Abstract

Charmless three-body decays of $B$ mesons are studied using a simple model based on the framework of the factorization approach. Hadronic three-body decays receive both resonant and nonresonant contributions. Dominant nonresonant contributions to tree-dominated three-body decays arise from the $b \to u$ tree transition which can be evaluated using heavy meson chiral perturbation theory valid in the soft meson limit. For penguin-dominated decays, nonresonant signals come mainly from the penguin amplitude governed by the matrix elements of scalar densities $\langle M_1 M_2 | \bar{q}_1 q_2 | 0 \rangle$. We use the measurements of $B^0 \to K_S K_S K_S$ to constrain the nonresonant component of $\langle K \bar{K} | \bar{s} s | 0 \rangle$. The intermediate vector meson contributions to three-body decays are identified through the vector current, while the scalar meson resonances are mainly associated with the scalar density. While the calculated direct $CP$ violation in $B^- \to K^+ K^- K^-$ and $B^- \to \pi^+ \pi^- \pi^-$ decays agrees well with experiment in both magnitude and sign, the predicted $CP$ asymmetries in $B^- \to \pi^- K^+ K^-$ and $B^- \to K^- \pi^+ \pi^-$ have incorrect signs when confronted with experiment. It has been conjectured recently that a possible resolution to this $CP$ puzzle may rely on final-state rescattering of $\pi^+ \pi^-$ and $K^+ K^-$. Assuming a large strong phase associated with the matrix element $\langle K \pi | \bar{s} q | 0 \rangle$ arising from some sort of power corrections, we fit it to the data of $K^- \pi^+ \pi^-$ and find a correct sign for $\pi^- K^+ K^-$. We predict some testable $CP$ violation in $\overline{B}^0 \to K^+ K^- \pi^0$ and $K^+ K^- K_S$. In the low mass regions of the Dalitz plot, we find that the regional $CP$ violation is indeed largely enhanced with respect to the inclusive one, though it is still significantly below the data. In this work, strong phases arise from effective Wilson coefficients, propagators of resonances and the matrix element of scalar density $\langle M_1 M_2 | \bar{q}_1 q_2 | 0 \rangle$. 
Recently, LHCb has measured direct $CP$ violation in charmless three-body decays of $B$ mesons and found evidence of $CP$ asymmetries in $B^+ \rightarrow \pi^+\pi^+\pi^-$ ($4.9\sigma$), $B^+ \rightarrow K^+K^+K^-$ ($3.7\sigma$) and $B^+ \rightarrow K^+K^-\pi^+$ ($3.2\sigma$) and a $2.8\sigma$ signal of $CP$ violation in $B^+ \rightarrow K^+\pi^+\pi^-$ (see Table I). Direct $CP$ violation in two-body resonances in the Dalitz plot has been seen at $B$ factories. For example, both BaBar [4] and Belle [5] have claimed evidence of partial rate asymmetries in the channel $B^\pm \rightarrow \rho^0(770)K^\pm$ in the Dalitz-plot analysis of $B^\pm \rightarrow K^{\pm}\pi^{\mp}\pi^{\pm}$. The inclusive $CP$ asymmetry in three-body decays results from the interference of the two-body resonances and three-body nonresonant decays and through the tree-penguin interference. $CP$ asymmetries in certain local regions of the phase space are likely to be greater than the integrated inclusive ones. Indeed, LHCb has also observed large asymmetries in localized regions of phase space [1–3]. For example, \begin{equation}
A_{CP}^{\text{region}}(K^+K^-K^-) = -0.226 \pm 0.020 \pm 0.004 \pm 0.007
\end{equation}
for $m_{K^+K^-}^2 \text{ high} < 15 \text{ GeV}^2$ and $1.2 < m_{K^+K^-}^2 \text{ low} < 2.0 \text{ GeV}^2$, \begin{equation}
A_{CP}^{\text{region}}(K^-\pi^+\pi^-) = 0.678 \pm 0.078 \pm 0.032 \pm 0.007
\end{equation}
for $m_{K^-\pi^+}^2 \text{ high} < 15 \text{ GeV}^2$ and $0.08 < m_{\pi^+\pi^-}^2 \text{ low} < 0.66 \text{ GeV}^2$, \begin{equation}
A_{CP}^{\text{region}}(K^+K^-\pi^-) = -0.648 \pm 0.070 \pm 0.013 \pm 0.007
\end{equation}
for $m_{K^+K^-}^2 < 1.5 \text{ GeV}^2$, and \begin{equation}
A_{CP}^{\text{region}}(\pi^+\pi^-\pi^-) = 0.584 \pm 0.082 \pm 0.027 \pm 0.007
\end{equation}
for $m_{\pi^-\pi^-}^2 \text{ low} < 0.4 \text{ GeV}^2$ and $m_{\pi^+\pi^-}^2 \text{ high} > 15 \text{ GeV}^2$. Hence, significant signatures of $CP$ violation were found in the above-mentioned low mass regions devoid of most of the known resonances.

