mathbb{P}^2$, there are both tangent lines to $C$ and non-tangent lines to $C$. This implies that the $j$-function, which is defined by the cross-ratios of the intersection points, is not constant.

We can use the polynomials $g_4(s, t, u)$ and $g_6(s, t, u)$ to write down the equation of the projectively dual curve of the plane quartic $C$.

**Proposition 5.7.** The equation

\[ 4g_4(s, t, u)^3 - 27g_6(s, t, u)^2 = 0 \]

of degree 12 defines the projectively dual curve $\tilde{C}$ of the quartic curve $C$ in $\mathbb{P}^2$.

**Proof.** The curve $\tilde{C}$ has degree 12. By construction the rational function $j_C(s, t, u)$ is well-defined at least outside the projectively dual curve $\tilde{C}$. On the other hand, we know from Lemma 5.6 that $g_4(s, t, u)$ is not a zero polynomial. Thus it follows from (5.4) that $j_C(s, t, u)$ has poles along the curves defined by some of the factors of $4g_4(s, t, u)^3 - 27g_6(s, t, u)^2$. These poles must be contained in the projectively dual curve $\tilde{C}$. Since $\tilde{C}$ is an irreducible curve of degree 12, it must be defined by the homogeneous equation (5.8) of degree 12.

Recall that a bitangent line to the quartic curve $C$, which is not a tangent line at a hyper-inflection point of $C$, yields an ordinary double point on the projectively dual curve $\tilde{C}$. Meanwhile, the tangent line to $C$ at an ordinary inflection point of $C$ produces an ordinary cusp in $\tilde{C}$ and the tangent line to $C$ at a hyper-inflection point of $C$ generates a triple point of $\tilde{C}$ that is analytically isomorphic to a singularity defined by equation $s^3 = t^4$. These are all the possible types of singularities of $\tilde{C}$.

Let $C_4$ be the quartic curve defined by $g_4(s, t, u) = 0$, and let $C_6$ be the sextic curve defined by $g_6(s, t, u) = 0$ in $\mathbb{P}^2$.

**Lemma 5.9.** Let $P$ be an intersection point of the curves $C_4$ and $C_6$. Then one of the following possibilities occur.

- The curves $C_4$ and $C_6$ are smooth at $P$, and meet transversally at $P$; in this case $P$ is an ordinary cusp of the curve $\tilde{C}$.
The curve $C_6$ has a double point at $P$ and the local intersection index of $C_4$ and $C_6$ at $P$ is 2; in this case $P$ is a triple point of $\tilde{C}$ analytically isomorphic to $s^3 = t^4$.

Proof. The point $P$ is a singular point of $\tilde{C}$. The defining equation (5.8) of $\tilde{C}$ shows that $C_4$ is smooth at $P$ and that $P$ cannot be an ordinary double point of $\tilde{C}$. Thus $\tilde{C}$ has either an ordinary cusp or a triple point analytically isomorphic to $s^3 = t^4$ at $P$. Note that $P$ is a triple point of $\tilde{C}$ if and only if $C_6$ is singular at $P$. Furthermore, in such a case, $P$ must be a double point of $C_6$.

The defining equation (5.8) tells that $P$ is an ordinary cusp of $\tilde{C}$ if $C_4$ and $C_6$ are transversal at $P$. On the other hand, if $C_6$ is smooth and tangent to $C_4$ at $P$, then $\tilde{C}$ has a double point worse than a simple cusp at $P$, in the sense that its log canonical threshold is smaller than 5/6.

We now suppose that $P$ is a double point of $C_6$. Then, (5.8) shows that $\tilde{C}$ has a triple point at $P$. Therefore, to complete the proof, it is enough to show that the singularity of $\tilde{C}$ at $P$ cannot be a triple point analytically isomorphic to $s^3 = t^4$ if the tangent line to $C_4$ at $P$ is one of the Zariski tangent lines of $C_6$ at $P$. This can be easily checked by blowing up. Indeed, if the tangent line to $C_4$ at $P$ is one of the Zariski tangent lines of $C_6$ at $P$, then the proper transform of $\tilde{C}$ via the blow up of $\mathbb{P}^2$ at $P$ is still singular at some point over $P$, which is not the case for the singularity $s^3 = t^4$.

We now consider the hypersurface $V$ of degree 6 in $\mathbb{P}(1,1,1,2,3)$ given by an equation

$$w^2 + v^3 - g_4(s,t,u)v + g_6(s,t,u) = 0,$$

where $\text{wt}(w) = 3, \text{wt}(v) = 2$. We denote by $F(s,t,u,v,w)$ the left hand side of (5.10), and set

$$G(s,t,u) = 4g_4(s,t,u)^3 - 27g_6(s,t,u)^2.$$ 

Then $G(s,t,u) = 0$ defines the projectively dual curve $\tilde{C}$ of the smooth quartic curve $C$ in $\mathbb{P}^2$ by Proposition 5.7.

Denote by $V^{\text{sing}}_v$ the set of singular points of $V$ in the section by $v = 0$ and by $V^{\text{sing}}_o$ the set of singular points of $V$ outside the section by $v = 0$. On the other hand, denote by $\tilde{C}^{\text{sing}}_o$ the set of singular points of $\tilde{C}$ at which $C_6$ is singular, and denote by $\tilde{C}^{\text{sing}}_v$ the set of singular points of $\tilde{C}$ outside $C_6$.

Lemma 5.11. Define the maps as follows:

$$\tilde{C}^{\text{sing}}_o \rightarrow V^{\text{sing}}_o,$$

$$[a_0 : a_1 : a_2] \mapsto [a_0 : a_1 : a_2 : \frac{3g_6(a_0,a_1,a_2)}{2g_4(a_0,a_1,a_2)} : 0];$$

$$\tilde{C}^{\text{sing}}_v \rightarrow V^{\text{sing}}_v,$$

$$[a_0 : a_1 : a_2] \mapsto [a_0 : a_1 : a_2 : 0 : 0].$$

Then both are one-to-one correspondences.

Proof. Let $[a_0 : a_1 : a_2]$ be a point in the set $\tilde{C}^{\text{sing}}_o$. Observe that $g_6(a_0,a_1,a_2) \neq 0$, and hence $g_4(a_0,a_1,a_2) \neq 0$. Since $[a_0 : a_1 : a_2] \in \tilde{C}^{\text{sing}}_o$, we have

$$\frac{\partial F}{\partial v} (a_0,a_1,a_2) = \frac{3g_6(a_0,a_1,a_2)}{2g_4(a_0,a_1,a_2)} \neq 0.$$ 

Also, since

$$12g_4(a_0,a_1,a_2)^2 \frac{\partial g_4}{\partial s} (a_0,a_1,a_2) - 54g_6(a_0,a_1,a_2) \frac{\partial g_6}{\partial s} (a_0,a_1,a_2) = 0,$$
Moreover, we have
\[
\frac{\partial F}{\partial s}(a_0, a_1, a_2, \frac{3g_6(a_0, a_1, a_2)}{2g_4(a_0, a_1, a_2)}, 0) = -\frac{3g_6(a_0, a_1, a_2)}{2g_4(a_0, a_1, a_2)} \frac{\partial g_1}{\partial s}(a_0, a_1, a_2) + \frac{\partial g_6}{\partial s}(a_0, a_1, a_2)
\]
\[
= -\frac{27g_6(a_0, a_1, a_2)^2}{4g_4(a_0, a_1, a_2)^3} \frac{\partial g_6}{\partial s}(a_0, a_1, a_2) + \frac{\partial g_6}{\partial s}(a_0, a_1, a_2) = 0.
\]
Similarly, we see that \(\frac{\partial F}{\partial t}\) and \(\frac{\partial F}{\partial u}\) vanish at the point \([a_0 : a_1 : a_2 : \frac{3g_6(a_0, a_1, a_2)}{2g_4(a_0, a_1, a_2)} : 0]\), so that this point belongs to \(V_{o}^{\text{sing}}\).

Conversely, suppose that \([a_0 : a_1 : a_2 : v_0 : w_0]\) belongs to \(V_{o}^{\text{sing}}\). Then \(w_0 = 0\) and \(v_0 \neq 0\). Furthermore, taking the partial derivative of (5.10) with respect to \(v\), we obtain
\[g_4(a_0, a_1, a_2) = 3v_0^2.\]
Using (5.10) again, we get
\[g_6(a_0, a_1, a_2) = -v_0^3 + v_0g_4(a_0, a_1, a_2) = 2v_0^3.\]
Then
\[
\frac{\partial G}{\partial s}(a_0, a_1, a_2) = 12g_4(a_0, a_1, a_2)^2 \frac{\partial g_4}{\partial s}(a_0, a_1, a_2) - 54g_6(a_0, a_1, a_2) \frac{\partial g_6}{\partial s}(a_0, a_1, a_2)
\]
\[
= 108v_0^4 \frac{\partial g_4}{\partial s}(a_0, a_1, a_2) - 108v_0^3 \frac{\partial g_6}{\partial s}(a_0, a_1, a_2) = -108v_0^3 \frac{\partial F}{\partial s}(a_0, a_1, a_2, v_0, w_0) = 0.
\]
Similarly we obtain
\[\frac{\partial G}{\partial t}(a_0, a_1, a_2) = \frac{\partial G}{\partial u}(a_0, a_1, a_2) = 0.\]
This implies that \([a_0 : a_1 : a_2]\) belongs to \(C_{o}^{\text{sing}}\).

Suppose that \([a_0 : a_1 : a_2]\) is in \(C_{o}^{\text{sing}}\). Then
\[\frac{\partial g_6}{\partial s}(a_0, a_1, a_2) = \frac{\partial g_6}{\partial t}(a_0, a_1, a_2) = \frac{\partial g_6}{\partial u}(a_0, a_1, a_2) = 0.\]
Moreover, we have \(g_6(a_0, a_1, a_2) = 0\), and thus also \(g_4(a_0, a_1, a_2) = 0\). These imply
\[\frac{\partial F}{\partial v}(a_0, a_1, a_2, 0, 0) = \frac{\partial F}{\partial u}(a_0, a_1, a_2, 0, 0) = 0,
\]
\[\frac{\partial F}{\partial s}(a_0, a_1, a_2, 0, 0) = \frac{\partial F}{\partial t}(a_0, a_1, a_2, 0, 0) = \frac{\partial F}{\partial u}(a_0, a_1, a_2, 0, 0) = 0.
\]
Therefore, \([a_0 : a_1 : a_2 : 0 : 0]\) lies in \(V_{v}^{\text{sing}}\).

Conversely, suppose that \([a_0 : a_1 : a_2 : 0 : 0]\) belongs to \(V_{v}^{\text{sing}}\). Then
\[0 = \frac{\partial F}{\partial v}(a_0, a_1, a_2, 0, 0) = -g_4(a_0, a_1, a_2).
\]
In particular, this gives \(g_6(a_0, a_1, a_2) = 0\). We have
\[0 = \frac{\partial F}{\partial s}(a_0, a_1, a_2, 0, 0) = \frac{\partial g_6}{\partial s}(a_0, a_1, a_2),
\]
\[0 = \frac{\partial F}{\partial t}(a_0, a_1, a_2, 0, 0) = \frac{\partial g_6}{\partial t}(a_0, a_1, a_2),
\]
\[0 = \frac{\partial F}{\partial u}(a_0, a_1, a_2, 0, 0) = \frac{\partial g_6}{\partial u}(a_0, a_1, a_2).
\]
Therefore, we conclude that the point \([a_0 : a_1 : a_2]\) belongs to \(C_{v}^{\text{sing}}\). \(\square\)

**Theorem 5.12.** The del Pezzo 3-fold \(V\) has exactly 28 singular points.
Proof. Let $\delta_o$ be the number of the ordinary bitangent lines, i.e., lines tangent to $C$ at two distinct points, of the smooth quartic curve $C$, and let $\delta_s$ be the number of the hyper-inflection points of the smooth quartic curve $C$. The tangent line to $C$ at a hyper-inflection point is a bitangent line to $C$ that is tangent to $C$ at a single point with multiplicity 4. Let $\iota$ be the number of ordinary inflection points of $C$. Then we can derive

$$\delta_o + \delta_s = 28, \quad \iota + 2\delta_s = 24$$

from the classical Plücker formulae (for instance, see [GH78 §2.4]). In particular, the projectively dual curve $\tilde{C}$ has exactly

$$\delta_o + \delta_s + \iota = 52 - 2\delta_s$$

singular points.

The ordinary bitangent lines define $\delta_o$ ordinary double points on $\tilde{C}$. Such singular points cannot lie on $C_6$. If so, then they would also lie on $C_4$ by Proposition 5.7 and would not be ordinary double points of $\tilde{C}$ by Lemma 5.9.

Meanwhile, by Lemma 5.9 the curves $C_4$ and $C_6$ meet

- either transversally
- or in such a way that $C_6$ has a double point at $P$, and the local intersection index of $C_4$ and $C_6$ at $P$ is 2.

Furthermore, intersection points of the former type yield ordinary cusps, and ones of the latter type produce triple points analytically isomorphic to $s^3 = t^4$. The number of intersection points of the former type is $\iota$ and the number of intersection points of the latter type is $\delta_s$. We may then conclude that

$$\# |\tilde{C}_o^{\text{sing}}| = \delta_o, \quad \# |\tilde{C}_v^{\text{sing}}| = \delta_s.$$ 

Since $\delta_o + \delta_s = 28$, Lemma 5.11 immediately implies the statement.

The following assertion can be deduced from Theorem 5.12 and Corollary 4.5. However, we present a computational proof here to show how the singularities of $\tilde{C}$ and the singularities of $V$ interact with each other.

**Proposition 5.13.** The singular points of the del Pezzo 3-fold $V$ are all ordinary double points.

**Proof.** Let $P$ be a point in $V_v^{\text{sing}}$. After a suitable coordinate changes, we may assume that

$$P = [0 : 0 : 1 : 0 : 0].$$

By Lemmas 5.9 and 5.11 the curve $C_4$ is smooth at $[0 : 0 : 1]$, the curve $C_6$ has a double point at $[0 : 0 : 1]$, and the local intersection index of $C_4$ and $C_6$ at $[0 : 0 : 1]$ equals to 2. We may also assume that the tangent line to $C_4$ at $[0 : 0 : 1]$ is defined by $s = 0$ and the Zariski tangent cone of $C_6$ at $[0 : 0 : 1]$ is defined by $t(t + \alpha s) = 0$, where $\alpha$ is a (possibly zero) constant. Put

$$f(s, t, v, w) = F(s, t, 1, v, w), \quad g(s, t) = G(s, t, 1),$$

$$\tilde{g}_4(s, t, v, w) = g_4(s, t, 1), \quad \tilde{g}_6(s, t, v, w) = g_6(s, t, 1).$$

We regard $s, t, v, w$ as local coordinates around the point $P$ that corresponds to the origin in $\mathbb{C}^4$, which we denote by $p$. We then consider the Hessian of $f$ at the point $p$:

$$\text{Hess}(f)(p) = 2 \left( \frac{\partial \tilde{g}_4}{\partial s}(p) \right)^2 \frac{\partial^2 \tilde{g}_6}{\partial s^2}(p) \neq 0.$$ 

This implies that the point $P$ is an ordinary double point of $V$.

We now consider a point $R$ in $V_v^{\text{sing}}$. By appropriate coordinate changes, we may assume that

$$R = [0 : 0 : 1 : v_0 : 0],$$

where $v_0$ is a non-zero constant. In the affine chart defined by $u \neq 0$ in $\mathbb{P}(1, 1, 1, 2, 3)$, the point $R$ corresponds to $q = (0, 0, v_0, 0)$. In the affine chart defined by $u \neq 0$ in $\mathbb{P}^2$, we denote by $o$ the origin.
Since $q$ is a singular point of the hypersurface defined by $f = 0$, we conclude that $o$ is a singular point of the curve defined by $g = 0$ by Lemma [5.11]. Furthermore, since $q$ is from $V_{\text{sing}}$, the origin $o$ is an ordinary double point of $g = 0$. From this one can obtain the following relations:

\[ v_0 = \frac{3g_6(q)}{2g_4(q)}, \quad 27 (\tilde{g}_6(q))^3 = 4 (g_4(q))^3, \]
\[ 3g_6(q) \frac{\partial g_6}{\partial t}(q) = 2\tilde{g}_4(q) \frac{\partial g_4}{\partial t}(q), \quad 3\tilde{g}_6(q) \frac{\partial \tilde{g}_6}{\partial t}(q) = 2g_4(q) \frac{\partial g_4}{\partial t}(q), \]
\[ 9\tilde{g}_6(q) \frac{\partial \tilde{g}_6}{\partial s}(q) = 2\tilde{g}_4(q) 2\frac{\partial g_4}{\partial s}(q), \quad 9\tilde{g}_6(q) \frac{\partial \tilde{g}_6}{\partial t}(q) = 2\tilde{g}_4(q) 2\frac{\partial g_4}{\partial t}(q). \]

Using them, we are able to derive

\[ 48 (\tilde{g}_4(q))^4 \text{Hess}(f)(q) = -\tilde{g}_6(q) \text{Hess}(g)(o). \]

(Since the computation for this is messy and tedious, it is omitted.) The point $[0 : 0 : 1]$ is an ordinary double point of $C$, so that $\text{Hess}(g)(o) \neq 0$. This completes the proof. \hfill \□

Below, we list several particular examples of 28-nodal double Veronese cones constructed from smooth plane quartics with interesting automorphism groups (cf. [D109], Table 6). In each case the 3-fold is given by equation [5.10].

