Abstract
A new understanding of the notion of regularizer is proposed. It is argued that this new notion is more realistic than the old one and better fits the practical computational needs. An example of the regularizer in the new sense is given. A method for constructing regularizers in the new sense is proposed and justified.

1 Introduction

Let

\[ A(u) = g, \]

where \( A : X \to Y \) is a closed, possibly nonlinear, map from a Banach space \( X \) into a Banach space \( Y \). Problem (1.1) is called ill-posed if \( A \) is not a homeomorphism of \( X \) onto \( Y \), that is, either equation (1.1) does not have a solution, or the solution is non-unique, or the solution does not depend on \( g \) continuously. Let us assume that (1.1) has a solution \( u \) and this solution is unique but \( A^{-1} \) is not continuous. Given noisy data \( g_\delta, \|g_\delta - g\| \leq \delta \), one wants to construct a stable approximation \( u_\delta \) of the solution \( u \), \( \|u_\delta - u\| \to 0 \) as \( \delta \to 0 \). This is often done with the help of a regularizer. Traditionally (see, e.g., [2]) one calls a family of operators \( R_h \) a regularizer for problem (1.1) if:

a) \( R_h A(u) \to u \) as \( h \to \infty \) for any \( u \in D(A) \),

b) \( R_h g_\delta \) is defined for any \( g_\delta \in Y \) and there exists \( h(\delta) \to 0 \) as \( \delta \to 0 \) such that

\[ \|R_{h(\delta)} g_\delta - u\| \to 0 \] as \( \delta \to 0 \), \hspace{1cm} (\*)

where \( u \) solves (1.1). In this definition \( u \) is fixed and (\*) must hold for any \( g_\delta \in B(g, \delta) := \{ g_\delta : \|g_\delta - g\| \leq \delta \} \).

\textsuperscript{*}key words: ill-posed problems, regularizer, stable numerical differentiation, new notion of regularizer

\textsuperscript{†}AMS subject classification: 47A52, 65F22, 65J20
In practice one does not know the solution \( u \). The only available information is a family \( g_\delta \) and some priori information about the solution \( u \). This information very often consists of the knowledge that \( u \in \mathcal{K} \), where \( \mathcal{K} \) is a compactum in \( X \). Thus

\[
u \in S_\delta := \{ v : \| A(v) - g_\delta \| \leq \delta, \ v \in \mathcal{K} \}.\]

We assume that the operator \( A \) is known exactly, and we always assume that \( g_\delta \in B(g, \delta) \), where \( g = A(u) \).

It is natural to call a family of operators \( R(\delta) \) a regularizer (in the **new sense**) if

\[
\sup_{v \in S_\delta} \| R(\delta)g_\delta - v \| \leq \eta(\delta) \to 0 \text{ as } \delta \to 0.
\]

(1.2)

There is a crucial difference between our definition (1.2) and the standard definition (1):

- In (1) \( u \) is fixed, while in (1.2) \( v \) is any element of \( S_\delta \) and the supremum, over all such \( v \), of the norm in (1.2) must go to zero as \( \delta \to 0 \).

The new definition is more realistic and fits more computational needs because not only the solution \( u \) to (1.1) satisfies the inequality \( \| A(u) - g_\delta \| \leq \delta \), but many \( v \) satisfy such an inequality \( \| Av - g_\delta \| \leq \delta, \ v \in \mathcal{K} \), and the data \( g_\delta \) may correspond, in fact, to any \( v \in S_\delta \), and not only to the solution of equation (1.1). Therefore it is more natural to use definition (1.2) than (1).

Our aim is to illustrate the practical difference in these two definitions by an example, and to construct regularizer in the sense (1.2) for problem (1.1) under the following assumptions:

**A1)** \( A : X \to Y \) is a closed, possibly nonlinear, injective map, \( g \in \mathcal{R}(A) \), and

**A2)** \( \phi : D(\phi) \to [0, \infty), \phi(u) > 0 \) if \( u \neq 0 \), domain \( D(\phi) \subseteq D(A) \), the set \( \mathcal{K} = \mathcal{K}_c := \{ v : \phi(v) \leq c \} \) is compact in \( X \) and contains a sequence \( v_n \to v \), and \( \phi(v) \leq \liminf_{n \to \infty} \phi(v_n) \).

The last inequality holds if \( \phi \) is lower semicontinuous. Any Hilbert space norm and norms in reflexive Banach spaces have this property.

Examples in which assumptions A1) and A2) are satisfied are numerous.

**Example 1.** \( A \) is a linear injective compact operator, \( g \in \mathcal{R}(A) \), \( \phi(v) \) is a norm on \( X_1 \subset X \), where \( X_1 \) is densely imbedded in \( X \), the embedding \( i : X_1 \to X \) is compact, and \( \phi(v) \) is lower semicontinuous.

**Example 2.** \( A \) is a nonlinear injective continuous operator \( g \in \mathcal{R}(A) \), \( A^{-1} \) is not continuous, \( \phi \) as in Example 1.