Three-body decays of heavy mesons are more complicated than the two-body case as they receive both resonant and nonresonant contributions. The analysis of these decays using the Dalitz plot technique enables one to study the properties of various vector and scalar resonances. Indeed, most of the quasi-two-$B$ decays are extracted from the Dalitz-plot analysis of three-body ones. Three-body hadronic $B$ decays involving a vector meson or a charmed meson in the final state also have been observed at $B$ factories. In this work we shall focus on charmless $B$ decays into three pseudoscalar mesons.

It is known that the nonresonant signal in charm decays is small, less than 10% [7]. In the past years, many of the charmless $B$ to three-body decay modes have been measured at $B$ factories and studied using the Dalitz-plot analysis. The measured fractions and the corresponding branching fractions of nonresonant components for some of three-body $B$ decay modes are summarized in Table II. We see that the nonresonant fraction is about $\sim (70 - 100\%)$ in $B \rightarrow KKK$ decays, $\sim (17 - 40\%)$ in $B \rightarrow K\pi\pi$ decays, and $\sim 35\%$ in the $B \rightarrow \pi\pi\pi$ decay. Hence, the nonresonant three-body decays play an essential role in penguin-dominated $B$ decays. While this is striking in view of the rather small nonresonant background in three-body charm decays, it is not entirely unexpected because the energy release scale in weak $B$ decays is of order 5 GeV, whereas the major resonances lie in the energy region of 0.77 to 1.6 GeV. Consequently, it is likely that three-body $B$ decays...
decays may receive sizable nonresonant contributions. It is important to understand and identify the underlying mechanism for nonresonant decays.

Consider the nonresonant contributions to the three-body $B$ decay $B \to P_1 P_2 P_3$. Under the factorization hypothesis, one of the nonresonant components arises from the transitions $B \to P_1 P_2$ with an emission of $P_3$. The nonresonant background in charmless three-body $B$ decays due to the transition $B \to P_1 P_2$ has been studied extensively [22–27] based on heavy meson chiral perturbation theory (HMChPT) [28–30]. However, the predicted rates of nonresonant decays due to $B \to P_1 P_2$ transition alone already exceed the measured total branching fractions for the tree-dominated modes e.g. $\pi^- \pi^+ \pi^-$ and $\pi^- K^+ K^-$. For example, the branching fraction of the nonresonant rate of $B^- \to \pi^+ \pi^- \pi^-$ estimated using HMChPT is found to be of order $75 \times 10^{-6}$, which is even larger than the total branching fraction of order $15 \times 10^{-6}$ (see Table I). The issue has to do with the applicability of HMChPT. When it is applied to three-body decays, two of the final-state pseudoscalars have to be soft. If the soft meson result is assumed to be the same in the whole Dalitz plot, the decay rate will be greatly overestimated. To overcome this issue, we have proposed in [31] to parameterize the momentum dependence of nonresonant amplitudes induced by $b \to u$ transition in an exponential form so that the HMChPT results are recovered in the soft pseudoscalar meson limit.

However, the nonresonant background in $B \to P_1 P_2$ transition does not suffice to account for the experimental observation that nonresonant contributions dominate in the penguin-dominated decays $B \to KKK$ and $B \to K\pi\pi$. As we have emphasized in [31], this implies that the nonresonant amplitude is also penguin dominated and governed by the matrix elements, e.g., $\langle K\overline{K}|\overline{s}s|0\rangle$ and $\langle K\pi|\overline{s}q|0\rangle$. That is, the matrix element of scalar density should have a large nonresonant component. In [31] we have used the $B^0 \to K_S K_S K_S$ mode in conjunction with the mass spectrum in $\overline{B} \to K^+ K^- K^0$ to fix the nonresonant contribution to $\langle K\overline{K}|\overline{s}s|0\rangle$.

Besides the nonresonant background, it is necessary to study resonant contributions to three-

body decays. The intermediate vector meson contributions to three-body decays are identified through the vector current, while the scalar meson resonances are mainly associated with the scalar density. They can also contribute to the three-body matrix element $\langle P_1P_2|J_\mu|B\rangle$. Resonant effects are conventionally described in terms of the usual Breit-Wigner formalism. In this manner we are
able to identify the relevant resonances which contribute to the three-body decays of interest and compute the rates of $B \to VP$ and $B \to SP$. In conjunction with the nonresonant contribution, we are ready to calculate the total rates for three-body decays.