**Example 5.14.** We consider the Klein quartic for $C$. It is given by the equation

\[ x^3y + y^3z + z^3x = 0. \]

Its automorphism group is isomorphic to $\text{PSL}_2(\mathbb{F}_7)$. We have $g_4(s, t, u) = s^3t + t^3u + u^3s$ and $g_6(s, t, u) = \frac{1}{8} (3s^5u - 15s^2t^2u^2 + 3st^5 + 3tu^5).$

**Example 5.15.** Let $C$ be the Fermat plane quartic curve defined by

\[ x^4 + y^4 + z^4 = 0. \]

Its automorphism group is isomorphic to $\mu_4^2 \rtimes \mathfrak{S}_3$. We have $g_4(s, t, u) = 4(s^4 + t^4 + u^4)$ and $g_6(s, t, u) = 16s^2t^2u^2$.

For explicit equations of smooth plane quartics with an action of the symmetric group $\mathfrak{S}_4$ and the corresponding 28-nodal double Veronese cones we refer the reader to Example [1.5].

**Example 5.16.** Suppose that the smooth quartic curve $C$ is given by

\[ x^4 + y^4 + z^4 + x^3y + 2x^3z = 0. \]

Then $C$ has no non-trivial automorphisms. We have $g_4(s, t, u) = (s^4 - st^3 - 2su^3 + t^4 + u^4)$ and $g_6(s, t, u) = -16s^3t^2u - 8s^3u^2 + 16s^2t^2u^2 - 4t^6 + 4t^5u - t^4u^2 - 4t^2u^4 + 4tu^5 - u^6$.  

6. ONE-TO-ONE CORRESPONDENCE

In the present section we put the previous results together to establish a one-to-one correspondence between 28-nodal double Veronese cones and smooth plane quartics, which is asserted in Theorem [1.3]. We also study automorphism groups of 28-nodal double Veronese cones and prove Theorem [1.4].

In this section, for the projective plane we keep the same two notations as in [5], i.e., $\mathbb{P}^2$ with a homogeneous coordinate system $[x : y : z]$ and its projectively dual plane $\mathbb{P}^2$ with $[s : t : u]$.

**Remark 6.1.** For an arbitrary del Pezzo 3-fold of degree 1, let $\kappa: V \rightarrow \mathbb{P}^2$ be the rational map given by the half-anticanonical linear system on $V$. The half-anticanonical linear system has a unique base point. The 3-fold $V$ is smooth at the base point, so that a general fiber of $\kappa$ is an elliptic curve by Bertini theorem and adjunction formula.

In the remaining part of this section we use $\kappa$ to denote the rational half-anticanonical elliptic fibration on a double Veronese cone $V$.

Now we construct a smooth plane quartic from a 28-nodal double Veronese cone.
Lemma 6.2. Let $V$ be a 28-nodal double Veronese cone. Denote by $C$ the discriminant curve of the rational elliptic fibration $\kappa$, and let $\mathcal{C}$ be the projectively dual curve of $C$. Then $C$ is a smooth plane quartic. Furthermore, for any construction of $V$ from an Aronhold heptad as in Proposition 4.1, the curve $C$ is isomorphic to the Hessian curve of the corresponding net of quadrics.

Proof. It follows from Theorem 4.4 that $V$ can be constructed out of some Aronhold heptad in $\mathbb{P}^3$ as in Proposition 4.1. Choose one construction like this, and let $L$ be the net of quadrics defined by the Aronhold heptad. The rational elliptic fibration $\kappa$ is given by the proper transforms of the members of the net $L$. Using Lemma 3.11 we see that the projectively dual curve of $C$ is the Hessian curve of the net $L$, which is a smooth quartic curve by Lemma 3.7.

Recall that to any (rational) fibration whose general fiber is an elliptic curve we can associate the $j$-function of its fibers, which is a rational function on the base of the fibration.

Remark 6.3. Let $V$ be a del Pezzo 3-fold of degree 1. The 3-fold $V$ can be defined in the weighted projective space $\mathbb{P}(1,1,1,2,3)$ with weighted homogeneous coordinates $s,t,u,v$, and $w$ by an equation of the form

$$w^2 = v^3 - h_4(s,t,u)v + h_6(s,t,u),$$

where $h_4$ and $h_6$ are homogeneous polynomials of degrees 4 and 6, respectively. Since the singularities of $V$ are isolated, the polynomial $4h_4(s,t,u)^3 - 27h_6(s,t,u)^2$ is not a zero polynomial. The rational elliptic fibration $\kappa$ is given by the projection to the coordinates $s$, $t$, and $u$. The corresponding $j$-function can be written as

$$j_V(s,t,u) = \frac{4h_4(s,t,u)^3}{4h_4(s,t,u)^3 - 27h_6(s,t,u)^2}$$

(see for instance [Dol12, §3.1.1]). In particular, the discriminant curve of $\kappa$ is given in $\mathbb{P}^2$ by the equation

$$4h_4(s,t,u)^3 - 27h_6(s,t,u)^2 = 0.$$

Recall from §3 that any (smooth) quartic curve $C$ in the projective plane $\mathbb{P}^2$ defines a $j$-function $j_C$ on the dual projective plane $\mathbb{P}^2$ that computes the $j$-invariant of the quartuple of intersection points of $C$ with the corresponding line. It is given by the formula (3.4).

Lemma 6.4. Let $V$ be a 28-nodal double Veronese cone, and let $C$ be the smooth plane quartic curve corresponding to $V$ via Lemma 6.2. Then $j_V(s,t,u) = j_C(s,t,u)$ for all $s,t,u$.

Proof. By Theorem 4.4 the 3-fold $V$ is constructed out of some net $L$ of quadrics in $\mathbb{P}^3$ as in Proposition 4.1. Let $P$ be a general point of $\mathbb{P}^2$. The point $P$ determines a one-dimensional linear subsystem $L_P$ of the net $L$. The fiber $E_P$ of the half-anticanonical elliptic fibration $\kappa$ over $P$ is the proper transform of the base locus of the pencil $L_P$. The base locus is given by the intersection of two general quadrics $Q_1$ and $Q_2$ in $L_P$. The pencil $L_P$ corresponds to the line $L$ in $\mathbb{P}^2$ dual to the point $P$. The singular quadrics in $L_P$ correspond to the four intersection points of the line $L$ and the Hessian curve $C$ of the net $L$. Lemma 3.9 implies that the curve $E_P$ is an elliptic curve isomorphic to the double cover of $L$ branched at the four intersection points of $L$ and $C$. This means that $j_V(P) = j_C(P)$.

We will need the following assertion on 28-nodal double Veronese cones and their half-anticanonical elliptic fibrations.

Lemma 6.5. Let $V$ be a 28-nodal double Veronese cone. Then $V$ is uniquely defined by the $j$-function $j_V$ of the fibers of the rational elliptic fibration $\kappa$.

Proof. Suppose that there exists another 28-nodal double Veronese cone $V'$ such that $j_V = j_{V'}$. The 3-folds $V$ and $V'$ can be defined in the weighted projective space $\mathbb{P}(1,1,1,2,3)$ with weighted homogeneous coordinates $s,t,u,v$, and $w$ by equations

$$(6.6) \quad w^2 = v^3 - h_4(s,t,u)v + h_6(s,t,u)$$

Recall from §3 that any (smooth) quartic curve $C$ in the projective plane $\mathbb{P}^2$ defines a $j$-function $j_C$ on the dual projective plane $\mathbb{P}^2$ that computes the $j$-invariant of the quartuple of intersection points of $C$ with the corresponding line. It is given by the formula (3.4).
and
\[(6.7)\]
\[w^2 = v^3 - k_4(s, t, u)v + k_6(s, t, u),\]
respectively, where \(h_d\) and \(k_d\) are homogeneous polynomials of degree \(d\). By Remark 6.3 the \(j\)-functions can be written as
\[j_V(s, t, u) = 1728 \frac{4h_4(s, t, u)^3}{4h_4(s, t, u)^3 - 27h_6(s, t, u)^2}\]
and
\[j_{V'}(s, t, u) = 1728 \frac{4k_4(s, t, u)^3}{4k_4(s, t, u)^3 - 27k_6(s, t, u)^2}.\]
Recall that neither \(h_4\) nor \(k_4\) is a zero polynomial by Lemmas 6.4 and 5.6. Since
\[j_V(s, t, u) = j_{V'}(s, t, u)\]
for all \(s, t, u\), we can easily conclude that
\[k_4(s, t, u) = ah_4(s, t, u), \quad k_6(s, t, u) = bh_6(s, t, u),\]
for some non-zero constants \(a\) and \(b\) with \(a^3 = b^2\). Thus equation (6.7) takes the form
\[w^2 = v^3 - ah_4(s, t, u)v + bh_6(s, t, u).\]
Put \(c = \frac{b}{a}\). Then \(c^2 = a\) and \(c^3 = b\). The automorphism of \(\mathbb{P}(1, 1, 1, 2, 3)\) defined by
\[\left[s : t : u : v : w\right] \mapsto \left[s : t : u : \frac{v}{c} : \frac{w}{c\sqrt{c}}\right]\]
brings it to the form (6.6), which means that \(V\) and \(V'\) are isomorphic. \(\Box\)

Now we are able to prove Theorem 1.3.

First proof of Theorem 1.3. By Lemma 6.2 a 28-nodal double Veronese cone uniquely determines a smooth plane quartic curve that is the projectively dual curve of the discriminant curve \(\hat{C}\) of the half-anticanonical rational elliptic fibration \(\kappa\).

Now let \(C\) be a smooth plane quartic curve. We then construct a 28-nodal double Veronese cone \(V\) from \(C\) as in (5) (see equation (5.10)). Using Remark 6.3 and Proposition 5.7 we see that the projectively dual curve of the discriminant curve of the rational elliptic fibration \(\kappa\) is isomorphic to \(C\).

It remains to show that if \(V'\) is a 28-nodal double Veronese cone such that the projectively dual curve of the discriminant curve of its half-anticanonical rational elliptic fibration is isomorphic to \(C\), then \(V'\) is isomorphic to \(V\). By Lemma 6.3 the \(j\)-functions of \(V\) and \(V'\) depend only on \(C\), so that
\[j_V(s, t, u) = j_{C}(s, t, u) = j_{V'}(s, t, u)\]
for all \(s, t, u\). According to Lemma 6.5 this means that \(V'\) is isomorphic to \(V\). \(\Box\)

We now move our attention to automorphism groups of 28-nodal double Veronese cones. Recall that if \(V\) is such a 3-fold, we denote by \(\tau\) the Galois involution of the double cover \(V \rightarrow \mathbb{P}(1, 1, 1, 2)\) given by the linear system \(|2H| = | - K_V|\). The automorphism \(\tau\) is contained in the center of the group \(\text{Aut}(V)\). It is easy to see that it preserves the fibers of the rational elliptic fibration \(\kappa\).

Proof of Theorem 1.4. Since the map \(\kappa: V \rightarrow \mathbb{P}^2\) is \(\text{Aut}(V)\)-equivariant, we have a group homomorphism
\[\tilde{\kappa}: \text{Aut}(V) \rightarrow \text{Aut}(\mathbb{P}^2).\]
Its kernel \(\mathcal{K} \subset \text{Aut}(V)\) acts on every fiber of \(\kappa\) preserving the unique base point \(O\) of \(|H|\). Let \(E\) be a general fiber of \(\kappa\). Then \(E\) is a general elliptic curve by Lemma 5.6 so that the stabilizer of the point \(O\) in \(\text{Aut}(E)\) is isomorphic to \(\mu_2\). Therefore, \(\mathcal{K}\) is a subgroup of \(\mu_2\). On the other hand, \(\mathcal{K}\) obviously contains the Galois involution \(\tau\) of the double cover given by the anticanonical linear system of \(V\). Thus we conclude that \(\mathcal{K} \cong \mu_2\).
Consider the action of the group $\Xi(\mathrm{Aut}(V))$ on the projective plane $\tilde{\mathbb{P}}^2$ which is the target of the map $\kappa$. By construction the action of $\Xi(\mathrm{Aut}(V))$ preserves the discriminant curve $\tilde{C}$ of the rational elliptic fibration $\kappa$, and hence its action on the projectively dual plane of the projective plane $\mathbb{P}^2$, which is $\mathbb{P}^2$, preserves the curve $C$ projectively dual to $\tilde{C}$. Therefore, we obtain a group homomorphism

$$\Xi: \mathrm{Aut}(V) \to \mathrm{Aut}(C)$$

whose kernel $\mathcal{K}$ is isomorphic to $\mu_2$. Note that at this moment we claim neither that $\Xi$ is surjective nor that $\mathcal{K}$ splits as a direct factor in $\mathrm{Aut}(V)$. However, we know that $\mathcal{K}$ is contained in the center of the group $\mathrm{Aut}(V)$.

Now let $G$ be the automorphism group of the smooth plane quartic $C$. Then $G$ is a finite group, and there is a natural action of $G$ on the plane $\mathbb{P}^2$ which is projectively dual to the plane $\mathbb{P}^2$ where the curve $C$ sits. By Remark 5.5 the latter action preserves the curves given by equations $g_4(s, t, u) = 0$ and $g_6(s, t, u) = 0$. This means that there exist group characters $\chi_4, \chi_6: G \to \mathbb{C}^*$ such that for any $\gamma \in G$ one has

$$g_4(\gamma(s, t, u)) = \chi_4(\gamma) \cdot g_4(s, t, u), \quad g_6(\gamma(s, t, u)) = \chi_6(\gamma) \cdot g_6(s, t, u).$$

On the other hand, the elements of $G$ preserve the equivalence class of the cross-ratio of a quadruple of intersection points of a line in $\mathbb{P}^2$ and the curve $C$; in other words, it preserves the $j$-function $j_C(s, t, u)$. By (5.4) this gives

$$\chi_4(\gamma)^3 = \chi_6(\gamma)^2$$

for every $\gamma \in G$. Set

$$\chi_2(\gamma) = \frac{\chi_6(\gamma)}{\chi_4(\gamma)}, \quad \gamma \in G.$$

Then $\chi_2$ is a character of $G$ such that $\chi_2(\gamma)^2 = \chi_4(\gamma)$ and $\chi_2(\gamma)^3 = \chi_6(\gamma)$. Since the image $\chi_2(G) \subset \mathbb{C}^*$ is a cyclic group, there is a well-defined character

$$\chi: G \to \mathbb{C}^*$$

such that $\chi(\gamma)^2 = \chi_2(\gamma)$ for all $\gamma \in G$. We have

$$\chi(\gamma)^4 = \chi_4(\gamma), \quad \chi(\gamma)^6 = \chi_6(\gamma).$$

Given an element $\gamma \in G$, we write

$$\gamma(s, t, u) = [s' : t' : u']$$

and define an automorphism of $\mathbb{P}(1, 1, 1, 2, 3)$ by

$$[s : t : u : v : w] \mapsto [s' : t' : u' : \chi(\gamma)^2 v : \chi(\gamma)^3 w].$$

Since the 3-fold $V$ is given by (5.10) in $\mathbb{P}(1, 1, 1, 2, 3)$, $G$ preserves the hypersurface $V$. This provides a group homomorphism

$$\Xi': \mathrm{Aut}(C) \to \mathrm{Aut}(V).$$

It is easy to see that $\Xi \circ \Xi' = \text{id}_{\mathrm{Aut}(C)}$. This implies that $\mathrm{Aut}(V) \cong \mathcal{K} \ltimes \mathrm{Aut}(C)$. Since $\mathcal{K} \cong \mu_2$ is contained in the center of $\mathrm{Aut}(V)$, we conclude that $\mathrm{Aut}(V) \cong \mathcal{K} \times \mathrm{Aut}(C)$. \hfill $\square$

**Corollary 6.8.** Let $V$ be a 28-nodal double Veronese cone, let $C$ be the smooth plane quartic curve corresponding to $V$ by Theorem 1.3, and let $S$ be the del Pezzo surface of degree 2 constructed as the double cover of $\mathbb{P}^2$ branched along $C$. Then

$$\mathrm{Aut}(V) \cong \mu_2 \times \mathrm{Aut}(C) \cong \mathrm{Aut}(S).$$
7. Theta characteristics

As we have seen in [4], Aronhold heptads, which are parts of regular Cayley octads, play a role in constructing 28-nodal double Veronese cones. On the other hand, neither an Aronhold heptad nor a regular Cayley octad is uniquely associated to a 28-nodal double Veronese cone. In what follows, correspondences between regular Cayley octads, smooth plane quartic curves, and 28-nodal double Veronese cones will be investigated in more detail, and the necessary additional data that is required to have natural one-to-one correspondences will be clarified.