**Example 3.** \( A \) is linear, injective, densely defined, closed operator, \( g \in \mathcal{R}(A) \), \( A^{-1} \) is unbounded, \( \phi \) as in Example 1, \( X_1 \subseteq D(A) \).

In section 2 it is shown that a regularizer in the sense (1) may be not a regularizer in the sense (1.2). In section 3 a theoretical construction of a regularizer in the sense (1.2) is given.

### 2 Example: stable numerical differentiation.

Here we use the results from [3] - [10].
Consider stable numerical differentiation of noisy data. The problem is:

\[ Au := \int_0^x u(s) \, ds = g(x), \quad g(0) = 0, \quad 0 \leq x \leq 1. \]  \hspace{1cm} (2.1)

The data are: \( g_\delta \) and \( M_a \), where \( \|g_\delta - g\| \leq \delta \), the norm is \( L^\infty(0, 1) \) norm, and \( \|u\|_a \leq M_a \), \( a \geq 1 \). The norm

\[ \|u\|_a := \sup_{x \in [0,1], x \neq y} \frac{|u(x) - u(y)|}{|x - y|^a} + \sup_{0 \leq x \leq 1} |u(x)| \quad \text{if } 0 \leq a \leq 1, \]

\[ \|u\|_a := \sup_{0 \leq x \leq 1} (|u(x)| + |u'(x)|) + \sup_{x \in [0,1], x \neq y} \frac{|u'(x) - u'(y)|}{|x - y|^{a-1}}, \quad 1 < a \leq 2. \]

If \( a > 1 \), then we define

\[ R(\delta)g_\delta := \begin{cases} 
\frac{g_\delta(x) - g_\delta(x-h(\delta))}{h(\delta)}, & h(\delta) \leq x \leq 1 - h(\delta), \\
\frac{g_\delta(x) - g_\delta(x-h(\delta))}{h(\delta)}, & 0 \leq x < h(\delta), \\
\frac{g_\delta(x) - g_\delta(x-h(\delta))}{h(\delta)}, & 1 - h(\delta) < x \leq 1,
\end{cases} \]

where

\[ h(\delta) = c_a \delta^{\frac{1}{a}}, \]  \hspace{1cm} (2.3)

and \( c_a \) is a constant given explicitly (cf [1]).

We prove that (2.2) is a regularizer for (2.1) in the sense (1.2), and \( \mathcal{K} := \{v : \|v\|_a \leq M_a, \ a > 1\} \). In this example we do not use lower semicontinuity of the norm \( \phi(v) \) and do not define \( \phi \).

Let \( S_{\delta,a} := \{v : \|Av - g_\delta\| \leq \delta, \ \|v\|_a \leq M_a\} \). To prove that (2.2)-(2.3) is a regularizer in the sense (1.2) we use the estimate

\[ \sup_{v \in S_{\delta,a}} \|R(\delta)g_\delta - v\| \leq \sup_{v \in S_{\delta,a}} \{\|R(\delta)(g_\delta - Av)\| + \|R(\delta)Av - v\|\} \leq \frac{\delta}{h(\delta)} + M_nh^{a-1}(\delta) \leq c_a\delta^{1 - \frac{1}{a}} := \eta(\delta) \to 0 \ \text{as} \ \delta \to 0. \]  \hspace{1cm} (2.4)

Thus we have proved that (2.2)-(2.3) is a regularizer in the sense (1.2).

If \( a = 1 \), and \( M_1 < \infty \), then one can prove that there is no regularizer for problem (2.1) in the sense (1.2) even if the regularizer is sought in the set of all operators, including nonlinear ones. More precisely, it is proved in [2] (see also [4]) that

\[ \inf_{R(\delta)} \sup_{v \in S_{\delta,1}} \|R(\delta)g_\delta - v\| \geq c > 0, \]

where \( c > 0 \) is a constant independent of \( \delta \) and the infimum is taken over all operators \( R(\delta) \) acting from \( L^\infty(0, 1) \) into \( L^\infty(0, 1) \), including nonlinear ones. On the other hand, if \( a = 1 \) and \( M_1 < \infty \), then a regularizer in the sense (1.2) does exist, but the rate of convergence in (*) may be as slow as one wishes, if \( u(x) \) is chosen suitably [9], [10].
3 Construction of a regularizer in the sense (1.2)

Assuming A1) and A2) (see Section 1) throughout this Section, let us construct a regularizer for (1.1) in the sense (1.2). We use the ideas from [10]. Define $F_\delta(v) := ||Av - g_\delta|| + \delta \phi(v)$ and consider the minimization problem of finding the infimum $m(\delta)$ of the functional $F_\delta(v)$ on a set $S_\delta$, defined below:

$$F_\delta(v) = \inf := m(\delta), \quad v \in S_\delta := \{v : ||Av - g_\delta|| \leq \delta, \phi(v) \leq c\}, \quad (3.1)$$

so that $K = K_c := \{v : \phi(v) \leq c\}$. The constant $c > 0$ can be chosen arbitrary large and fixed at the beginning of the argument, and then one can choose a smaller constant $c_1$, specified below. Since $F_\delta(u) = \delta + \delta \phi(u) := c_1 \delta$, $c_1 := 1 + \phi(u)$, where $u$ solves (1.1), one concludes that