There are several competing approaches for describing charmless hadronic two-body decays of $B$ mesons, such as QCD factorization (QCDF) [32], pQCD [33] and soft-collinear effective theory [34]. Measurements of $CP$ asymmetries will allow us to discriminate between different models and improve the approach. For example, in the heavy quark limit, the predicted $CP$ asymmetries for the penguin-dominated modes $B^0 \to K^-\pi^+$, $K^+\pi^+$, $K^-\rho^+$, $B^0_\rho \to K^+\pi^-$ have incorrect signs when confronted with experiment [35, 36]. In the approach of QCDF, their signs can be flipped into the right direction by considering $1/m_b$ power corrections from penguin annihilation. Therefore, even an information on the sign of $CP$ asymmetries will be very valuable.

The recent LHCb measurements of inclusive and local direct $CP$ asymmetries in charmless $B \to P_1 P_2 P_3$ decays [1, 3] provide a new testground of the factorization approach. Let’s first check the signs of $CP$ violation. The observed negative relative sign of $CP$ asymmetries between $B^- \to \pi^-\pi^+\pi^-$ and $B^- \to K^-K^+K^-$ and between $B^- \to K^-\pi^+\pi^-$ and $B^- \to \pi^-K^+K^-$ is in accordance with what expected from U-spin symmetry which enables us to relate the $\Delta S = 0$ amplitude to the $\Delta S = 1$ one. However, symmetry arguments alone do not tell us the relative sign of $CP$ asymmetries between $\pi^-\pi^+\pi^-$ and $\pi^-K^+K^-$ and between $K^-\pi^+\pi^-$ and $K^-K^+K^-$. Based on a realistic model calculation we find positive relative signs which are in contradiction to the LHCb experiment. How to resolve this $CP$ enigma becomes a very important issue in the study of hadronic 3-body decays. The LHCb observation of the correlation of the $CP$ violation between the decays, $A_{CP}(\pi^-\pi^+\pi^-) \approx -A_{CP}(\pi^-K^+K^-)$ and $A_{CP}(K^-\pi^+\pi^-) \approx -A_{CP}(K^-K^+K^-)$, has led to the conjecture that $\pi^+\pi^- \leftrightarrow K^+K^-$ rescattering may play an important role in the generation of the strong phase difference needed for such a violation to occur.

In this work we shall follow the framework of [31] to update the analysis of three-body decays and explore inclusive and regional $CP$ violation in detail. We take the factorization approximation as a working hypothesis rather than a first-principles starting point as factorization has not been proved for three-body $B$ decays. Therefore, we shall work in the phenomenological factorization model rather than in the established theories such as QCDF, pQCD or soft-collinear effective theory.

For $CP$ violation, we will focus on direct $CP$ asymmetry and will not discuss mixing-induced $CP$ violation in, for example, $B^0 \to K^+K^-K_S$ and $K_SK_SK_S$. This topic has been discussed in [31, 39].

The layout of the present paper is as follows. We shall first discuss the decay $B \to \pi\pi\pi$ in Sec. II in order to fix the parameter for describing the nonresonant background at the tree level. We discuss this mode in detail to set up the framework for studying resonant and nonresonant contributions. Then in Sec. III we proceed to $B \to KK\pi$ decays to emphasize the importance of nonresonant penguin contributions to penguin-dominated modes. The three-body channels $B \to K\pi\pi$ and $B \to KK\pi$ are discussed in Secs. IV and V, respectively. In Sec. VI, we determine the rates for $B \to VP$ and $B \to SP$ and compare our results with the approach of QCD factorization. Inclusive

---

1 For the study of $B \to PPP$ decays in different approaches, the reader is referred to [37, 38].
and localized $CP$ asymmetries are addressed in Sec. VII. Sec. VIII contains our conclusions. Some of the input parameters used in this work are collected in Appendix A. Factorizable amplitudes for some of $B \to PPP$ decays not discussed previously in $[31]$ are shown in Appendix B.

II. $B \to \pi\pi\pi$ DECAYS

For three-body $B$ decays, the $b \to sq \bar{q}$ penguin transitions contribute to the final states with odd number of kaons, namely, $KKK$ and $K\pi\pi$, while $b \to uq \bar{q}$ tree and $b \to dq \bar{q}$ penguin transitions contribute to final states with even number of kaons, e.g. $KK\pi$ and $\pi\pi\pi$. We shall discuss the decay $B \to \pi\pi\pi$ first in order to fix the parameter needed for describing the nonresonant background at the tree level and then $B \to KKK$ to fix the unknown parameter for the nonresonant penguin contribution. Finally we proceed to discuss $B \to K\pi\pi$ and $B \to K\pi\pi$ channels.