So far we used Proposition 4.1 to construct 28-nodal double Veronese cones starting from Aronhold heptads. However, it turns out that the construction essentially depends only on the choice of the regular Cayley octad. This can be easily understood through Geiser type involutions.

Lemma 7.1. Let $P_1, \ldots, P_8$ be a regular Cayley octad in $\mathbb{P}^3$. Then for all $i = 1, \ldots, 8$ the 28-nodal double Veronese cones defined by the Aronhold heptads $\{P_1, \ldots, P_8\} \setminus \{P_i\}$ are isomorphic to each other.

Proof. For each $i = 1, \ldots, 8$, let $\hat{\mathbb{P}}^3_i$ be the blow up of $\mathbb{P}^3$ at the points $P_1, \ldots, P_8$ except the point $P_i$. Let $\tilde{\mathbb{P}}^3_{ij}$ be the weak Fano 3-fold obtained by blowing up $\mathbb{P}^3$ at the six points of $\{P_1, \ldots, P_8\} \setminus \{P_i, P_j\}$ and let $W_{ij}$ be its anticanonical model.

For $1 \leq k \neq l \leq 8$, denote by $L_{kl}$ the line passing through the points $P_k$ and $P_l$, and denote by $T_{kl}$ the twisted cubic passing through the six points of $\{P_1, \ldots, P_8\} \setminus \{P_k, P_l\}$. Let $\widehat{L}_{kl}$ and $\widehat{T}_{kl}$ be the proper transforms of these curves on $\tilde{\mathbb{P}}^3_{ij}$.

Proposition 4.6 implies that that $W_{ij}$ is the double cover of $\mathbb{P}^3$ branched over a quartic surface and that the map $\phi_{ij} : \hat{\mathbb{P}}^3_i \to W_{ij}$ given by the anticanonical linear system is a birational morphism that contracts exactly the 15 curves $\widehat{L}_{kl}$ for $k < l$ with $\{k, l\} \cap \{i, j\} = \emptyset$, and the curve $\widehat{T}_{ij}$. Denote by $\check{L}_{kl}$ and $\check{T}_{kl}$ the images on $W_{ij}$ of the curves $\widehat{L}_{kl}$ and $\widehat{T}_{kl}$ not contracted by $\phi_{ij}$, respectively.

Note that the points $\hat{P}_i$ and $\hat{P}_j$ on $W_{ij}$ corresponding to $P_i$ and $P_j$ are conjugate to each other with respect to the Galois involution $\varepsilon$ of the double cover.

The double cover $\zeta : W_{ij} \to \mathbb{P}^3$ is given by the half-anticanonical linear system, so that the pull-backs of planes under $\zeta$ should be the proper transforms of the quadrics in the original $\mathbb{P}^3$ passing through the six points of $\{P_1, \ldots, P_8\} \setminus \{P_i, P_j\}$. The images of the curves $\zeta(\check{T}_{kl})$ and $\zeta(\check{T}_{kj})$, where $k \notin \{i, j\}$, are lines in $\mathbb{P}^3$ (note however that the images $\zeta(\check{T}_{kl})$ for $\{k, l\} \cap \{i, j\} = \emptyset$ are conics). Therefore, by Lemma 3.3 for $k \notin \{i, j\}$ one has

$$
\varepsilon(\check{T}_{kl}) = \check{L}_{kl}, \quad \varepsilon(\check{L}_{kl}) = \check{T}_{kl},
$$

$$
\varepsilon(\check{T}_{kj}) = \check{L}_{kj}, \quad \varepsilon(\check{L}_{kj}) = \check{T}_{kj}.
$$

The involution $\varepsilon : W_{ij} \to W_{ij}$ gives rise to a birational map

$$
\hat{\varepsilon} : \hat{\mathbb{P}}^3_i \to \hat{\mathbb{P}}^3_j.
$$

Since $\varepsilon(\hat{P}_i) = \hat{P}_j$, we conclude that $\hat{\varepsilon}$ is actually an isomorphism.

Denote by $\hat{L}_{kl}^i$ and $\hat{T}_{kl}^i$ (respectively, $\check{L}_{kl}^i$ and $\check{T}_{kl}^i$) the proper transforms of the curves $L_{kl}$ and $T_{kl}$ on $\hat{\mathbb{P}}^3_i$ (respectively, $\check{\mathbb{P}}^3_i$). Then for $k \notin \{i, j\}$ one has

$$
\hat{\varepsilon}(\hat{T}_{kl}^i) = \hat{L}_{kl}^i, \quad \hat{\varepsilon}(\hat{L}_{kl}^i) = \hat{T}_{kl}^i,
$$

$$
\hat{\varepsilon}(\check{T}_{kl}^i) = \check{L}_{kj}^i, \quad \hat{\varepsilon}(\check{L}_{kj}^i) = \check{T}_{kj}^i.
$$

Also, we observe that for $\{k, l\} \cap \{i, j\} = \emptyset$

$$
\hat{\varepsilon}(\check{L}_{kl}) = \check{L}_{kl}, \quad \hat{\varepsilon}(\check{T}_{ij}) = \check{T}_{ij}.
$$
Therefore, the pluri-anticanonical maps \( \phi_i \) and \( \phi_j \) of \( \hat{\mathbb{P}}^3_i \) and \( \hat{\mathbb{P}}^3_j \) both factor through \( W_{ij} \), and the pluri-anticanonical models of \( \hat{\mathbb{P}}^3_i \) and \( \hat{\mathbb{P}}^3_j \), that are obtained by the construction described in Proposition 4.1, are both isomorphic to one and the same double Veronese cone \( V \).

This completes the proof of the statement. \( \square \)

Remark 7.2. A two-dimensional analog of Lemma 4.1 is the following simple observation. Let \( R_1, \ldots, R_9 \) be points in \( \mathbb{P}^2 \) in general position such that they are the intersection of two cubic curves. Then the del Pezzo surfaces of degree 1 obtained by blowing up the eight points of \( \{ R_1, \ldots, R_9 \} \setminus \{ R_i \} \) are isomorphic to each other for all \( 1 \leq i \leq 9 \).

Let \( \mathcal{N} \) be the set that consists of isomorphism classes of regular Cayley octads modulo projective transformations. Let \( \mathcal{T} \) be the set that consists of the pairs \((C, \theta)\), where \( C \) is a smooth plane quartic considered up to isomorphism, and \( \theta \) is an even theta characteristic on \( C \). A given regular Cayley octad defines a net \( \mathcal{L} \) of quadrics in \( \mathbb{P}^3 \). The net \( \mathcal{L} \) yields its Hessian quartic curve \( H(\mathcal{L}) \) in \( \mathbb{P}^2 \), which is smooth by Lemma 3.7. Meanwhile, the singular points of quadrics in the net \( \mathcal{L} \) sweep out a smooth curve of degree 6 in \( \mathbb{P}^3 \) (see [Bea77, Lemme 6.8] and [Bea77, Proposition 6.10]), which is called the Steinerian curve of the net and is denoted by \( S(\mathcal{L}) \). There is an even theta characteristic \( \theta(\mathcal{L}) \) such that the linear system \([ K_{H(\mathcal{L})} + \theta(\mathcal{L}) ]\) defines an isomorphism of \( H(\mathcal{L}) \) with \( S(\mathcal{L}) \) (see [Bea77, Proposition 6.10] and [Bea77, Lemme 6.12]). With such Hessian quartic curves and their even theta characteristics, we define the map

\[
\Theta : \mathcal{N} \rightarrow \mathcal{T}
\]

by assigning \( \Theta(\mathcal{L}) = (H(\mathcal{L}), \theta(\mathcal{L})) \).

Theorem 7.3. The map \( \Theta \) is bijective.

Proof. See [Bea77, Proposition 6.23]. \( \square \)

Suppose that the points \( P_1, \ldots, P_7 \) form an Aronhold heptad, and denote by \( P_8 \) the eighth base point of the net of quadrics \( \mathcal{L} \) defined by the Aronhold heptad. Choose a pair of points \( P_i, P_j \) in the regular Cayley octad \( P_1, \ldots, P_8 \). This pair yields a pencil in the net \( \mathcal{L} \) that consists of the quadrics containing the line passing through \( P_i \) and \( P_j \). The pencil contains exactly one or two singular quadrics (see [Bea77, Lemme 6.6(i)])]. Furthermore, the pencil defines a line in the projective plane where the Hessian quartic curve \( H(\mathcal{L}) \) sits, and this line is bitangent to the Hessian quartic curve (see [Dol12, Theorem 6.3.5]). Such a bitangent line defines an odd theta characteristic of \( H(\mathcal{L}) \). It will be denoted by \( \theta_{ij}(\mathcal{L}) \). It is obvious that \( \theta_{ij}(\mathcal{L}) = \theta_{kl}(\mathcal{L}) \) if and only if \( \{i, j\} = \{k, l\} \). In particular, every odd theta characteristic on \( H(\mathcal{L}) \) can be represented by \( \theta_{ij}(\mathcal{L}) \) for some \( i \) and \( j \).

For each choice of four distinct indices \( i, j, k, l \) in \( \{1, \ldots, 8\} \), set

\[
\theta_{i,jkl} = \theta_{ij}(\mathcal{L}) + \theta_{ik}(\mathcal{L}) + \theta_{il}(\mathcal{L}) - K_{H(\mathcal{L})}.
\]

Before we proceed, notice that

\[
\theta_{ij}(\mathcal{L}) + \theta_{ik}(\mathcal{L}) + \theta_{jk}(\mathcal{L}) = K_{H(\mathcal{L})} + \theta(\mathcal{L})
\]
for each choice of three distinct indices \( i, j, k \) in \( \{1, \ldots, 8\} \) since the left hand side is the section of the Steinerian curve \( S(\mathcal{L}) \) by the plane containing the points \( P_1, P_j, \) and \( P_k \) in \( \mathbb{P}^3 \).

**Lemma 7.6.** Let \( r \) be a fixed index in \( \{1, \ldots, 8\} \).

- The theta characteristic \( \theta_{r,ijk} \) is even for three distinct indices \( i, j, k \) in \( \{1, \ldots, 8\} \setminus \{r\} \).
- Every even theta characteristic on \( H(\mathcal{L}) \) except \( \theta(\mathcal{L}) \) can be represented as \( \theta_{r,ijk} \) for some choice of three distinct indices \( i, j, k \) in \( \{1, \ldots, 8\} \setminus \{r\} \).
- One has

\[
\theta(\mathcal{L}) = -3K_H(\mathcal{L}) + \sum_{i \neq r} \theta_{r1}(\mathcal{L}).
\]

**Proof.** For the first statement, see \[\text{Doi12, Theorem 6.3.6}\] or \[\text{DOSS8 Proposition IX.4}\].

Since there are exactly 35 even theta characteristics excluding \( \theta(\mathcal{L}) \), in order to prove the second statement, it is enough to verify that \( \theta_{r,ijk1} \neq \theta_{r,ijk2} \) if \( \{i_1, j_1, k_1\} \neq \{i_2, j_2, k_2\} \). Suppose that \( \theta_{r,ijk_1} = \theta_{r,ijk_2} \). For convenience, assume that \( r = 8 \). Then

\[\theta_{8i_1}(\mathcal{L}) + \theta_{8j_1}(\mathcal{L}) + \theta_{8k_1}(\mathcal{L}) + \theta_{8i_2}(\mathcal{L}) + \theta_{8j_2}(\mathcal{L}) + \theta_{8k_2}(\mathcal{L}) - 3K_H(\mathcal{L}) = \theta_{r,i_1j_1k_1} + \theta_{r,i_2j_2k_2} - K_H(\mathcal{L}) = 0.\]

If \( \{i_1, j_1, k_1\} \cap \{i_2, j_2, k_2\} = \emptyset \), then the above equality and (7.5) imply

\[\theta_{ij}(\mathcal{L}) + \theta_{ij}(\mathcal{L}) + \theta_{ij}(\mathcal{L}) = 3\theta(\mathcal{L}) = K_H(\mathcal{L}) + \theta(\mathcal{L}).\]

This means that the six points \( P_{i_1}, P_{j_1}, P_{j_1}, P_{j_2}, P_{k_1}, P_{k_2} \) lie on a single plane, which is impossible by Lemma 3.2. If \( \{i_1, j_1, k_1\} \cap \{i_2, j_2, k_2\} \neq \emptyset \), then we may assume that \( i_1 = i_2 \). Then

\[\theta_{8j_1}(\mathcal{L}) + \theta_{8k_1}(\mathcal{L}) = \theta_{8j_2}(\mathcal{L}) + \theta_{8k_2}(\mathcal{L}).\]

This together with (7.5) implies

\[\theta_{j_1k_1}(\mathcal{L}) = \theta_{j_2k_2}(\mathcal{L}),\]

and hence \( \{i_1, j_1, k_1\} = \{i_2, j_2, k_2\} \).

Now let us prove the third statement. Suppose that the right hand side of (7.7) is an odd theta characteristic \( \theta_{mn}(\mathcal{L}) \). Then \( m, n \neq r \); otherwise \( \theta_{r,ijk} \) would yield the same even theta characteristic for two different choices of three distinct indices \( i, j, k \), which is not the case by the second statement. For convenience, we may assume that \( r = 8, m = 2, \) and \( n = 1 \). Then our assumption reads

\[\theta_{21}(\mathcal{L}) = -3K_{H(\mathcal{L})} + \sum_{i=1}^{7} \theta_{8i}(\mathcal{L}).\]

By (7.5) this yields

\[
-K_{H(\mathcal{L})} + \sum_{i=3}^{7} \theta_{8i}(\mathcal{L}) = \theta_{21}(\mathcal{L}) + \theta_{81}(\mathcal{L}) + \theta_{82}(\mathcal{L}) = K_{H(\mathcal{L})} + \theta(\mathcal{L}).
\]

Note that

\[K_{H(\mathcal{L})} + \theta(\mathcal{L}) = \theta_{43}(\mathcal{L}) + \theta_{83}(\mathcal{L}) + \theta_{84}(\mathcal{L})\]

by (7.5). Using this, we deduce from (7.8) that

\[-K_{H(\mathcal{L})} + \sum_{i=5}^{7} \theta_{8i}(\mathcal{L}) = \theta_{43}(\mathcal{L}).\]

This contradicts the first statement. Therefore, the right hand side of (7.7) is an even theta characteristic.

We now suppose that the right hand side of (7.7) is not \( \theta(\mathcal{L}) \). Then, due to the second statement, we may assume that \( r = 8 \) and

\[-3K_{H(\mathcal{L})} + \sum_{i=1}^{7} \theta_{8i}(\mathcal{L}) = \theta_{81}(\mathcal{L}) + \theta_{82}(\mathcal{L}) + \theta_{83}(\mathcal{L}) - K_{H(\mathcal{L})}.\]
However, this implies an absurd identity $\theta_{8,456} = \theta_{87}(L)$. Consequently, the right hand side of (7.7) must be $\theta(L)$.

Let $L_{\theta_{i,jkl}}$ be the net of quadrics corresponding to the plane quartic $H(L)$ and the even theta characteristic $\theta_{i,jkl}$ via the bijection from Theorem 7.3 and let $S_{\theta_{i,jkl}}$ be its Steinerian curve. It turns out that these curves (and also regular Cayley octads and nets of quadrics) are related by standard Cremona transformations of $\mathbb{P}^3$.

**Proposition 7.9.** Up to projective transformation, the curve $S_{\theta_{i,jkl}}$ is obtained from $S(L)$ by the standard Cremona transformation centered at the points $P_i$, $P_j$, $P_k$, $P_l$, and also by the standard Cremona transformation centered at the complementary set of points $P_m$, $P_n$, $P_o$, $P_t$.

*Proof.* See [DO88, Proposition IX.4].

**Remark 7.10.** By Lemma 7.6 the 35 even theta characteristics on $H(L)$ other than $\theta(L)$ are all of the form (7.4) for a fixed index $i$ (one can take for instance $i = 8$). This means that the even theta characteristics obtained as in Proposition 7.9 by the 35 Cremona transformations associated to choices of four points out of the seven points $P_1$, $P_2$, $P_3$ (alternatively, by the 35 Cremona transformations associated to the point $P_8$ and choices of three points out of $P_1$, $P_2$, $P_3$) are pairwise different.