$$m(\delta) \leq c_1 \delta. \quad (3.2)$$

Let $v_j$ be a minimizing sequence, such that $F_\delta(v_j) \leq 2m(\delta)$. Then $\phi(v_j) \leq 2c_1$. By assumption A2), as $j \to \infty$, one has:

$$v_j \to v_\delta, \quad \phi(v_\delta) \leq 2c_1. \quad (3.3)$$

Take $\delta = \delta_m \to 0$ and denote $v_\delta_m := w_m$. Then (3.3) and assumption A2) imply existence of a subsequence, denoted again $w_m$, such that:

$$w_m \to w, \quad A(w_m) \to A(w), \quad ||A(w) - g|| = 0. \quad (3.4)$$

Thus $A(w) = g$ and, since $A$ is injective, $w = u$, where $u$ is the unique solution to (1.1).

Define now $R(\delta)g_\delta$ by the formula $R(\delta)g_\delta := v_\delta$.

**Theorem 3.1.** $R(\delta)$ is a regularizer for problem (1.1) in the sense (1.2).

**Proof.** Assume the contrary:

$$\sup_{v \in S_\delta} ||R(\delta)g_\delta - v|| = \sup_{v \in S_\delta} ||v_\delta - v|| \geq \gamma > 0, \quad (3.5)$$

where $\gamma > 0$ is a constant independent of $\delta$. Since $\phi(v_\delta) \leq 2c_1$ by (3.3), and $\phi(v) \leq c$, one can choose convergent in $X$ sequences $w_m := v_\delta_m \to \tilde{w}$, $\delta_m \to 0$, and $v_\delta \to \tilde{v}$, such that $||w_m - v_m|| \geq \frac{\gamma}{2}$, $||\tilde{w} - \tilde{v}|| \geq \frac{\gamma}{2}$, and $A(\tilde{w}) = g$, $A(\tilde{v}) = g$. Therefore, by the injectivity of $A$, $\tilde{w} = \tilde{v} = u$, and one gets a contradiction with the inequality $||\tilde{w} - \tilde{v}|| \geq \frac{\gamma}{2} > 0$. This contradiction proves Theorem 3.1.

Note that the conclusions $A(\tilde{w}) = g$ and $A(\tilde{v}) = g$ follow from the inequalities $||A(v_\delta) - g_\delta|| \leq \delta$ and $||A(v) - g_\delta|| \leq \delta$ after passing to the limit $\delta \to 0$, using assumption A2). \(\square\)

**Remark 3.2.** Our argument is closely related to a generalization of a classical result [7] which says that an injective and continuous map of a compactum in a Banach space has continuous inverse. The generalization of this result, given in [8] (Chapter 5, Section...
6. Lemma 2), says that the same conclusion holds if \( A \) is an injective and closed map. This generalization, in other words, claims that if \( A \) is an injective and closed map of a compactum \( K \) in a Banach space into a Banach space, then the modulus of continuity \( \omega(\delta) \) of the inverse operator \( A^{-1} \) on the set \( A(K) \) tends to zero:

\[
\sup_{\|Av-Aw\| \leq \delta, v,w \in K} \|v-w\| := \omega(\delta) \to 0 \text{ as } \delta \to 0.
\]

Therefore, in our proof of Theorem 3.1, one has \( \sup_{v \in S_\delta} \|v_\delta - v\| \to 0 \text{ as } \delta \to 0 \).

Indeed, \( v \in S_\delta \) and \( v_\delta \in S_\delta \), so \( \|A(v) - g_\delta\| \leq \delta \) and \( \|A(v_\delta) - g_\delta\| \leq \delta \). Thus \( \|A(v) - A(v_\delta)\| \leq 2\delta \). Since \( v_\delta \) and \( v \) belong to a compactum \( K_{c_1} := \{v : \phi(v) \leq 2c_1\} \), Theorem 3.1 follows from the property \( \omega(\delta) \to 0 \) as \( \delta \to 0 \).

**Remark 3.3.** We have assumed that \( A \) is injective, that is, equation (1.1) has at most one solution. This assumption can be relaxed: one may assume that \( u \) solves (1.1) and there is an \( r > 0 \), such that in the ball \( B(u,r) := \{v : \|v-u\| \leq r\} \) the solution \( u \) is unique, but globally (1.1) may have many solutions. Our arguments remain valid if the compactum \( K := \{v : \phi(v) \leq c, v \in B(u,r)\} \).

One may drop the injectivity of \( A \) assumption in A1) in Section 1. In this case (3.4) yields \( w \in U \), where \( U := \{w : A(w) = g\} \). Thus, \( \lim_{\delta \to 0} \rho(R(\delta)g_\delta, U) = 0 \), where \( \rho(w,U) \) is the distance from an element \( w \) to the set \( U \).

In applications, when a physical problem is reduced to equation (1.1), one wants to have a unique solution to (1.1). If the solution is non-unique, that is, \( U \) contains more than one element, then one wants to impose additional conditions which select a unique solution in the set \( U \), thus making the operator \( A \) injective.