Under the factorization hypothesis, the decay amplitudes are given by

$$\langle P_1 P_2 P_3 | H_{\text{eff}} | B \rangle = \frac{G_F}{\sqrt{2}} \sum_{p=\text{u.c.}} \lambda_{p}^{(r)} \langle P_1 P_2 P_3 | T_p^{(r)} | B \rangle,$$

where $\lambda_{p}^{(r)} \equiv V_{pb} V_{pr}^\ast$ with $r = d, s$. For $KKK$ and $K\pi\pi$ modes, $r = s$ and for $KK\pi$ and $\pi\pi\pi$ channels, $r = d$. The Hamiltonian $T_p^{(r)}$ has the expression $[32]$

$$T_p^{(r)} = a_1 \delta_{pu}(\bar{u}b)_{V-A} \otimes (\bar{r}u)_{V-A} + a_2 \delta_{pu}(\bar{r}b)_{V-A} \otimes (\bar{u}u)_{V-A} + a_3 (\bar{r}b)_{V-A} \otimes \sum_q (\bar{q}q)_{V-A}$$

$$+ a_4 \sum_q (\bar{q}b)_{V-A} \otimes (\bar{r}q)_{V-A} + a_5 (\bar{r}b)_{V-A} \otimes \sum_q (\bar{q}q)_{V+A}$$

$$- 2a_6 \sum_q (\bar{q}b)_{S-P} \otimes (\bar{r}q)_{S+P} + a_7 (\bar{r}b)_{V-A} \otimes \sum_q \frac{3}{2} e_q (\bar{q}q)_{V+A}$$

$$- 2a_8 \sum_q (\bar{q}b)_{S-P} \otimes \frac{3}{2} e_q (\bar{r}q)_{S+P} + a_9 (\bar{r}b)_{V-A} \otimes \sum_q \frac{3}{2} e_q (\bar{q}q)_{V-A}$$

$$+ a_{10} \sum_q (\bar{q}b)_{V-A} \otimes \frac{3}{2} e_q (\bar{r}q)_{V-A},$$

with $(\bar{q}q')_{V\pm A} \equiv \bar{q} \gamma_\mu (1 \pm \gamma_5) q'$, $(\bar{q}q')_{S\pm P} \equiv \bar{q} (1 \pm \gamma_5) q'$ and a summation over $q = u, d, s$ being implied. For the effective Wilson coefficients, we shall follow $[31]$ to use

$$a_1 \approx 0.99 \pm 0.037i, \quad a_2 \approx 0.19 - 0.11i, \quad a_3 \approx -0.002 + 0.004i, \quad a_5 \approx 0.0054 - 0.005i,$$

$$a_4 \approx -0.03 - 0.02i, \quad a_4' \approx -0.04 - 0.008i, \quad a_6 \approx -0.06 - 0.02i, \quad a_6' \approx -0.06 - 0.006i,$$

$$a_7 \approx 0.54 \times 10^{-4}i, \quad a_8 \approx (4.5 - 0.5i) \times 10^{-4}, \quad a_8' \approx (4.4 - 0.3i) \times 10^{-4},$$

$$a_9 \approx -0.010 - 0.0002i, \quad a_9' \approx (-58.3 + 86.1i) \times 10^{-5}, \quad a_{10} \approx (-60.3 + 88.8i) \times 10^{-5},$$

for typical $a_3$ at the renormalization scale $\mu = m_b/2 = 2.1 \text{ GeV}$. The strong phases of the effective Wilson coefficients arise from vertex corrections and penguin contractions calculated in the QCD factorization approach $[32]$. 

A. $B^- \to \pi^+ \pi^- \pi^-$ decay

The factorizable tree-dominated $B^- \to \pi^+ \pi^- \pi^-$ decay reads

$$
\langle \pi^+ \pi^- \pi^- | T_B | B^- \rangle = \langle \pi^+ \pi^- | (\bar{u}b)_V - A | B^- \rangle \langle \pi^- | (\bar{d}u)_V - A | 0 \rangle \left[ a_1 \delta_{pu} + a_2^0 + a_0^p - (a_0^u + a_0^d) r_\pi \right]
+ \langle \pi^- | (\bar{d}b)_V - A | B^- \rangle \langle \pi^- | (\bar{u}u)_V - A | 0 \rangle \left[ a_2 \delta_{pu} + a_3 + a_5 + a_7 + a_9 \right]
+ \langle \pi^- | (\bar{d}b)_V - A | B^- \rangle \langle \pi^- | (\bar{d}d)_V - A | 0 \rangle \left[ a_3 + a_4^0 + a_5 - \frac{1}{2}(a_7 + a_9 + a_1^p) \right]
+ \langle \pi^- | (\bar{d}b)_V | B^- \rangle \langle \pi^- | | \bar{d}d | (0) | -2a_0^p + a_2^p \rangle
+ \langle \pi^- - \pi^- | (\bar{u}u)_V - A | 0 \rangle \langle \bar{u} (u | B^- \rangle \langle \bar{u} | V - A | 0 \rangle \langle \pi^- | \bar{u} | d 1 + \gamma_5 u | (0) | \bar{u} | \gamma_5 b | B^- \rangle (2a_0^p + 2a_1^p),
(2.4)
$$