Using Corollary 7.10 we deduce the following.

**Corollary 7.11.** Up to projective transformation, the net of quadrics $L_{\theta_{i,jkl}}$ consists of the proper transforms of the quadrics from the net $L$ with respect to the standard Cremona transformation $\varsigma$ centered at the points $P_i$, $P_j$, $P_k$, $P_l$ (or with respect to the standard Cremona transformation centered at the complementary set of points $P_m$, $P_n$, $P_o$, $P_t$). Furthermore, the corresponding regular Cayley octad $P_1', P_2', P_3'$ can be constructed as follows: the points $P_1'$, $P_2'$, $P_3'$ are the images of the divisors $\varsigma(P_i)$, $\varsigma(P_j)$, $\varsigma(P_k)$, respectively, and $P_r'$ is obtained from $P_r$ (alternatively, by the 35 Cremona transformations associated to the point $P_8$) for $r = m, n, s, t$.

*Proof.* After a suitable projective transformation we may assume that

$$P_i = [1 : 0 : 0 : 0], \quad P_j = [0 : 1 : 0 : 0], \quad P_k = [0 : 0 : 1 : 0], \quad P_l = [0 : 0 : 0 : 1].$$

Then the standard Cremona transformation $\varsigma$ is the selfmap of $\mathbb{P}^3$ defined by

$$\varsigma(x_0, x_1, x_2, x_3) = \left[ \frac{1}{x_0} : \frac{1}{x_1} : \frac{1}{x_2} : \frac{1}{x_3} \right].$$

Every quadric surface in $L$ is defined by a quadric homogeneous polynomial of the form

$$\sum_{\{\alpha, \beta \neq \delta\}} a_{\alpha \beta} x_\alpha x_\beta = 0,$$

where $a_{\alpha \beta} = a_{\beta \alpha}$. Its proper transform by $\varsigma$ is defined by the quadric homogeneous polynomial

$$\sum_{\{\alpha, \beta, \gamma, \delta = 0,1,2,3\}} a_{\alpha \beta} x_\gamma x_\delta = 0.$$

The four coordinate points and the four points $\varsigma(P_m)$, $\varsigma(P_n)$, $\varsigma(P_o)$, $\varsigma(P_t)$ are the eight intersection points of three quadrics. Lemma 8.1 then implies that the net $L'$ of quadric surfaces passing through these eight points is exactly the net of the proper transforms of the quadric surfaces in $L$. Observe that the symmetric matrix corresponding to the former quadric surface and the one corresponding to the latter have the same determinant. It then follows from Lemma 8.1 that the four coordinate points and the four points $\varsigma(P_m)$, $\varsigma(P_n)$, $\varsigma(P_o)$, $\varsigma(P_t)$ form a regular Cayley octad. It also immediately follows from our observation that the Steinerian curve $S(L')$ is the proper transform of the Steinerian curve $S(L)$ with respect to $\varsigma$. Hence by Proposition 7.9 we have

$$S(L') = S_{\theta_{i,jkl}}.$$
up to projective transformation. By Theorem 7.3 this implies that

\[ \mathcal{L}' = \mathcal{L}_{\theta_i,jkl}, \]

and the assertion follows. \(\square\)

For a given smooth plane quartic curve \(C\) equipped with an even theta characteristic \(\theta\), its associated net \(\mathcal{L}\) of quadrics determines a regular Cayley octad \(P_1, \ldots, P_8\) in \(\mathbb{P}^3\), which in turn allows us to construct a unique 28-nodal double Veronese cone \(V_{C, \theta}\) (see Lemma 7.1). Let \(\theta'\) be another even theta characteristic on \(C\), and let \(V_{C, \theta'}\) be the corresponding 28-nodal double Veronese cone.

**Lemma 7.12.** The 3-folds \(V_{C, \theta}\) and \(V_{C, \theta'}\) are isomorphic.

**Proof.** By Remark 7.10 there are indices \(1 \leq i < j < k \leq 7\) such that

\[ \theta' = \theta_{8i}(\mathcal{L}) + \theta_{8j}(\mathcal{L}) + \theta_{8k}(\mathcal{L}) - K_C. \]

For convenience, let us say \(i = 5, j = 6, k = 7\). Corollary 7.11 tells us that the net of quadrics \(\mathcal{L}'\) associated to \((C, \theta')\) via Theorem 7.3 can be obtained by applying the standard Cremona transformation \(\zeta\) centered at the points \(P_1, P_2, P_3, P_4\) to the original net \(\mathcal{L}\), up to projective equivalence. Furthermore, the net \(\mathcal{L}'\) is defined by the regular Cayley octad \(P'_1, \ldots, P'_8\), where \(P'_1, \ldots, P'_4\) are the images of the divisors contracted by \(\zeta\), and set \(P'_i = \zeta(P_i)\) for \(i = 5, \ldots, 8\). The 3-folds \(V_{C, \theta}\) and \(V_{C, \theta'}\) are constructed from the Aronhold heptads \(P_1, \ldots, P_7\) and \(P'_1, \ldots, P'_7\), respectively.

Let \(\mathbb{P}^3\) be the blow up of \(\mathbb{P}^3\) at \(P_1, \ldots, P_7\). Denote by \(F_i\) the exceptional divisor on \(\mathbb{P}^3\) over the point \(P_i\). Let \(L_{ij}\) be the line in \(\mathbb{P}^3\) passing through the points \(P_i\) and \(P_j\) with \(i < j\), and let \(\tilde{L}_{ij}\) be its proper transform on \(\mathbb{P}^3\). Flopping the six curves \(\tilde{L}_{ij}\) with \(1 \leq i < j \leq 4\), we obtain a birational map \(\xi\) from \(\mathbb{P}^3\) to another weak Fano 3-fold \(\mathbb{P}^3^+\). Thus, we obtain the following diagram:

\[
\begin{array}{ccc}
\mathbb{P}^3 & \xrightarrow{\xi} & \mathbb{P}^3^+ \\
V & \downarrow \nu & \\
\uparrow \nu' & \\
\end{array}
\]

Here \(\nu\) and \(\nu'\) are contractions of the flopping curves of \(\xi\) and \(\xi^{-1}\), respectively.

Keeping in mind the decomposition of the standard Cremona transformation into blow ups and blow downs, we see that \(\mathbb{P}^3^+\) can be represented as the blow up \(\pi^+ : \mathbb{P}^3^+ \to \mathbb{P}^3\) at the points \(P'_1, \ldots, P'_7\). More precisely, let \(\Pi_i, 1 \leq i \leq 4\), be the plane passing through the three points among \(P_1, \ldots, P_4\) except \(P_i\). The proper transforms of the four planes \(\Pi_i\) in \(\mathbb{P}^3^+\) are four disjoint surfaces \(\Pi_i^+\) isomorphic to \(\mathbb{P}^2\). Let \(F_i^+, 5 \leq i \leq 7\), be the proper transforms in \(\mathbb{P}^3^+\) of the surfaces \(F_i\). Then the surfaces \(\Pi_1^+, \Pi_2^+, \Pi_3^+, \Pi_4^+, F_5^+, F_6^+, \text{ and } F_7^+\) are contracted to the seven points \(P'_1, \ldots, P'_7\) on \(\mathbb{P}^3\), respectively.

By Proposition 4.11 the 3-folds \(V_{C, \theta}\) and \(V_{C, \theta'}\) are the images of the pluri-anticanonical morphisms \(\phi\) and \(\phi^+\) of \(\mathbb{P}^3\) and \(\mathbb{P}^3^+\), respectively. Since \(\xi\) is a flop, both \(\phi\) and \(\phi^+\) factor through \(V\), so that both \(V_{C, \theta}\) and \(V_{C, \theta'}\) are obtained by contracting one and the same curves on \(V\). Thus, \(V_{C, \theta}\) and \(V_{C, \theta'}\)
are isomorphic to one and the same double Veronese cone $V$.

This completes the proof of the lemma.

Lemmas 7.1 and 7.12 give the following

**Corollary 7.13.** Let $C$ be a smooth plane quartic curve. Then for any choice of an even theta characteristic $\theta$ on $C$, and for any choice of an Aronhold heptad in the regular Cayley octad corresponding to $\theta$, the 28-nodal double Veronese cones constructed from these Aronhold heptads as in Proposition 4.1 are isomorphic to each other.

Corollary 7.13 allows us to put together the following proof.

**Second proof of Theorem 7.3.** Given a 28-nodal double Veronese cone, we associate to it a smooth plane quartic curve as in Lemma 6.2

Let $C$ be a smooth plane quartic curve. Choose an even theta characteristic on $C$. By Theorem 7.3 this provides us a regular Cayley octad. Choose an Aronhold heptad from this regular Cayley octad, and construct a 28-nodal double Veronese cone as in Proposition 4.1. By Corollary 7.13 the result does not depend on the choice of the even theta characteristic and the Aronhold heptad, and by Theorem 4.4 every 28-nodal double Veronese cone can be obtained in this way. Using Lemma 6.2 once again, we see that the above two constructions are mutually inverse.

Recall from [DO88, § IX.2] that a (unordered) set of seven distinct odd theta characteristics $\theta_1, \ldots, \theta_7$ on a smooth plane quartic curve $C$ is called an *Aronhold system* if they satisfy the condition that $\theta_i + \theta_j + \theta_k - K_C$ is an even theta characteristic for each choice of three distinct indices $i, j, k$. This is equivalent to the requirement that the six points of any three of $\theta_1, \ldots, \theta_7$ are not contained in a conic because

$$|2K_C - \theta_i - \theta_j - \theta_k| = |\theta_i + \theta_j + \theta_k - K_C|.$$ 

A given smooth quartic has exactly 288 Aronhold systems (see [DO88, Proposition IX.3]).

It follows from Lemma 7.6 that if $P_1, \ldots, P_8$ is a regular Cayley octad, and $\mathcal{L}$ is the corresponding net of quadrics in $\mathbb{P}^3$, then for every fixed index $r \in \{1, \ldots, 8\}$ the seven odd theta characteristics $\theta_{ri}(\mathcal{L})$, $i \neq r$, form an Aronhold system. It turns out that all Aronhold systems arise in this way.

**Lemma 7.14** (cf. [Dol12, Proposition 6.3.11]). Let $C$ be a smooth plane quartic, and let $\Xi$ be an Aronhold system on $C$. Then there exist a unique even theta characteristic $\theta$ on $C$ and a unique point $P_8$ in the regular Cayley octad $P_1, \ldots, P_8$ corresponding to $(C, \theta)$ via Theorem 7.3 such that

$$\Xi = \{\theta_{si}(\mathcal{L}) \mid 1 \leq i \leq 7\},$$

where $\mathcal{L}$ is the net of quadrics defined by the regular Cayley octad $P_1, \ldots, P_8$. 28
Proof. For a given even theta characteristic $\theta$ on $C$, we obtain a regular Cayley octad $P_1, \ldots, P_8$ in $\mathbb{P}^3$ from Theorem 7.3. This gives us eight distinct Aronhold systems $\Xi_1, \ldots, \Xi_8$ on $C$ as in (7.15). By Lemma 7.6 one has

$$\theta = -3K_C + \sum_{\vartheta \in \Xi_r} \vartheta$$

for every $r \in \{1, \ldots, 8\}$. Hence none of the Aronhold systems $\Xi_r$ can coincide with an Aronhold system constructed in the same way starting from any other even theta characteristic $\theta' \neq \theta$ on $C$. Since there are exactly 288 Aronhold systems and exactly 36 even theta characteristics on $C$, the above construction exhausts all the Aronhold systems on $C$, and the assertion follows. $\square$

Lemmas 7.6 and 7.14 imply the following.

Corollary 7.16. Let $C$ be a smooth plane quartic, and let $\Xi$ be an Aronhold system on $C$. Then

$$(7.17) \quad \theta = -3K_C + \sum_{\vartheta \in \Xi} \vartheta$$

is an even theta characteristic on $C$. Moreover, for every even theta characteristic $\theta$ on $C$ there exist exactly eight Aronhold systems such that $\theta$ is obtained from them as in (7.17), and each of these eight Aronhold systems is in turn obtained from $\theta$ as in Lemma 7.14.

To proceed we need to define a certain equivalence relation on the set of Aronhold systems. Let $T_a$ be the set that consists of the pairs $(C, \Xi)$, where $C$ is a smooth quartic curve considered up to isomorphism, and $\Xi$ is an Aronhold system on $C$. Two members $(C_1, \Xi_1)$ and $(C_2, \Xi_2)$ in $T_a$ are considered to be equivalent if

- $C_1 = C_2$;
- one has $\sum_{\vartheta \in \Xi_1} \vartheta = \sum_{\vartheta \in \Xi_2} \vartheta$;
- there is an automorphism $\sigma: C_1 \to C_2$ such that $\sigma^*(\Xi_2) = \Xi_1$.

In other words, the equivalence comes from the action of stabilizers of the even theta characteristic attached to $(C, \Xi)$ by (7.17) in the automorphism group of $C$. Let $T_A$ be the set of the equivalence classes of members in $T_a$. Let $A$ be the set of Aronhold heptads in $\mathbb{P}^3$ up to projective transformations. Define a map

$$\Delta: A \to T_A$$

by assigning to a given Aronhold heptad the Hessian curve of the corresponding net of quadrics together with the Aronhold system constructed as in (7.15).

Theorem 7.18. The map $\Delta$ is bijective.

Proof. It is enough to show that for a given smooth plane quartic curve $C$ the map $\Delta$ induces one-to-one correspondence between members of $A$ with the Hessian curve $C$ and members of $T_A$ with the first component $C$.

It immediately follows from Lemma 7.14 that the map $\Delta$ is surjective.

Suppose that $\Delta(X) = \Delta(Y)$ for Aronhold heptads $X$ and $Y$. First of all, the Hessian curves of the nets of quadrics determined by $X$ and $Y$, respectively, are one and the same smooth quartic curve $C$. Let $\Xi_X$ and $\Xi_Y$ be the Aronhold systems determined by $X$ and $Y$, respectively. Then

$$-3K_C + \sum_{\vartheta \in \Xi_X} \vartheta = -3K_C + \sum_{\vartheta \in \Xi_Y} \vartheta$$

is one and the same even theta characteristic $\theta$ on $C$. Furthermore, since $\Delta(X) = \Delta(Y)$, there is an automorphism $\sigma$ of $C$ such that $\Xi_X = \sigma^*(\Xi_Y)$. Then the automorphism $\sigma$ preserves the linear system $|K_C + \theta|$ that is the linear system of hyperplane sections of the Steinerian curve of the net of quadrics $\mathcal{L}$ in $\mathbb{P}^3$ corresponding to $(C, \theta)$ via Theorem 7.3. This means that the automorphism $\sigma$
considered as an automorphism of the Steinerian curve is induced from a projective transformation of $\mathbb{P}^3$ preserving the regular Cayley octad defined by $\mathcal{L}$. Thus, we conclude that $X = Y$ in $\mathcal{A}$. □

**Corollary 7.19.** Let $V$ be a 28-nodal double Veronese cone, and let $C$ be the smooth plane quartic curve corresponding to $V$ via Theorem 1.3. Then there exists a natural one-to-one correspondence between the set of the diagrams (1.1) considered up to projective transformations of $\mathbb{P}^3$ and the set of members in $\mathcal{T}_A$ with the first component in the pair isomorphic to $C$.

**Proof.** This immediately follows from Theorem 7.18, because by Corollary 7.13 there is an obvious one-to-one correspondence between the set of the diagrams (1.1) considered up to projective transformations of $\mathbb{P}^3$ and the set of members in $\mathcal{A}$ with the Hessian curve $C$. □

**Corollary 7.20.** For a general smooth plane quartic curve $C$, there are exactly 288 diagrams (1.1) associated to $C$, up to projective transformations of $\mathbb{P}^3$.

If the smooth plane quartic curve $C$ is not general, the number of diagrams (1.1) associated to $C$ up to projective transformations of $\mathbb{P}^3$ may be smaller than 288. Note however that this number is always at least 36.

**Example 7.21.** Let $C$ be the Klein quartic curve given in $\mathbb{P}^2$ by the equation

$$x^3 y + y^3 z + z^3 x = 0.$$ 

Then $\text{Aut}(C) \cong \text{PSL}_2(\mathbb{F}_7)$. There exists a unique $\text{Aut}(C)$-invariant even theta characteristic $\theta_0$ on $C$ (see [Bur83, Example 2] or [Dol99, Example 2.8]). The remaining 35 even theta characteristics split into three $\text{Aut}(C)$-orbits of lengths 7, 7, and 21, respectively (see [DK93, (8.3)]). Furthermore, according to [JvOS94, Theorem 10.1] the set of 288 Aronhold systems on $C$ splits into four $\text{Aut}(C)$-orbits of lengths 8, 56, 56, and 168, respectively. This means that the stabilizer of every even theta characteristic $\theta$ in $\text{Aut}(C)$ acts transitively on the set of eight Aronhold systems corresponding to $\theta$ via (7.17).

Now let $V$ be the 28-nodal double Veronese cone corresponding to $C$ via Theorem 1.3. Corollary 7.19 tells us that $V$ admits exactly 36 diagrams (1.1) up to projective transformations of $\mathbb{P}^3$. One of them corresponds to the $\text{Aut}(C)$-invariant theta characteristic $\theta_0$. The group $\text{Aut}(C)$ acts on the corresponding three-dimensional projective space preserving the regular Cayley octad. Note however that since the regular Cayley octad in $\mathbb{P}^3$ is a single $\text{Aut}(C)$-orbit (see for instance [CS12, Lemma 3.2]), this diagram is not equivariant with respect to the whole group $\text{Aut}(C)$. It is equivariant with respect to the subgroup $\mu_7 \times \mu_3 \subset \text{Aut}(C)$.

There is another natural way to recover the smooth plane quartic $C$ corresponding to the 28-nodal double Veronese cone $V$.

Let $P_1, \ldots, P_7$ be seven points in $\mathbb{P}^3$ that form an Aronhold heptad. Let $P_8$ be the eighth base point of the net $\mathcal{L}(P_1, \ldots, P_7)$. Let $\rho: \mathbb{P}^3 \rightarrow \mathbb{P}^2$ be the linear projection centered at $P_8$.

**Lemma 7.22.** No three of the seven points $\rho(P_1), \ldots, \rho(P_7)$ are collinear (so that in particular no two of them coincide), and no six points among them are contained in a conic.

**Proof.** If three points, say $\rho(P_1)$, $\rho(P_2)$, and $\rho(P_3)$, lie on a line, then the four points $P_1, P_2, P_3$, and $P_8$ lie on a plane. This implies that there is an element in $\mathcal{L}(P_1, \ldots, P_7)$ that contains the plane. Otherwise the restriction of the net $\mathcal{L}(P_1, \ldots, P_7)$ to the plane would define a net of conics passing through the four points $P_1, P_2, P_3$, and $P_8$.

We now suppose that six points, say $\rho(P_1), \ldots, \rho(P_6)$, lie on a conic. Then there is a quadric surface in $\mathbb{P}^3$ passing through the six points $P_1, \ldots, P_6$ together with $P_8$. It follows from Lemma 5.1 that the quadric surface should pass through the point $P_7$. If the base point $P_8$ of the net $\mathcal{L}(P_1, \ldots, P_7)$ is a singular point of a member of the net, then the base locus of the net $\mathcal{L}(P_1, \ldots, P_7)$ could not consists of eight distinct points. □
Remark 7.23. The heptad \( \rho(P_1), \ldots, \rho(P_7) \) is the Gale transform of the heptad \( P_1, \ldots, P_7 \) (see \[EP00\]), and in particular the examples following \[EP00\] Corollary 3.2]. Thus, the points \( \rho(P_1), \ldots, \rho(P_7) \) uniquely define the Aronhold heptad \( P_1, \ldots, P_7 \) and the regular Cayley octad \( P_1, \ldots, P_8 \) up to projective transformations of \( \mathbb{P}^3 \).

Now let \( \alpha : S \to \mathbb{P}^2 \) be the blow up of \( \mathbb{P}^2 \) at the seven points \( \rho(P_1), \ldots, \rho(P_7) \). By Lemma 7.22 the surface \( S \) is a smooth del Pezzo surface of degree 2, so that its anticanonical linear system yields the double cover \( \varphi : S \to \mathbb{P}^2 \) branched along some smooth plane quartic curve \( C \). The quartic curve \( C \) coincides with the Hessian curve of the net of quadrics \( L(P_1, \ldots, P_7) \) (see \[DO88\] Proposition IX.2] or \[DOSS88\] Proposition IX.2]). The above maps are diagrammed as follows:

\[
\begin{array}{ccc}
V & \xleftarrow{\phi} & \mathbb{P}^3 \\
\downarrow{\kappa} & & \downarrow{\pi} \\
\mathbb{P}^2 & \xrightarrow{\phi} & \mathbb{P}^2
\end{array}
\]

Here \( \phi \) is a small resolution of all singular points of the 3-fold \( V \), the morphism \( \pi \) is the blow up of \( \mathbb{P}^3 \) at the seven distinct points \( P_1, \ldots, P_7 \), and the rational map \( \kappa \) is given by the half-anticanonical linear system of \( V \).

Remark 7.25. The image of the exceptional curve of \( \alpha \) over the point \( \rho(P_i) \) by the double cover morphism \( \varphi \) is the bitangent line of \( C \) corresponding to the odd theta characteristic \( \theta_{\bar{\kappa}}(L) \) (see \[DOSS88\] Proposition IX.2]). These seven odd theta characteristic form an Aronhold system. Moreover, this Aronhold system is the same as the one given by \((7.15)\).

Remark 7.26. Following the diagram \((7.24)\), one may easily figure out the last statement in Lemma 8.9. Indeed, a fiber of the rational map \( \kappa \) is given by the base locus of a pencil contained in the net \( L(P_1, \ldots, P_7) \). In case of a smooth fiber, the fiber is the proper transform of a smooth intersection \( E \) of two quadrics in the net. The intersection \( E \) is a curve of degree 4 passing through eight points \( P_1, \ldots, P_8 \) which are the base points of the net. Thus the projection \( \rho \) sends \( E \) to a cubic curve passing through the seven points \( \rho(P_1), \ldots, \rho(P_7) \). The proper transform of this cubic curve on the del Pezzo surface \( S \) is a smooth member of the anticanonical linear system of \( S \). Since the double cover \( \varphi \) is given by \( | - K_S | \), the latter proper transform is the pull-back of a line on \( \mathbb{P}^2 \) by \( \varphi \). It is the double cover of the line branched at the distinct four points at which the line and the quartic curve \( C \) intersect. The point of the dual projective plane corresponding to this line is exactly the point over which the original fiber lies.

8. \( \mathfrak{S}_4 \)-symmetric 28-nodal double Veronese cones

In this section we study the \( \mathfrak{S}_4 \)-equivariant birational geometry of double Veronese cones introduced in Example 1.3. We consider the automorphisms of \( \mathbb{P}(1,1,1,2,3) \)

\[
\tau : [s : t : u : v : w] \mapsto [s : t : u : v : -w],
\sigma_1 : [s : t : u : v : w] \mapsto [-s : -t : u : v : w],
\sigma_2 : [s : t : u : v : w] \mapsto [u : s : t : v : w],
\sigma_3 : [s : t : u : v : w] \mapsto [t : s : u : v : -w].
\]

Since they keep \( V \) invariant, they may be regarded as automorphisms of \( V \). Then the involution \( \tau \) is the Galois involution of the double cover of the Veronese cone. Moreover, by Theorem 1.4, we have

\[
\text{Aut}(V) \cong \mu_2 \times \text{Aut}(C),
\]

where the subgroup \( \mu_2 \) is generated by \( \tau \).
Let $\mathfrak{G}$ be the subgroup in $\text{Aut}(V)$ that is generated by $\sigma_1$, $\sigma_2$, and $\tau_3$, and let $\mathfrak{G}'$ be the subgroup in $\text{Aut}(V)$ generated by $\sigma_1$, $\sigma_2$, and $\tau \circ \tau_3$. Then $\mathfrak{G} \cong \mathfrak{G}' \cong \mathfrak{G}_4$, and both of them are projected isomorphically to the same subgroup in $\text{Aut}(C)$. Meanwhile, the subgroups $\mathfrak{G}$ and $\mathfrak{G}'$ are not conjugate in $\text{Aut}(V)$.

To facilitate the computations, introduce an auxiliary variable

\begin{equation}
\bar{v} = v - \mu(s^2 + t^2 + u^2),
\end{equation}

where $\mu = \frac{2\lambda}{3}$. The defining equation of the 3-fold $V$ may then be rewritten as

\begin{equation}
w^2 = \bar{v} \left( \bar{v}^2 + 3\mu \bar{v}(s^2 + t^2 + u^2) + 3\mu^2(s^2 + t^2 + u^2)^2 - g_4(s, t, u) \right) + \mu^3(s^2 + t^2 + u^2)^3 - \mu(s^2 + t^2 + u^2)g_4(s, t, u) + g_6(s, t, u).
\end{equation}

One has

\[ \mu^3(s^2 + t^2 + u^2)^3 - \mu(s^2 + t^2 + u^2)g_4(s, t, u) + g_6(s, t, u) = 4(\lambda - 2)^2(\lambda + 1)s^2 t^2 u^2. \]

Set $\gamma = 2(\lambda - 2)\sqrt{\lambda + 1}$. We see from (8.2) that the 3-fold $V$ contains the surfaces $\Pi_{\pm}$ given by equations

\begin{equation}
\bar{v} = w \mp \gamma stu = 0,
\end{equation}

that is, by equations

\begin{equation}
\begin{cases}
  v = \mu(s^2 + t^2 + u^2), \\
  w = \pm \gamma stu.
\end{cases}
\end{equation}

Note also that both $\Pi_{\pm}$ and $\Pi_{\mp}$ are $\mathfrak{G}'$-invariant, and both of them are not $\mathbb{Q}$-Cartier divisors. In particular, we see that $\text{rk} \, \text{Cl}(V)^{\mathfrak{G}'} \neq 1$.

Let us introduce a new coordinate

\[ r = \frac{w - \gamma stu}{\bar{v}}. \]

On the 3-fold $V$, one has

\[ r = \frac{\bar{v}^2 + 3\mu \bar{v}(s^2 + t^2 + u^2) + 3\mu^2(s^2 + t^2 + u^2)^2 - g_4(s, t, u)}{w + \gamma stu}. \]

This gives us a birational map of $V$ to the complete intersection in $\mathbb{P}(1, 1, 1, 1, 2, 3)$ given by

\begin{equation}
\begin{cases}
r \bar{v} = w - \gamma stu, \\
r(w + \gamma stu) = \bar{v}^2 + 3\mu \bar{v}(s^2 + t^2 + u^2) + 3\mu^2(s^2 + t^2 + u^2)^2 - g_4(s, t, u).
\end{cases}
\end{equation}

Now excluding the variable $w$ using the first equation in (8.4) and expressing $\bar{v}$ in terms of $s$, $t$, $u$, and $v$ by (8.1), we obtain a quartic hypersurface in $\mathbb{P}(1, 1, 1, 1, 2)$ with homogeneous coordinates $s$, $t$, $u$, $r$, and $v$ that is given by

\[ r(r \bar{v} + 2\gamma stu) = \bar{v}^2 + 3\mu \bar{v}(s^2 + t^2 + u^2) + 3\mu^2(s^2 + t^2 + u^2)^2 - g_4(s, t, u). \]

or equivalently by

\begin{equation}
v^2 + v(\mu(s^2 + t^2 + u^2) - r^2) + \mu^2(s^2 + t^2 + u^2)^2 - g_4(s, t, u) + \mu r^2(s^2 + t^2 + u^2) - 2\gamma r stu = 0.
\end{equation}

We denote this 3-fold by $W$.

We have constructed a birational map $V \dashrightarrow W$ that fits into the following $\mathfrak{G}'$-equivariant diagram

\begin{equation}
\begin{tikzcd}
\hat{V} \arrow{r} \arrow{d} & W \\
V
\end{tikzcd}
\end{equation}
Lemma 8.8. Let $\mathcal{U} = \text{Pic}(S) \otimes \mathbb{C}$. One has an isomorphism of $\mathfrak{G}'$-representations
\begin{equation}
\mathcal{U} \cong \mathbb{I} \oplus \mathbb{I}' \oplus \mathcal{W}_3 \oplus \mathcal{W}_3',
\end{equation}
where $\mathbb{I}$ is the trivial representation, $\mathbb{I}'$ is the sign representation, and $\mathcal{W}_3$ and $\mathcal{W}_3'$ are non-isomorphic irreducible three-dimensional representations.

Proof. Recall from (8.5) that the surface $S$ is given in $\mathbb{P}(1,1,1,2)$ with weighted homogeneous coordinates $s,t,u,$ and $v$ by equation
\[ v^2 + \frac{2\lambda}{3}v(s^2 + t^2 + u^2) + \frac{4\lambda^2}{9}(s^2 + t^2 + u^2)^2 - g_4(s,t,u) = 0, \]
where
\[ g_4(s,t,u) = \frac{\lambda^2 + 12}{3}(s^2 + t^4 + u^4) + \frac{2(\lambda^2 + 6\lambda)}{3}(t^2u^2 + s^2u^2 + t^2s^2). \]
As before, the parameter $\lambda$ varies in $\mathbb{C} \setminus \{ \pm 2, -1 \}$.

Let $v$ be a new variable defined as
\[ v = \frac{v}{2} + \frac{\lambda}{6}(s^2 + t^2 + u^2). \]
One can verify that, after this change of coordinates, $S$ is given by the following equation in $\mathbb{P}(1,1,1,2)$ with weighted homogeneous coordinates $s,t,u,$ and $v$, cf. (8.7):
\[ v^2 = s^4 + t^4 + u^4 + \lambda(t^2u^2 + s^2u^2 + t^2s^2). \]

Note that $\mathfrak{G}'$ is the subgroup in $\text{Aut}(S)$ generated by the transformations
\begin{align*}
[s : t : u : v] &\mapsto [-s : -t : u : v], \\
[s : t : u : v] &\mapsto [u : s : t : v], \\
[s : t : u : v] &\mapsto [t : s : u : v].
\end{align*}

Let $\mathfrak{G}''$ be the subgroup in $\text{Aut}(S)$ generated by the transformations
\begin{align*}
[s : t : u : v] &\mapsto [-s : -t : u : v], \\
[s : t : u : v] &\mapsto [u : s : t : v], \\
[s : t : u : v] &\mapsto [t : s : u : -v].
\end{align*}
Then $\mathcal{G}'' \cong \mathcal{G}'$, but these subgroups are not conjugate in $\text{Aut}(S)$. They intersect by the even elements, and every odd element of $\mathcal{G}'$ differs from the corresponding element of $\mathcal{G}''$ by the Galois involution of the anticanonical double cover $S \to \mathbb{P}^2$. This involution acts as a multiplication by $-1$ on the orthogonal complement to $K_S$ with respect to the intersection form in $\text{Pic}(S) \otimes \mathbb{C}$. Thus, to prove (8.9), it is enough to show that

$$U \cong \mathbb{I}^{\oplus 2} \oplus W_3 \oplus W'_3$$

as a representation of the group $\mathcal{G}''$.

For ease of notation, take $\alpha, \beta \in \mathbb{C}$ so that

$$\alpha^2 = \frac{-\lambda + 2\sqrt{-\lambda - 1}}{\lambda + 2} \quad \text{and} \quad \beta = \frac{\lambda}{2}(1 + \alpha^2).$$

Consider the following twelve $(-1)$-curves on the surface $S$:

- $L_1 : s + \alpha t = v - \beta t^2 - u^2 = 0$;
- $L_2 : s - \alpha t = v - \beta t^2 - u^2 = 0$;
- $L_3 : t + \alpha s = v + \beta s^2 + u^2 = 0$;
- $L_4 : t - \alpha s = v + \beta s^2 + u^2 = 0$;
- $L_5 : t + \alpha u = v - \beta u^2 - s^2 = 0$;
- $L_6 : t - \alpha u = v - \beta u^2 - s^2 = 0$;
- $L_7 : s + \alpha u = v + \beta u^2 + t^2 = 0$;
- $L_8 : s - \alpha u = v + \beta u^2 + t^2 = 0$;
- $L_9 : u + \alpha t = v + \beta t^2 + s^2 = 0$;
- $L_{10} : u - \alpha t = v + \beta t^2 + s^2 = 0$;
- $L_{11} : u + \alpha s = v - \beta s^2 - t^2 = 0$;
- $L_{12} : u - \alpha s = v - \beta s^2 - t^2 = 0$.

They form a single $\mathcal{G}''$-orbit. Moreover, these 12 curves split into a disjoint union of the following pairs of intersecting lines:

- $L_1 \cup L_2$, $L_3 \cup L_4$, $L_5 \cup L_6$, $L_7 \cup L_8$, $L_9 \cup L_{10}$, $L_{11} \cup L_{12}$.

Hence, there exists a $\mathcal{G}''$-equivariant conic bundle $\zeta : S \to \mathbb{P}^1$ such that these pairs are exactly its singular fibers. This implies that $\text{Pic}(S)^{\mathcal{G}''}$ is generated by $K_S$ and a fiber of this conic bundle. In particular, the surface $S$ is not $\mathcal{G}''$-minimal. With [DI09 Table 7], we conclude that $\mathcal{G}''$ is the odd lift of $\mathcal{G}_4$ to $\text{Aut}(S)$ (see [DI09 §6.6] for the terminology).