where $r_\pi^2(\mu) = 2\frac{m_\pi^2}{m_3(\mu)(m_3(\mu) - m_u(\mu))}$. Since there are two identical $\pi^-$ mesons in this decay, one should take into account the identical particle effects. For example,

$$
\langle \pi^+ \pi^- | (\bar{u}b)_V - A | B^- \rangle \langle \pi^- | (\bar{d}u)_V - A | 0 \rangle = \langle \pi^+ (p_1) | \pi^- (p_2) | (\bar{u}b)_V - A | B^- \rangle \langle \pi^- | p_3 \rangle (\bar{u}d)_V - A | 0 \rangle
+ \langle \pi^+ (p_1) | \pi^- | (\bar{u}b)_V - A | B^- \rangle \langle \pi^- | p_2 \rangle (\bar{u}d)_V - A | 0 \rangle,
(2.5)
$$

and a factor of $\frac{1}{2}$ should be put in the decay rate. Note that $\langle \pi^+ \pi^- | (\bar{d}d)_V - A | 0 \rangle = -\langle \pi^+ \pi^- | (\bar{u}u)_V - A | 0 \rangle$ due to isospin symmetry. The matrix element $\langle \pi^+ \pi^- | (\bar{s}s)_V - A | 0 \rangle$ is suppressed by the OZI rule.

Under the factorization approach, the $B^- \to \pi^+ \pi^- \pi^-$ decay amplitude consists of three distinct factorizable terms: (i) the current-induced process with a meson emission, $\langle B^- \to \pi^+ \pi^- \rangle \times (0 \to \pi^-)$, (ii) the transition process, $\langle B^- \to \pi^- \rangle \times (0 \to \pi^+ \pi^-)$, and (iii) the annihilation process $\langle B^- \to 0 \rangle \times (0 \to \pi^+ \pi^- \pi^-)$, where $\langle A \to B \rangle$ denotes a $A \to B$ transition matrix element. We shall consider the nonresonant background and resonant contributions separately.

1. Nonresonant background

For the current-induced process, the three-body matrix element $\langle \pi^+ \pi^- | (\bar{u}b)_V - A | B^- \rangle$ has the general expression \[40\]

$$
\langle \pi^+ (p_1) | \pi^- (p_2) | (\bar{u}b)_V - A | B^- \rangle = i r (p_B - p_1 - p_2) | \mu + i \omega_+ (p_2 + p_1) | \mu + i \omega_- (p_2 - p_1) \mu
+ h \epsilon_{\mu \nu \alpha \beta} \rho_{\alpha}^B (p_2 + p_1) \alpha (p_2 - p_1) \beta.
(2.6)
$$

The form factors $r$, $\omega_\pm$, and $h$ can be evaluated in the framework of heavy meson chiral perturbation theory (HMChPT) \[40\]. However, this will lead to decay rates that are too large, in disagreement with experiment \[1\]. The heavy meson chiral Lagrangian given in \[28, 30\] is needed to compute the strong $B^* B^\prime P$, $B^* B^\prime P$ and $BB PP$ vertices. The results for the form factors read \[23, 40\]

$$
\omega_+ = - \frac{g}{f_{\pi}} \frac{f_{B^*} m_{B^*} \sqrt{m_B m_{B^*}}}{s_{23} - m_{B^*}^2} \left[ 1 - \frac{(p_B - p_1) \cdot p_1}{m_B^2} \right] + \frac{f_B}{2 f_{\pi}^2},
$$

\[7\]
\[
\omega_\pi = \frac{g}{f_\pi} \sqrt{m_B m_{\pi^+}} \left[ 1 + \frac{(p_B - p_1) \cdot p_1}{m_{B^*}^2} \right],
\]
\[
\rho = \frac{f_B}{f_\pi} - \frac{f_B}{f_\pi} \frac{p_B \cdot (p_2 - p_1)}{(p_B - p_1 - p_2)^2 - m_B^2} + \frac{2g f_B}{f_\pi} \frac{m_B (p_B - p_1) \cdot p_1}{m_{B^*}^2} - \frac{4g^2 f_B}{f_\pi^2} \frac{m_B m_{B^*}^2}{(p_B - p_1 - p_2)^2 - m_B^2} \frac{p_1 \cdot p_2 - p_1 \cdot (p_B - p_1) p_2 \cdot (p_B - p_1) / m_{B^*}^2}{s_{23} - m_B^2},
\]

where \( s_{ij} \equiv (p_i + p_j)^2, f_\pi = 132 \text{ MeV} \), \( g \) is a heavy-flavor independent strong coupling which can be extracted from the CLEO measurement of the \( D^{**} \) decay width, \(|g| = 0.59 \pm 0.01 \pm 0.07 \) \cite{ref:CLEO}. We shall follow \cite{ref:HMChPT} to fix its sign to be negative. It follows that

\[
A_{\text{current-ind}}^{\text{HMChPT}} = \langle \pi^- (p_3) \langle \bar{s}u \rangle_{V-A} | 0 \rangle \langle \pi^+ (p_1) \pi^- (p_2) \rangle | (\bar{u}b)_{V-A} | B^- \rangle = -\frac{f_\pi}{2} \left[ 2m_2^2 r + (m_B^2 - s_{12} - m_3^2) \omega_+ + (s_{23} - s_{13} - m_2^2 + m_1^2) \omega_- \right].
\]