Therefore, the subgroup $\mathcal{G}'$ is the even lift of $\mathcal{G}_4$ to $\text{Aut}(S)$. Hence, by [DI09 Table 7], the surface $S$ is $\mathcal{G}'$-minimal, so that $U$ contains a unique trivial $\mathcal{G}'$-representation (generated by $K_S$). This in turn implies that $U$ does not contain summands isomorphic to the sign representation of the group $\mathcal{G}''$.

As $\mathcal{G}''$-representation, $U$ splits as

$$(8.10) \quad U \cong \mathbb{I}^{\oplus 2} \oplus \overline{U},$$

where $\overline{U}$ is some six-dimensional representation of $\mathcal{G}''$ that does not contain one-dimensional subrepresentations. We conclude that $\overline{U}$ splits into a sum of two- and three-dimensional irreducible $\mathcal{G}''$-representations. If there is a two-dimensional summand in $\overline{U}$, then it must be a sum of three two-dimensional summands. In this case the action of $\mathcal{G}''$ on $\text{Pic}(S)$ would be not faithful, which contradicts [Dol12 Corollary 8.2.40]. Therefore, we see that $\overline{U}$ is a sum of two three-dimensional irreducible representations of $\mathcal{G}''$. Note that in the splitting (8.10), the summand $\mathbb{I}^{\oplus 2}$ is generated by $K_S$ and a fiber of the conic bundle $\zeta$, while $L_1, L_3, L_5, L_7, L_9$, and $L_{11}$ form a basis in $\overline{U}$.

Let $\sigma$ be the element of the group $\mathcal{G}''$ that acts by

$$[s : t : u : v] \mapsto [t : s : u : -v].$$

Then

$$\sigma(L_1) = L_3, \quad \sigma(L_3) = L_1, \quad \sigma(L_5) = L_7, \quad \sigma(L_7) = L_5, \quad \sigma(L_9) = L_{11}, \quad \sigma(L_{11}) = L_9.$$

Thus, the trace of $\sigma$ in $\overline{U}$ equals 0. The element $\sigma$ corresponds to a transposition in $\mathcal{G}'' \cong \mathcal{G}_4$. This means that $\overline{U} \cong W_3 \oplus W'_3$ as $\mathcal{G}'$-representation. Therefore, the isomorphism (8.9) of $\mathcal{G}'$-representations holds.

□

34
The commutative diagram (8.6) gives a surjective $\mathcal{G}'$-module homomorphism of $\text{Cl}(V)$ onto $\text{Cl}(W)$ with one-dimensional kernel generated by the surface $\Pi_-$. On the other hand, restricting divisors in $\text{Cl}(W)$ to $S$, we obtain a $\mathcal{G}'$-module homomorphism

$$\text{Cl}(W) \to \text{Pic}(S),$$

which is injective (cf. [Pro13, Corollary 3.9.3]). Note that $\text{Cl}(W)$ is of rank 7, while $\text{Pic}(S)$ is of rank 8.

As $\mathcal{G}'$-representations, we have

$$\text{Cl}(V) \otimes \mathbb{C} \cong \mathbb{I} \oplus \mathbb{V},$$

where $\mathbb{I}$ is a trivial $\mathcal{G}'$-representation, and $\mathbb{V}$ is some six-dimensional $\mathcal{G}'$-representation. Note that the summand $\mathbb{I} \oplus \mathbb{V}$ is generated by $K_V$ and $\Pi_-$. We see that $\mathbb{V}$ is a subrepresentation of $\text{Pic}(S) \otimes \mathbb{C}$, so that $\mathbb{V}$ is a sum of two irreducible three-dimensional $\mathcal{G}'$-representations $W_3$ and $W_3'$ by Lemma 8.8.

As a by-product, we obtain

**Corollary 8.11.** There is an isomorphism of $\mathcal{G}'$-representations

$$\text{Cl}(V) \otimes \mathbb{C} \cong \mathbb{I} \oplus \mathbb{W}_3 \oplus \mathbb{W}_3'.$$

In particular, $\text{rk} \text{Cl}(V)^{\mathcal{G}'} = 2$ and $\text{rk} \text{Cl}(W)^{\mathcal{G}'} = 1$.

Recall that the subgroups $\mathcal{G}$ and $\mathcal{G}'$ are both isomorphic to $\mathfrak{S}_4$. They intersect by the even elements, and every odd element of $\mathcal{G}$ differs from the corresponding element of $\mathcal{G}'$ by the Galois involution $\tau$. This involution acts as a multiplication by $-1$ on the orthogonal complement, with respect to the intersection form $(1.2)$, to $K_V$ in $\text{Cl}(V) \otimes \mathbb{C}$. Thus, Corollary 8.11 implies that $\text{Cl}(V) \otimes \mathbb{C}$ contains a unique trivial subrepresentation of the group $\mathcal{G}$.

**Corollary 8.12.** One has $\text{rk} \text{Cl}(V)^{\mathcal{G}} = 1$.

### 9. Birational rigidity

In this section we study $G$-birationally rigidity of nodal double Veronese cones.

Let $V$ be a nodal del Pezzo 3-fold of degree 1 (not necessarily with 28 nodes). Then $V$ can be given in $\mathbb{P}(1, 1, 1, 2, 3)$ with weighted homogeneous coordinates $s, t, u, v,$ and $w$ (of weights 1, 1, 1, 2, and 3, respectively) by equation

$$w^2 = v^3 + vh_4(s, t, u) + h_6(s, t, u)$$

for some homogeneous polynomials $h_4(s, t, u)$ and $h_6(s, t, u)$ of degree 4 and 6, respectively. Then

$$-K_V \sim 2H,$$

where $H$ is an ample Cartier divisor on $V$ such that $H^3 = 1$. The linear system $|H|$ has one base point, which we denote by $O$. Recall that the 3-fold $V$ is smooth at the point $O$.

The linear system $|2H|$ is free from base points and gives a double cover $V \to \mathbb{P}(1, 1, 1, 2)$. As before, denote by $\tau$ the Galois involution of this double cover.

Let $\kappa: V \to \mathbb{P}^2$ be the projection given by

$$[s : t : u : v : w] \mapsto [s : t : u].$$

Then $\kappa$ is a rational map given by the linear system $|H|$. In particular, $\kappa$ is $\text{Aut}(V)$-equivariant. Furthermore, there exists an $\text{Aut}(V)$-equivariant commutative diagram
where $\psi$ is the blow up at the point $O$, and $\tilde{\kappa}$ is a morphism whose general fiber is an elliptic curve. Note that every fiber of the morphism $\tilde{\kappa}$ is irreducible. Moreover, we have an exact sequence of groups

$$1 \longrightarrow \Gamma \longrightarrow \text{Aut}(V) \longrightarrow \text{Aut}(\mathbb{P}^2),$$

where $\Gamma$ is a finite subgroup in $\text{Aut}(V)$ that contains $\tau$. If $h_4(x, y, z)$ is not a zero polynomial, then $\Gamma$ is generated by $\tau$. If $h_4(x, y, z)$ is a zero polynomial, then $\Gamma$ is a cyclic group of order 6 that is generated by $\tau$ and a map given by

$[s : t : u : v : w] \mapsto [s : t : \epsilon_3 v : w],$

where $\epsilon_3$ is a primitive cube root of unity (cf. [DI09 §6.7]).

Let $G$ be a finite subgroup of $\text{Aut}(V)$. Denote its image in $\text{Aut}(\mathbb{P}^2)$ by $\mathcal{G}$. Suppose that $\text{rk Cl}^G(V) = 1$, so that $V$ is a $G$-Mori fibre space (see [CST09, Definition 1.1.5]). If $\mathbb{P}^2$ contains a $\mathcal{G}$-fixed point, then there exists a $\mathcal{G}$-equivariant commutative diagram as follows:

Here $\mathbb{P}^2 \rightarrow \mathbb{P}^1$ is the projection from the $\mathcal{G}$-fixed point, $\alpha$ is the maximal extraction whose center is the fiber of $\kappa$ over the $\mathcal{G}$-fixed point, and $\nu$ is a fibration into del Pezzo surfaces of degree 1. Thus, in this case, the 3-fold $V$ cannot be $G$-birationally rigid.

If $V$ is smooth and $\mathbb{P}^2$ contains no $\mathcal{G}$-fixed points, then $V$ is $G$-birationally super-rigid. This follows from [Gri03] and [Gri04] (cf. [CS09, Remark 1.19]). It is conjectured that the following two conditions are equivalent for a nodal double Veronese cone $V$ with an action of a finite group $G$ such that $\text{rk Cl}(V)^G = 1$:

- $\mathbb{P}^2$ does not contain $\mathcal{G}$-fixed points,
- the 3-fold $V$ is $G$-birationally rigid.

At present, its proof is out of reach. Instead, we give a very simple proof of a weaker result, which implies Theorem [L7]. To state the result, note that a surface $\Pi$ in the 3-fold $V$ is said to be a plane if $\Pi \cong \mathbb{P}^2$ and $H^2 \cdot \Pi = 1$. For instance, by [Pro13 Theorem 7.2] every 28-nodal double Veronese cone contains exactly 126 planes.

**Theorem 9.1.** Let $V$ be a nodal double Veronese cone with an action of a finite group $G$ such that $\text{rk Cl}(V)^G = 1$. Suppose that the following three conditions are satisfied:

1. $\mathbb{P}^2$ does not contain $\mathcal{G}$-fixed points;
2. the singular locus $\text{Sing}(V)$ does not contain $G$-orbits of length 3;
3. for every $G$-irreducible curve $D$ in $V$ such that $H \cdot D$ is either 2 or 3, and $\kappa(D)$ is a curve in $\mathbb{P}^2$ of degree $H \cdot D$, there is a plane in $V$ that contains $D$.

Then $V$ is $G$-birationally super-rigid.

**Corollary 9.2.** Let $V$ and $G$ be as in Theorem 9.1. Suppose that $\mathbb{P}^2$ does not contain $\mathcal{G}$-fixed points. If $\mathbb{P}^2$ does not contain $\mathcal{G}$-invariant curves of degree 2 or 3, then $V$ is $G$-birationally super-rigid.

**Remark 9.3.** We cannot drop condition (2) in Theorem 9.1. Suppose that $\mathbb{P}^2$ does not contain $\mathcal{G}$-fixed points, but $\text{Sing}(V)$ contains a $G$-orbit of length 3. Let $\beta : \tilde{V} \rightarrow V$ be the blow up at this $G$-orbit. Then it follows from [JIR06] and [CPS05 Theorem 1.5] that there exists a crepant $G$-birational
morphism $\nu: \tilde{V} \rightarrow X$ such that $X$ is a double cover of $\mathbb{P}^3$ branched in an irreducible sextic surface. Let $\iota$ be the involution in $\text{Aut}(X)$ of this double cover, and put

$$\rho = \beta \circ \nu^{-1} \circ \iota \circ \nu \circ \beta^{-1}.$$ 

Then $\rho \in \text{Bir}^G(V)$. Moreover, if $\nu$ is small, then $\rho$ is not biregular.

Before proving Theorem 1.7, let us use it to prove Theorem 1.7.

**Proof of Theorem 1.7.** Suppose that the 28-nodal double Veronese cone $V$ is $G$-birationally rigid. Then the group $\overline{G}$ does not have fixed points on $\mathbb{P}^2$, and thus also has no fixed points on its projectively dual surface. Let $C$ be the smooth plane quartic curve that is constructed as the projectively dual curve of the discriminant curve $\overline{\rho}$ of the half-anticanonical rational elliptic fibration $\kappa: V \dashrightarrow \mathbb{P}^2$ (see Theorem 1.3 or Lemma 6.2). Then the group $\overline{G}$ acts faithfully on $C$. We see from Lemma 2.7 that $C$ can be given by equation (1.6), the group $\overline{G}$ acts faithfully on $\overline{G}$ of the half-anticanonical rational elliptic fibration $\kappa: V \dashrightarrow \mathbb{P}^2$ (see Theorem 1.3 and formula (5.10), we conclude that $V$ is a double Veronese cone from Example 1.5. Furthermore, by Theorem 1.4 the group $G$ contains a subgroup isomorphic to $S_4$. Now it follows from Corollary 8.11 that $G$ contains a subgroup conjugate to $G$.

Now we suppose that $V$ is a double Veronese cone from Example 1.5 and $G = \mathcal{G}$. Then $\mathbb{P}^2$ does not contain $\overline{G}$-fixed points, and $\text{rk Cl}(V)^G = 1$ by Corollary 8.12. To complete the proof, we have to show that $V$ is $G$-birationally super-rigid. Suppose that this is not a case. Let us seek for a contradiction.

Note that $\overline{G} \cong \mathcal{G}_4$, and $\mathbb{P}^2$ contains a unique $\overline{G}$-orbit of length 3. This orbit consists of the points $[0:0:1]$, $[0:1:0]$ and $[1:0:0]$. Taking partial derivatives of (5.10) and using the expressions for $g_2$ and $g_6$ provided in Example 1.5 we see that $\text{Sing}(V)$ does not contain points that are mapped by $\kappa$ to $[0:0:1]$, $[0:1:0]$ or $[1:0:0]$. In particular, we see that the singular locus $\text{Sing}(V)$ does not contain $\overline{G}$-orbits of length 3.

Using Theorem 9.1 we conclude that $V$ contains a $G$-irreducible curve $D$ on $V$ such that $H \cdot D$ is either 2 or 3, the curve $D$ is not contained in any plane on $V$, and $\kappa(D)$ is a curve in $\mathbb{P}^2$ of degree $H \cdot D$.

Observe that there exist a unique $\overline{G}$-invariant conic and a unique $\overline{G}$-invariant cubic curve in $\mathbb{P}^2$. The former curve is given by $s^2 + t^2 + u^2 = 0$, and the latter curve is given by $stu = 0$.

Suppose that $H \cdot D = 3$. Then $\kappa(D)$ is given by $stu = 0$, so that $D$ consists of three irreducible components that are mapped isomorphically by $\kappa$ to the lines $s = 0$, $t = 0$ and $u = 0$ in $\mathbb{P}^2$.

Let $D_s$ be the irreducible component of the curve $D$ that is mapped by $\kappa$ to the line $s = 0$. Then the stabilizer $G_s$ of $D_s$ in $G \cong \mathcal{G}_4$ is isomorphic to the dihedral group of order 8. However, its action on $D_s$ is not faithful, but the action of its quotient isomorphic to $\mu_2 \times \mu_2$ is faithful. Therefore, a general $G_s$-orbit in $D_s$ has length 4. Consider the pencil $\mathcal{R}$ of $G$-invariant surfaces in $V$ generated by the surfaces $v = 0$ and $s^2 + t^2 + u^2 = 0$. Since a surface from $\mathcal{R}$ has intersection number 2 with $D_s$, we conclude that there is a surface $R$ in $\mathcal{R}$ that contains $D_s$. Since $R$ is $G$-invariant, it contains the whole curve $D$.

The surface $R$ is given by equation

$$v = \mu(s^2 + t^2 + u^2)$$

for some $\mu \in \mathbb{C}$. Thus, the curve $D$ is contained in the subset in $V$ that is cut out by

$$v = \mu(s^2 + t^2 + u^2),$$

$$stu = 0.$$ 

If $\mu = \frac{2A}{3}$, then the equation $v = \mu(s^2 + t^2 + u^2)$ cuts out two planes in $V$, which are given by

$$v = \mu(s^2 + t^2 + u^2),$$

$$w = \gamma stu,$$
where $\gamma = \pm 2(\lambda - 2)\sqrt{\lambda + 1}$ (see \textit{[8.3]}). Thus, in this case, the curve $D$ is contained in a plane, which is impossible by assumption. Hence, we conclude that $\mu \neq \frac{2\lambda}{3}$.

We see that the irreducible component $D_s$ is contained in the subset in $V$ that is cut out by

$$
\begin{cases}
v = \mu(t^2 + u^2), \\
s = 0.
\end{cases}
$$

If this subset were irreducible and reduced, then it would coincide with $D_s$, which would contradict $H \cdot D_s = 1$. Hence, the above subset is either reducible or non-reduced. Algebraically, this simply means that the polynomial

$$P(t, u) = \mu^3(t^2 + u^2)^3 - \mu g_1(0, t, u)(t^2 + u^2) + g_6(0, t, u)$$

must be a complete square (this includes the possibility for the above polynomial to be zero, which corresponds to the non-reduced case). The polynomial $P(t, u)$ simplifies as

$$
\left(\mu^3 - \mu \frac{\lambda^2 + 12}{3} - \frac{2\lambda(\lambda - 6)(\lambda + 6)}{27}\right)(t^2 + u^2)^3 - 4(\lambda - 2)\left(\mu - \frac{2\lambda}{3}\right)(t^2 + u^2)t^2u^2.
$$

This shows that the polynomial $P(t, u)$ cannot be a zero polynomial because $\lambda \neq 2$ and $\mu \neq \frac{2\lambda}{3}$. Suppose that $P(t, u)$ is a complete square. Then it must be of the form

$$P(t, u) = (a_3t^3 + a_2t^2u + a_1tu^2 + a_0u^3)^2,$$

where $a_i$’s are constants depending on $\lambda$ and $\mu$. We can see directly from the simplified $P(t, u)$ above that $P(t, u)$ is invariant under switching variables $t$ and $u$ and that it contains $t$ and $u$ with only even exponents. We therefore obtain

$$a_0^2 = a_3^2, \quad a_2^2 + 2a_0a_2 = a_2^2 + 2a_1a_3, \quad a_0a_1 = a_2a_3 = 0, \quad a_0a_3 + a_1a_2 = 0.$$

However, these yield $a_0 = a_1 = a_2 = a_3 = 0$, which is impossible. Consequently, one has $H \cdot D \neq 3$.

We see that $H \cdot D = 2$. Then $\kappa(D)$ is given by equation $s^2 + t^2 + u^2 = 0$ in $\mathbb{P}^2$. In particular, one has $D \cong \mathbb{P}^1$. The action of $G \cong S_4$ on $D$ is faithful, so that any $G$-orbit in $D$ has length at least 6. Consider the pencil $\mathcal{R}$ as above. Since a surface from $\mathcal{R}$ has intersection number 4 with $D_s$, we conclude that every surface in $\mathcal{R}$ contains $D$. In particular, $D$ is contained in a surface given by equation

$$v = \frac{2\lambda}{3}(s^2 + t^2 + u^2).$$

As above, we conclude that $D$ is contained in a plane, which gives a contradiction. This completes the proof of Theorem \ref{thm:main}. \hfill \Box

Now we are equipped to prove Theorem \ref{thm:main}. Recall that $V$ is a nodal double Veronese cone with an action of a finite group $G$ such that $\rk\Cl(V)^G = 1$, and assumptions (1)–(3) of Theorem \ref{thm:main} hold. Namely, we suppose that $\mathbb{P}^2$ does not contain $\overline{G}$-fixed points; that the singular locus $\Sing(V)$ does not contain $G$-orbits of length 3; that for any $G$-irreducible curve $D$ in $V$ such that $H \cdot D$ is either 2 or 3, and $\kappa(D)$ is a curve in $\mathbb{P}^2$ of degree $H \cdot D$, there is a plane in $V$ containing the curve $D$.

\textit{Remark 9.4.} Since there are no $\overline{G}$-fixed points on $\mathbb{P}^2$, there are also no $\overline{G}$-invariant lines. This implies that there are no $\overline{G}$-orbits contained in a line. In other words, every $\overline{G}$-orbit contains three non-collinear points, and in particular no $\overline{G}$-orbits of length 2. Furthermore, by Lemma \ref{lem:noncollinear} every $\overline{G}$-orbit contains four points such that no three of them are collinear.

To prove Theorem \ref{thm:main}, we have to show that the 3-fold $V$ is $G$-birationally super-rigid. Suppose that it is not. Then there exists a $G$-invariant mobile linear system $\mathcal{M}$ on the 3-fold $V$ such that

$$\mathcal{M} \sim nH,$$

and the log pair $(V, \frac{2}{n}\mathcal{M})$ is not canonical (see for instance [CS16, Theorem 3.3.1]).

38
Let $Z$ be a $G$-center of non-canonical singularities of the log pair $(V, \frac{2}{3}M)$. Recall that $O$ denotes the (unique) base point of the linear system $|H|$ on $V$, and $O$ is a smooth point of $V$.

**Lemma 9.5.** The $G$-center $Z$ cannot be the point $O$.

**Proof.** Let $M$ be a general surface in $\mathcal{M}$, and let $E$ be a general fiber of the map $\kappa$. Then $E \not\subset M$, so that

$$n = M \cdot E \geq \text{mult}_O(E) \cdot \text{mult}_O(M) \geq \text{mult}_O(M).$$

On the other hand, the Zariski tangent space $T_O, V$ is an irreducible representation of the group $G$, because $\mathbb{P}^2$ does not contain $G$-fixed points. Thus, using Lemma 2.4, we conclude that $O$ is not a center of non-canonical singularities of the log pair $(V, \frac{2}{3}M)$. \hfill $\square$

**Lemma 9.6.** If $Z$ is 0-dimensional, then $Z \subset \text{Sing}(V)$.

**Proof.** Suppose that the $G$-orbit $Z$ consists of smooth points of the 3-fold $V$. Let $M_1$ and $M_2$ be general surfaces in the linear system $\mathcal{M}$. Then

$$\text{mult}_P(M_1 \cdot M_2) > n^2$$

for every $P \in Z$ by [Cor00, Corollary 3.4]. Let us show that this leads to a contradiction.

By Lemma 9.5, we have $Z \neq O$, so that $\kappa(Z)$ is a well-defined $G$-orbit. Moreover, $\kappa(Z)$ consists of at least 3 points, and contains three non-collinear points by Remark 9.4. Denote them by $P_1$, $P_2$ and $P_3$.

Let $E_1$, $E_2$ and $E_3$ be fibers of the map $\kappa$ over the points $P_1$, $P_2$ and $P_3$, respectively. Then

$$M_1 \cdot M_2 = m(E_1 + E_2 + E_3) + \Delta,$$

where $m$ is a non-negative integer, and $\Delta$ is an effective one-cycle whose support does not contain the curves $E_1$, $E_2$ and $E_3$. Then $m \leq \frac{n^2}{3}$, since

$$n^2 = H \cdot M_1 \cdot M_2 = H \cdot \left( m(E_1 + E_2 + E_3) + \Delta \right) = 3m + H \cdot \Delta \geq 3m.$$

Let $O_1$, $O_2$ and $O_3$ be points in $Z$ that are mapped to $P_1$, $P_2$ and $P_3$, respectively. Let $\delta = \text{mult}_{O_1}(E_i)$. Then either $\delta = 1$ or $\delta = 2$. Moreover, it follows from (9.7) that

$$\text{mult}_{O_1}(\Delta) > n^2 - m\delta$$

for each point $O_i$.

Let $\mathcal{B}$ be a linear subsystem in $|2H|$ consisting of all surfaces that contain the curves $E_1$, $E_2$ and $E_3$. Then $\mathcal{B}$ does not have other base curves, since $P_1$, $P_2$ and $P_3$ are not collinear. Thus, for a general surface $B$ in $\mathcal{B}$, we have

$$2n^2 - 6m = B \cdot \Delta \geq \sum_{i=1}^{3} \text{mult}_{O_i}(\Delta) > 3\left( n^2 - m\delta \right).$$

This implies

$$-4m \geq m\delta - 6m > n^2,$$

which is a contradiction. \hfill $\square$

**Lemma 9.8.** The center $Z$ is 1-dimensional.

**Proof.** Suppose that $\dim Z = 0$, so that $Z$ is a $G$-orbit. Then $Z \subset \text{Sing}(V)$ by Lemma 9.6. Let $r$ be the length of the $G$-orbit $\kappa(Z)$. Note that $r \geq 3$ by Remark 9.4. Denote the points of $\kappa(Z)$ by $P_1, \ldots, P_r$. Let $E_i$ be the fiber of the map $\kappa$ over the point $P_i$. Then $E_i$ is an irreducible curve because $E_i \cdot H = 1$. Since the arithmetic genus of $E_i$ equals 1, we see that $E_i$ has at most one singular point, and thus contains at most one singular point of the 3-fold $V$. Hence, since $E_i \cap Z \neq \emptyset$, each curve $E_i$ contains exactly one singular point of $V$, which must be a singular point of the curve $E_i$. In particular, we see that the length of the $G$-orbit $Z$ also equals $r$. 39
Let $O_i$ be the singular point of the curve $E_i$. Then $Z$ consists of the points $O_1, \ldots, O_r$. By assumption, we have $r \geq 4$.

The $\mathcal{G}$-orbit $\kappa(Z)$ contains four points in $\mathbb{P}^2$ such that no three of them are collinear by Remark 9.1. Without loss of generality, we may assume that these points are $P_1, P_2, P_3$, and $P_4$. Let $\mathcal{B}$ be a linear subsystem in $|2H|$ consisting of all surfaces that contain the curves $E_1, E_2, E_3$ and $E_4$. Then $\mathcal{B}$ does not contain other base curves.

Let $\beta : \mathbb{V} \to V$ be the blow up of the points $O_1, O_2, O_3$ and $O_4$, and let $F_1, F_2, F_3, F_4$ be the $\beta$-exceptional surfaces that are mapped to the points $O_1, O_2, O_3, O_4$, respectively. Denote by $\overline{\mathcal{B}}$ the proper transforms on $\overline{\mathbb{V}}$ of the linear system $\mathcal{B}$. Then

$$-K_{\overline{\mathbb{V}}} \sim \overline{\mathcal{B}} \sim \beta^*(2H) - (F_1 + F_2 + F_3 + F_4),$$

which implies that the divisor $-K_{\overline{\mathbb{V}}}$ is nef, because it intersects the proper transform of each curve $E_i$ trivially.

Denote by $\overline{\mathcal{M}}$ the proper transform of the linear system $\mathcal{M}$ on the 3-fold $\overline{\mathbb{V}}$. Then

$$\overline{\mathcal{M}} \sim_{\mathbb{Q}} \beta^*(nH) - m(F_1 + F_2 + F_3 + F_4)$$

for some non-negative rational number $m$. Let $\overline{\mathcal{M}}_1$ and $\overline{\mathcal{M}}_2$ be general surfaces in $\overline{\mathcal{M}}$. Then

$$0 \leq \overline{\mathcal{B}} \cdot \overline{\mathcal{M}}_1 \cdot \overline{\mathcal{M}}_2 = 2n^2 - 8m^2,$$

which gives $m \leq \frac{n}{2}$. This is impossible by [Cor00, Theorem 3.10].

Thus, Lemma 9.8 concludes that $Z$ is a $G$-irreducible curve. Denote by $Z_1, \ldots, Z_r$ the irreducible components of $Z$. Thus, if $r = 1$, then $Z = Z_1$ is an irreducible curve. In this case, $\kappa(Z)$ is neither a point nor a line, because $\mathbb{P}^2$ does not contain $\mathcal{G}$-fixed points. In particular, we see that $H \cdot Z \neq 1$.

Since $Z$ is a $G$-center of non-canonical singularities of the log pair $(V, \frac{2}{n} \mathcal{M})$, we have

$$\mathrm{mult}_{Z_i}(\mathcal{M}) > \frac{n}{2}.$$

Let $M_1$ and $M_2$ be general surfaces in $\mathcal{M}$. Then

$$n^2 = H \cdot M_1 \cdot M_2 \geq \sum_{i=1}^{r} \mathrm{mult}_{Z_i}(M_1 \cdot M_2) > \frac{n^2}{4} r H \cdot Z_i,$$

so that we have the following four possibilities:

(A) $r = 1$, $H \cdot Z = 2$, and $\kappa(Z)$ is a smooth conic in $\mathbb{P}^2$;
(B) $r = 1$, $H \cdot Z = 3$, and $\kappa(Z)$ is a smooth cubic in $\mathbb{P}^2$;
(C) $r = 3$, $H \cdot Z = 3$, and $\kappa(Z)$ is a union of three lines;
(D) $r = 3$, $H \cdot Z = 3$, and $\kappa(Z)$ is a $\mathcal{G}$-orbit of length 3.

We claim that the case (D) is impossible. Indeed, if $\kappa(Z)$ is a $\mathcal{G}$-orbit of length 3, then the linear system $|H|$ contains a surface $H_{12}$ passing through $Z_1$ and $Z_2$. Let $M$ be a general element of the linear system $\mathcal{M}$. Then

$$n = H \cdot M \cdot H_{12} \geq \mathrm{mult}_{Z_1}(M) + \mathrm{mult}_{Z_2}(M) > n,$$

which is absurd.

Thus, we see that $H \cdot Z$ is either 2 or 3 and that $\kappa(Z)$ is a curve of degree $H \cdot Z$. Therefore, by assumption, the 3-fold $V$ has a plane $\Pi$ that contains the curve $Z$. Let $L$ be a general line in this plane, so that $H \cdot L = 1$, the intersection $L \cap Z$ consists of exactly $H \cdot Z$ points, and $L$ is not contained in the base locus of the linear system $\mathcal{M}$. Then, for a general surface $M \in \mathcal{M}$, we have

$$n = L \cdot M \geq \mathrm{mult}_Z(M) \cdot |L \cap Z| \geq 2 \mathrm{mult}_Z(M) \geq 2 \mathrm{mult}_Z(\mathcal{M}) > n,$$

which is a contradiction. This completes the proof of Theorem 9.1.
10. Questions and problems

In this section we discuss several open questions concerning 28-nodal double Veronese cones.

**Del Pezzo surfaces of degree 2.** Let \( V \) be a 28-nodal double Veronese cone, let \( C \) be the plane quartic curve corresponding to \( V \) by Theorem \[13.3\] and let \( S \) be the del Pezzo surface of degree 2 constructed as the double cover of \( \mathbb{P}^2 \) branched along \( C \). We know from Corollary \[6.8\] that
\[
\text{Aut}(V) \cong \mu_2 \times \text{Aut}(C) \cong \text{Aut}(S),
\]
although there is no obvious choice for a natural isomorphism between \( \text{Aut}(V) \) and \( \text{Aut}(S) \). Also, one has
\[
\text{Cl}(V) \cong \mathbb{Z}^8 \cong \text{Pic}(S).
\]
Recall from [Pro13, Corollary 7.1.4] that the group \( \text{Aut}(V) \) acts faithfully on \( \text{Cl}(V) \), while by [Dol12, Corollary 8.2.40] the group \( \text{Aut}(S) \) acts faithfully on \( \text{Pic}(S) \). It would be interesting to know if there exists a natural identification of the corresponding representations. More precisely, we ask the following:

**Question 10.1.** Does there exist an isomorphism \( \text{Aut}(V) \cong \text{Aut}(S) \) under which \( \text{Cl}(V) \otimes \mathbb{C} \) is isomorphic to \( \text{Pic}(S) \otimes \mathbb{C} \) as representations of this group?

Recall that both \( \text{Cl}(V) \) and \( \text{Pic}(S) \) have a naturally defined intersection form. The canonical class \( K_V \) is invariant with respect to the action of the group \( \text{Aut}(V) \) on \( \text{Cl}(V) \), and the canonical class \( K_S \) is invariant with respect to the action of \( \text{Aut}(S) \) on \( \text{Pic}(S) \). Moreover, in some cases these are the only trivial subrepresentations in \( \text{Cl}(V) \otimes \mathbb{C} \) and \( \text{Pic}(S) \otimes \mathbb{C} \); for instance, this is the case when \( \text{Aut}(C) \cong \text{PSL}_2(\mathbb{F}_7) \). Therefore, if there exists a natural identification of automorphism groups as required in Question 10.1, then for any 28-nodal Veronese double cone \( V \) and the corresponding del Pezzo surface \( S \) there must exist an identification of the seven-dimensional representations of the group \( \text{Aut}(V) \cong \text{Aut}(S) \) in the orthogonal complement \( \text{Cl}(V)_{K_V} \otimes \mathbb{C} \) to \( K_V \) in \( \text{Cl}(V) \otimes \mathbb{C} \) and in the orthogonal complement \( \text{Pic}(S)_{K_S} \otimes \mathbb{C} \) to \( K_S \) in \( \text{Pic}(S) \otimes \mathbb{C} \).

Recall that both lattices \( \text{Cl}(V)_{K_V} \) and \( \text{Pic}(S)_{K_S} \) are isomorphic to the lattice \( E_7 \) (see [Pro13, Theorem 1.7] and [Pro13, Remark 1.8] for the former, and [DI09, §8.2.6] for the latter). We point out that despite this fact in general one cannot hope for an equivariant identification of the lattices \( \text{Cl}(V)_{K_V} \) and \( \text{Pic}(S)_{K_S} \) that takes into account the intersection forms, even if the answer to Question 10.1 is positive.