However, as pointed out before, the predicted nonresonant rates based on HMChPT are unexpectedly too large for tree-dominated decays. For example, the branching fraction of nonresonant \( B^- \to \pi^+ \pi^- \pi^- \) is found to be of order \( 75 \times 10^{-6} \), which is one order of magnitude larger than the BaBar result of \( \sim 5.3 \times 10^{-6} \) (see Table \ref{table:decay_rates}). The issue has to do with the applicability of HMChPT. In order to apply this approach, two of the final-state pseudoscalars in \( B \to P_1 P_2 \) transition have to be soft. The momentum of the soft pseudoscalar should be smaller than the chiral symmetry breaking scale of order 1 GeV. For three-body charmless \( B \) decays, the available phase space where chiral perturbation theory is applicable is only a small fraction of the whole Dalitz plot. Therefore, it is not justified to apply chiral and heavy quark symmetries to a certain kinematic region and then generalize it to the region beyond its validity. If the soft meson result is assumed to be the same in the whole Dalitz plot, the decay rate will be greatly overestimated. Following \cite{ref:Cheng}, we shall assume the momentum dependence of nonresonant amplitudes in an exponential form, namely,

\[
A_{\text{current-ind}} = A_{\text{current-ind}}^{\text{HMChPT}} e^{-\alpha_{NR} p_B \cdot (p_1 + p_2)} e^{i\phi_{12}},
\]

so that the HMChPT results are recovered in the soft meson limit \( p_1, p_2 \to 0 \). That is, the nonresonant amplitude in the soft meson region is described by HMChPT, but its energy dependence beyond the chiral limit is governed by the exponential term \( e^{-\alpha_{NR} p_B \cdot (p_1 + p_2)} \). In what follows, we shall use the tree-dominated \( B^- \to \pi^+ \pi^- \pi^- \) decay data to fix the unknown parameter \( \alpha_{NR} \). Besides the nonresonant contribution from the current-induced process, the matrix elements \( \langle \pi^+ \pi^- | \bar{q} \gamma_\mu q | 0 \rangle \) and \( \langle \pi^+ \pi^- | \bar{d} d | 0 \rangle \) also receive nonresonant contributions. In principle, the weak vector form factor of the former matrix element can be related to the charged pion electromagnetic (e.m.) form factors. However, unlike the kaon case which will be discussed below, the time-like e.m. form factors of the pions are not well measured enough allowing us to determine the nonresonant parts. Therefore, we shall only consider the resonant contribution to \( \langle \pi^+ \pi^- | \bar{q} \gamma_\mu q | 0 \rangle \). As for the matrix element \( \langle \pi^+ \pi^- | \bar{d} d | 0 \rangle \), it can be related to \( \langle K^+ K^- | \bar{s} s | 0 \rangle \) to be discussed below via SU(3) flavor symmetry. Nevertheless, it is suppressed by the smallness of the penguin Wilson coefficients \( a_6 \) and \( a_8 \). Therefore, the nonresonant component of \( B^- \to \pi^+ \pi^- \pi^- \) is predominated by the current-induced process, and its measurement provides an ideal place to constrain the parameter \( \alpha_{NR} \), which turns out to be

\[
\alpha_{NR} = 0.081^{+0.015}_{-0.009} \text{ GeV}^{-2}.
\]
This is very close to the naive expectation of $\alpha_{NR} \sim O(1/(2m_B^2))$ based on the dimensional argument. The phase $\phi_{12}$ of the nonresonant amplitude in the $(\pi^+\pi^-)$ system will be set to zero for simplicity.