Indeed, let \( C \) be a smooth plane quartic curve with an action of the symmetric group \( S_4 \) as in Example 1.5. Let us use the notation of [8.11] and Lemma 8.8 that each of the \( \mathfrak{S}' \)-representations \( \text{Cl}(V) \otimes \mathbb{C} \) and \( \text{Pic}(S) \otimes \mathbb{C} \) contains a unique two-dimensional subrepresentation. This implies that the lattice \( \text{Cl}(V) \) contains a unique \( \mathfrak{S}' \)-invariant primitive sublattice \( \Lambda_V \) of rank 2, and the lattice \( \text{Pic}(S) \) contains a unique \( \mathfrak{S}' \)-invariant primitive sublattice \( \Lambda_S \) of rank 2. However, the sublattice \( \Lambda_V \) is generated by the half-anticanonical divisor \( H \) and the plane \( \Pi_- \), so that the intersection form on \( \Lambda_V \) is given by the matrix
\[
\begin{pmatrix}
H^2 & H \cdot \Pi_- \\
H \cdot \Pi_- & \Pi_-^2
\end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}.
\]

On the other hand, it follows from the proof of Lemma 8.8 that the sublattice \( \Lambda_S \) is generated by \( -K_S \) and a fiber \( F \) of a conic bundle, so that the intersection form on \( \Lambda_S \) is given by the matrix
\[
\begin{pmatrix}
K_S^2 & -K_S \cdot F \\
-K_S \cdot F & F^2
\end{pmatrix} = \begin{pmatrix} 2 & 2 \\ 2 & 0 \end{pmatrix}.
\]

Thus, we see that the lattices \( \Lambda_V \) and \( \Lambda_S \) are not isomorphic.

One situation when we can easily establish the isomorphism required in Question 10.1 is as follows. Let \( G \) be a subgroup in \( \text{Aut}(\mathbb{P}^3) \) such that there exists a \( G \)-invariant Aronhold heptad \( P_1, \ldots, P_7 \).
Then the diagram (7.24) is $G$-equivariant, which implies that $\Cl(V) \otimes \mathbb{C}$ is isomorphic to $\Pic(S) \otimes \mathbb{C}$ as $G$-representations.

**Elliptic fibration.** The following construction was pointed out to us by Alexander Kuznetsov. Let $C$ be a smooth plane quartic, and let $S$ be the corresponding del Pezzo surface of degree 2 with the anticanonical morphism $\varphi: S \to \mathbb{P}^2$. Let $\mathbb{P}^2$ be the projectively dual plane of $\mathbb{P}^2$. Let $p_1$ and $p_2$ be the projections of the flag variety

$$\mathcal{F} = \Fl(1,2,3) \subset \mathbb{P}^2 \times \mathbb{P}^2$$

to the first and the second factor of $\mathbb{P}^2 \times \mathbb{P}^2$, respectively. Consider the fiber product

$$
\begin{array}{ccc}
\mathbb{P}^2 & \xrightarrow{\varphi} & \mathcal{F} \\
\downarrow & & \downarrow \gamma \\
S & \xrightarrow{p_2} & \mathbb{P}^2
\end{array}
$$

Note that there is a natural action of the group $\text{Aut}(S) \cong \mu_2 \times \text{Aut}(C)$ on $Y$. The morphism

$$\kappa_Y = p_2 \circ \gamma: Y \to \mathbb{P}^2$$

is an elliptic fibration whose discriminant curve is projectively dual to $C$.

Now let $V$ be the 28-nodal double Veronese cone constructed from the plane quartic $C$ by Theorem 1.3. Then the half-anticanonical map $\kappa: V \dasharrow \mathbb{P}^2$ is a rational elliptic fibration. Let $\tilde{V}$ be the blow up of $V$ at the unique base point of $\kappa$, and let $\tilde{\kappa}: \tilde{V} \to \mathbb{P}^2$ be the corresponding regular elliptic fibration. Then the discriminant curve of $\tilde{\kappa}$ is projectively dual to $C$. Moreover, it follows from Lemma 3.9 that over every point in $\mathbb{P}^2$ the fibers of the elliptic fibrations $\tilde{\kappa}$ and $\kappa_Y$ are isomorphic to each other (cf. Lemma 6.3).

Furthermore, it follows from Lemma 3.9 that (at least over the complement to the discriminant curve) the elliptic fibration $\kappa_Y$ is the relative $\text{Pic}^2$ of the elliptic fibration $\tilde{\kappa}$. Indeed, let $E$ be a smooth fiber of $\tilde{\kappa}$, and let $P_1$ and $P_2$ be two points on $E$. Recall that $E$ is a proper transform of the base locus $E_Q$ of some pencil $Q$ of quadrics in $\mathbb{P}^3$. The two points $P_1, P_2 \in E_Q$ define a line $L$ passing through them. Thus they define a unique quadric $Q\in\mathbb{P}^3$ containing the line $L$, and also the family of lines on $Q$ which contains $L$. Note that the fiber of the elliptic fibration $\kappa_Y$ over the point $\tilde{\kappa}(E)$ can be identified with the double cover of $Q \cong \mathbb{P}^1$ branched in the locus of singular quadrics of $Q$ or, in other words, with the Hilbert scheme of lines contained in the quadrics of $Q$. Therefore, the pair of points $(P_1, P_2)$ defines a point on the fiber of $\kappa_Y$ over $\tilde{\kappa}(E)$. This point depends only on the class of the pair $(P_1, P_2)$ in $\text{Sym}^2(E)$, since every other pair from the same class determines the same quadric $Q$ and a line from the same family of lines on $Q$ where $L$ lies. We conclude that the fiber of $\kappa_Y$ over $\tilde{\kappa}(E)$ is identified with $\text{Pic}^2(E)$. It remains to notice that this construction can be performed in the family, and thus the assertion about the fibrations follows.

One of the consequences of the above construction is as follows. Since the elliptic fibration $\tilde{\kappa}$ is obtained by blowing up $V$ at a single point, it comes with a distinguished section (which corresponds to the eighth base point of the net of quadrics in the construction of $V$ from an Aronhold heptad). Therefore, there exist a natural birational map between $V$ and $Y$.

**Question 10.2.** Is there a more explicit geometric relation between the 3-fold $Y$ and the 28-nodal double Veronese cone $V$?

**Intersections of quadrics and cubics.** The following construction was also explained to us by Alexander Kuznetsov. Let $P_1, \ldots, P_8$ be a regular Cayley octad, and let $\mathcal{L}$ be the corresponding net of quadrics in $\mathbb{P}^3$. Then the lines contained in the quadrics of $\mathcal{L}$ are parameterized by a three-dimensional
variety $Z$ (cf. [Rei72, §1.2]). Then $Z$ can be regarded as a subvariety of the Grassmannian $\text{Gr}(2, 4)$. Let $U^\vee$ be the universal quotient bundle on $\text{Gr}(2, 4)$ (or, which is the same, the dual of the tautological subbundle). Furthermore, $Z$ can be described as the degeneracy locus of the morphism of vector bundles

$$\mathcal{O}_{\text{Gr}(2, 4)} \to S^2 U^\vee$$

corresponding to $L$. Therefore, the 3-fold $Z$ is an intersection of a quadric and a cubic in $\mathbb{P}^5$. Note that $Z$ has 28 singular points corresponding to the lines passing through pairs of points $P_i$ and $P_j$. In particular, its intermediate Jacobian is trivial.

**Question 10.3.** Is there a natural geometric relation between the 3-fold $Z$ and the 28-nodal double Veronese cone $V$ constructed from the net of quadrics $L$? Is the 3-fold $Z$ rational?

**Question 10.4.** Does the 3-fold $Z$ depend on the choice of the net of quadrics $L$, or only on the corresponding plane quartic curve?

**Other 3-folds constructed from plane quartics.** There are other interesting classes of 3-folds related to plane quartic curves. For instance, a construction due to S. Mukai assigns to a general plane quartic a smooth Fano 3-fold of genus 12 (and anticanonical degree 22), see [Muk92], [Muk04], and [RS00] for details.

**Question 10.5.** Is there a natural geometric relation between the 28-nodal double Veronese cone $V$ and the Fano 3-fold $V_{22}$ of genus 12 constructed from the same smooth plane quartic $C$?

We point out that both of the above varieties are rational, so there always exists a birational map between them. However, one cannot choose such a map to be $\text{Aut}(C)$-equivariant. Indeed, if $\text{Aut}(C) \cong \text{PSL}_2(\mathbb{F}_7)$, then both $V$ and $V_{22}$ are $\text{PSL}_2(\mathbb{F}_7)$-birationally super-rigid by Theorem [L7] and [CS12, Theorem 1.10].

**Degenerations.** The following question was asked by Vyacheslav Shokurov and Yuri Prokhorov.

**Question 10.6.** Can one extend the one-to-one correspondence between smooth plane quartics and 28-nodal double Veronese cones given by Theorem [L3] to the (mildly) singular case (like, double Veronese cones with $cA_1$-singularities, or double Veronese cones with 26 nodes and one nice $cA_2$-singularity, or plane quartics with a single node)? Furthermore, can one include in this one-to-one correspondence the plane quartic that is a union of a cuspidal cubic and its tangent line in the cusp (in other words, the quartic that gives rise to a del Pezzo surface of degree 2 with an $E_7$-singularity)?

**Appendix A. Computer-aided calculations**

This appendix explains, from a computational point of view, how (5.4) is obtained. In particular, a way to extract explicit formulae of the covariants $g_4(s, t, u)$ and $g_6(s, t, u)$ from a given plane quartic (5.1) is described, which enables us to produce concrete examples of 28-nodal double Veronese cones from smooth quartic curves as in Example [L5]. We point out that there is a method to write down the polynomial $g_4(s, t, u)$ using a smaller amount of explicit computations. It is based on the expression for the cubic invariant in the coefficients of the plane quartic given in [Sal52, §293] (see the end of [Ott13, §1]).

Since the denominator and the numerator of the $j$-function in (5.2) are symmetric polynomials in $x_1, x_2, x_3, x_4$, the $j$-function in (5.2) may be regarded as a rational function in $b_0, b_1, b_2, b_3, b_4$ of (5.3). Using the simple MAGMA ([BCP97]) function
Computing the numerator (N) and the denominator (D) in terms of symmetric functions

\[ Q<x_1,x_2,x_3,x_4> := \text{PolynomialRing}(\text{RationalField}(), 4); \]
\[ \text{Num}:=(x_1-x_2)^2*(x_4-x_3)^2-(x_1-x_3)*(x_4-x_2)*(x_4-x_1)*(x_3-x_2); \]
\[ D:=(x_1-x_2)^2*(x_1-x_3)^2*(x_1-x_4)^2*(x_2-x_3)^2*(x_2-x_4)^2*(x_3-x_4)^2; \]
\[ Q<b_1, b_2, b_3, b_4> := \text{PolynomialRing}(\text{RationalField}(), 4); \]
\[ I, D := \text{IsSymmetric}(\text{Num}, Q); \]
\[ I, D := \text{IsSymmetric}(\text{Den}, Q); \]
\[ Q; \]
\[ \text{N}; \]

we are able to obtain the denominator and the numerator of the j-function (respectively D and N), which after homogenization with respect to \( b_0 \) result in

\[
(x_1 - x_2)^2(x_4 - x_3)^2 - (x_1 - x_3)(x_4 - x_2)(x_4 - x_1)(x_3 - x_2) = \frac{1}{b_0^3} \left( -3b_1b_3 + 12b_0b_4 + b_2^2 \right);
\]
\[
(x_1 - x_2)^2(x_1 - x_3)^2(x_2 - x_1)^2(x_2 - x_3)^2(x_3 - x_4)^2 = \frac{1}{b_0^6} \left( -27b_1^4b_4^2 + 18b_1^3b_2b_3b_4 - 4b_1^2b_3^3 - 4b_1b_2^2b_3^2 + 144b_0b_1^2b_2b_3 - 6b_1b_2b_3^2b_4 - 80b_0b_1b_2b_3b_4 + 18b_0b_1b_2b_3^2 - 192b_0^2b_1b_2b_3 + 16b_0^3b_2b_4 - 4b_0b_3^2b_4 - 128b_0^2b_3^2b_4 + 144b_0^2b_2b_3b_4 - 27b_0^3b_3^2 + 256b_0^3b_4^2 \right).
\]

Therefore, regarded as a rational function in \( b_0, b_1, b_2, b_3, b_4 \), the j-function in \([5,2]\) can be expressed as follows:

\[
j(b_0, b_1, b_2, b_3, b_4) = \frac{2^8(-3b_1b_3 + 12b_0b_4 + b_2^3)^3}{\left\{ -27b_1^4b_4^2 + 18b_1^3b_2b_3b_4 - 4b_1^2b_3^3 - 4b_1b_2^2b_3^2 + 144b_0b_1^2b_2b_3 - 6b_1b_2b_3^2b_4 - 80b_0b_1b_2b_3b_4 + 18b_0b_1b_2b_3^2 - 192b_0^2b_1b_3b_4^2 + 16b_0^3b_2b_4 - 4b_0b_3^2b_4 - 128b_0^2b_3^2b_4 + 144b_0^2b_2b_3b_4 - 27b_0^3b_3^2 + 256b_0^3b_4^2 \right\}}
\]
\[
= \frac{1728}{4h_2(b_0, b_1, b_2, b_3, b_4)^3} - 27h_3(b_0, b_1, b_2, b_3, b_4)^2,
\]

where

\[
h_2(b_0, b_1, b_2, b_3, b_4) = \frac{1}{3} \left( -3b_1b_3 + 12b_0b_4 + b_2^2 \right);
\]
\[
h_3(b_0, b_1, b_2, b_3, b_4) = \frac{1}{27} \left( 72b_0b_2b_4 - 27b_0b_3^2 - 27b_0^2b_4 + 9b_1b_2b_3 - 2b_2^3 \right).
\]

Since \( b_0, \ldots, b_4 \) are homogeneous polynomials of degree 4 in \( s, t, \) and \( u \), we can obtain expressions for \( h_2(b_0, b_1, b_2, b_3, b_4) \) and \( h_3(b_0, b_1, b_2, b_3, b_4) \) as homogeneous polynomials of degrees 8 and 12, respectively, in \( s, t, u \). Starting with a quartic equation

\[
\sum_{i+j+k=4} a_{ijk}x^iy^jz^k = 0,
\]

where \( a_{ijk} \) are independent variables, we can calculate \( b_0, \ldots, b_4 \), using the identities given after \([5,3]\), as in the code below.
Calculating $h_2$ and $h_3$ in terms of $s, t, u$ with general coefficients $a_{ijk}$

\[
P < a_{400}, a_{310}, a_{301}, a_{220}, a_{202}, a_{211}, a_{130}, a_{112}, a_{121}, a_{103}, a_{040}, a_{031}, a_{022}, a_{013}, a_{004}, s, t, u > := \text{PolynomialRing}(\text{Rationals}(), 18);
\]

\[
b_0 := a_{004} s^4 - a_{103} s^3 u + a_{202} s^2 u^2 - a_{301} s u^3 + a_{400} u^4;
\]

\[
b_1 := 4 a_{004} s^3 t - a_{013} s^3 u - 3 a_{103} s^2 t u + a_{112} s^2 u^2 + 2 a_{202} s t u^2 - a_{211} s u^3 - a_{301} t u^3 + a_{310} u^4;
\]

\[
b_2 := 6 a_{004} s^2 t^2 - 3 a_{013} s^2 t u + a_{022} s^2 u^2 - 3 a_{103} s t^2 u + 2 a_{112} s t u^2 - a_{121} s u^3 - a_{202} t^2 u^2 - a_{211} t u^3 + a_{220} u^4;
\]

\[
b_3 := 4 a_{004} s t^3 - 3 a_{013} s t^2 u + 2 a_{022} s t u^2 - a_{031} s u^3 - a_{103} t^3 u + a_{112} t^2 u^2 - a_{121} t u^3 + a_{130} u^4;
\]

\[
b_4 := a_{004} t^4 - a_{013} t^3 u + a_{022} t^2 u^2 - a_{031} t u^3 + a_{040} u^4;
\]

\[
h_2 := -3 b_1 b_3 + b_2^2 + 12 b_4 b_0;
\]

\[
h_3 := \frac{4}{3} b_0 b_2 b_4 - b_0 b_3^2 - b_1^2 b_4 + \frac{1}{3} b_1 b_2 b_3 - \frac{2}{27} b_2^3;
\]

It can be checked, for example using the command `Factorisation(h2)`, that $h_2$ and $h_3$ are divisible by $u^4$ and $u^6$, respectively. Therefore, we are able to put

$\quad h_2(b_0, b_1, b_2, b_3, b_4) = u^4 g_4(s, t, u)$ \quad and \quad $h_3(b_0, b_1, b_2, b_3, b_4) = u^6 g_6(s, t, u),$

where $g_4(s, t, u)$ and $g_6(s, t, u)$ are homogeneous polynomials of degrees 4 and 6, respectively, in $s, t, u$. Consequently, the rational function $j(b_0, b_1, b_2, b_3, b_4)$ can be presented as a rational function $j_C$ in $\mathbb{P}^2$ with variables $s, t, u$ via

$\quad j_C(s, t, u) = 1728 \frac{4 g_4(s, t, u)^3}{4 g_4(s, t, u)^3 - 27 g_6(s, t, u)^2}.$