2. Resonant contributions

In general, vector meson and scalar resonances contribute to the two-body matrix elements $\langle P_1P_2|V_\mu|0\rangle$ and $\langle P_1P_2|S|0\rangle$, respectively. They can also contribute to the three-body matrix element $\langle P_1P_2|J_\mu|B\rangle$. Resonant effects are described in terms of the usual Breit-Wigner formalism. More precisely,

$$\langle \pi^+(p_1)\pi^-(p_2)|\langle \bar{u}b\rangle_{V^-A}|B^-\rangle^R = \sum_i \frac{g_{V_i\to\pi^+\pi^-}^{S_i}}{s_{12} - m_{V_i}^2 + i m_{V_i} \Gamma_{V_i}} \sum_{\text{pol}} \epsilon^* \cdot (p_1 - p_2) \langle V_i|\langle \bar{u}b\rangle_{V^-A}|B^-\rangle,$$

$$\langle \pi^+(p_1)\pi^-(p_2)|\bar{q}\gamma_\mu q|0\rangle^R = \sum_i \frac{g_{V_i\to\pi^+\pi^-}^{S_i}}{s_{12} - m_{S_i}^2 + i m_{S_i} \Gamma_{S_i}} \langle S_i|\langle \bar{u}b\rangle_{V^-A}|B^-\rangle,$$

$$\langle \pi^+(p_1)\pi^-(p_2)|\bar{q}\gamma_\mu q|0\rangle^R = \sum_i \frac{g_{V_i\to\pi^+\pi^-}^{S_i}}{s_{12} - m_{V_i}^2 + i m_{V_i} \Gamma_{V_i}} \sum_{\text{pol}} \epsilon^* \cdot (p_1 - p_2) \langle V_i|\bar{q}\gamma_\mu q|0\rangle,$$

$$\langle \pi^+\pi^-|\bar{d}d|0\rangle^R = -\sum_i \frac{g_{V_i\to\pi^+\pi^-}^{S_i}}{s_{12} - m_{S_i}^2 + i m_{S_i} \Gamma_{S_i}} \langle S_i|\bar{d}d|0\rangle.$$

Using the decay constants defined by

$$\langle S|q\bar{q}q|0\rangle = m_S f_S, \quad \langle P(p)|\bar{q}\gamma_\mu q|0\rangle = -if_{P\mu}, \quad \langle V(p)|\bar{q}\gamma_\mu q|0\rangle = f_V m_V \epsilon_\mu^*,$$

and form factors defined by

$$\langle P'(p')|V_\mu|B(p)\rangle = \left((p + p')_\mu - \frac{m_B^2 - m_{V'}^2}{q^2} q_\mu\right) F_1^{BP}(q^2) + \frac{m_B^2 - m_{V'}^2}{q^2} q_\mu F_0^{BP}(q^2),$$

The two-body matrix element $\langle P_1P_2|V_\mu|0\rangle$ sometimes can also receive contributions from scalar resonances. For example, both $K^*$ and $K_0^*(1430)$ contribute to the matrix element $\langle K^-\pi^+|(sd)_{V^-A}|0\rangle$, see Eq. (2.12).

We follow [43] for the $B \to P$ and $B \to V$ transition form factors. Form factors for $B \to S$ transitions are defined in [44].
\[
\langle S(p')|A_\mu|B(p)\rangle = -i \left[ \left( p + p' \right)_\mu - \frac{m_B^2 - m_S^2}{q^2} q_\mu \right] F_1^{BS}(q^2) + \frac{m_B^2 - m_S^2}{q^2} q_\mu F_0^{BS}(q^2) \right],
\]

\[
\langle V(p', \varepsilon)|V_\mu|B(p)\rangle = \frac{2}{m_B + m_V} \varepsilon_{\mu\nu\alpha\beta} \bar{p}^\nu p^\beta V(q^2),
\]

\[
\langle V(p', \varepsilon)|A_\mu|B(p)\rangle = i \left[ \left( m_B + m_V \right) \varepsilon^*_{\mu} A_1^{BV}(q^2) - \frac{\varepsilon^* \cdot p}{m_B + m_V} (p + p')_\mu A_2^{BV}(q^2) \right.
- 2m_V \frac{\varepsilon^* \cdot p}{q^2} q_\mu [A_3^{BV}(q^2) - A_0^{BV}(q^2)],
\]

\[\text{(2.14)}\]

where \( P_\mu = (p + p')_\mu, \quad q_\mu = (p - p')_\mu, \quad A_3^{BV}(0) = A_0^{BV}(0), \quad A_3^{BV}(q^2) = \frac{m_B + m_V}{2m_V} A_1^{BV}(q^2) - \frac{m_B - m_V}{2m_V} A_2^{BV}(q^2), \]

we are led to

\[
\langle \pi^+(p_1)\pi^-(p_2)|\bar{u}b\rangle_{V-A}|B^-\rangle^R \langle \pi^-(p_3)|\bar{d}u\rangle_{V-A}|0\rangle

= - \sum_i \frac{f_\pi}{2\sqrt{2}} \frac{g_{\rho^i \to \pi^+ \pi^-}}{s_{12} - m_\rho^2 + i m_\rho \Gamma_\rho_i (s_{13} - s_{23})} \left[ (m_B + m_\rho) A_1^{B\rho_i}(q^2) \right.

- \frac{A_2^{B\rho_i}(q^2)}{m_B + m_\rho} (m_B^2 - s_{12}) - 2m_\rho [A_3^{B\rho_i}(q^2) - A_0^{B\rho_i}(q^2)]

\left. - \sum_i \frac{f_\pi}{s_{12} - m_{f_0i}^2 + i m_{f_0i} \Gamma_{f_0i}} (m_B^2 - s_{12}) F_0^{Bf_0}(q^2) \right],
\]

\[\text{(2.15)}\]

with \( q^2 = (p_B - p_1 - p_2)^2 = p_3^2 \), and

\[
\langle \pi^+(p_1)\pi^-(p_2)|\bar{u}\gamma_{\mu} u\rangle_{V-A}|0\rangle^R

= - \frac{1}{\sqrt{2}} \sum_i \frac{m_{\rho_i} f_{\rho_i} g_{\rho^i \to \pi^+ \pi^-}}{s_{12} - m_\rho^2 + i m_\rho \Gamma_\rho_i} (p_1 - p_2)_\mu,
\]

\[
\langle \pi^+(p_1)\pi^-(p_2)|\bar{d}d\rangle_{V-A}|0\rangle^R

= - \sum_i \frac{m_{f_{0i}} f_{d_{0i}} g_{f_0 \to \pi^+ \pi^-}}{s_{12} - m_{f_0i}^2 + i m_{f_0i} \Gamma_{f_0i}},
\]

\[\text{(2.17)}\]

the scalar decay constant \( f_{d_{0i}}^0 \) is defined by \( \langle f_{0i}|\bar{q}q\rangle_{V-A}|0\rangle = m_{f_{0i}} f_{d_{0i}}^0, \quad g_{f_0 \to \pi^+ \pi^-} \) is the \( f_{0i} \to \pi^+ \pi^- \) strong coupling. Hence, the relevant transition amplitudes are

\[
\langle \pi^+(p_1)\pi^-(p_2)|\bar{u}u\rangle_{V-A}|0\rangle^R \langle \pi^-(p_3)|\bar{d}d\rangle_{V-A}|B^-\rangle = -F_1^{B\pi}(s_{12}) \Gamma_R \pi^+(s_{12}) (s_{13} - s_{23}),
\]

\[
\langle \pi^+(p_1)\pi^-(p_2)|\bar{d}d\rangle_{V-A}|0\rangle^R \langle \pi^-|\bar{d}d\rangle_{V-A}|B^-\rangle

= -\frac{m_B^2 - m_\rho^2}{m_b - m_d} F_0^{B\pi}(s_{12}) \sum_i \frac{m_{f_{0i}} f_{j_{0i}} g_{f_0 \to \pi^+ \pi^-}}{s_{12} - m_{f_0i}^2 + i m_{f_0i} \Gamma_{f_0i}},
\]

\[\text{(2.18)}\]

with

\[
F_R^{\pi^+ \pi^-}(s) = \frac{1}{\sqrt{2}} \sum_i \frac{m_{\rho_i} f_{\rho_i} g_{\rho^i \to \pi^+ \pi^-}}{s - m_\rho^2 + i m_\rho \Gamma_\rho_i}.
\]

\[\text{(2.19)}\]

3. Numerical results

The strong coupling constants such as \( g_{\rho(770) \to \pi^+ \pi^-} \) and \( g_{f_0(980) \to \pi^+ \pi^-} \) are determined from the measured partial widths through the relations

\[
\Gamma_{S \to P_1 P_2} = \frac{p_c}{8\pi m_S^2} g_S^{P_1 P_2}, \quad \Gamma_{V \to P_1 P_2} = \frac{2}{3} \frac{p^3}{4\pi m_V^2} g_V^{P_1 P_2},
\]

\[\text{(2.20)}\]
TABLE III: Branching fractions (in units of $10^{-6}$) of resonant and nonresonant (NR) contributions to $B^- \rightarrow \pi^+\pi^-\pi^-$. The nonresonant background is used as an input to fix the parameter $\alpha_{NR}$ defined in Eq. (2.9). Theoretical errors correspond to the uncertainties in (i) $\alpha_{NR}$, (ii) $F_{0}^{B\pi}$, $\sigma_{NR}$ and $m_{s}(\mu) = (90 \pm 20)$MeV at $\mu = 2.1$ GeV, and (iii) $\gamma = (69.7^{+1.3}_{-2.8})^{\circ}$. Experimental results are taken from Table I.

| Decay mode $\rightarrow \pi^{+}\pi^{-}\pi^{-}$ | BaBar $[8]$ | Theory |
|-----------------------------------------------|-------------|--------|
| $\rho^{0}\pi^{-}$                             | $8.1 \pm 0.7 \pm 1.2^{+0.4}_{-1.1}$ | $6.7^{+0.0+0.4+0.1}_{-0.0-0.4-0.1}$ |
| $\rho^{0}(1450)\pi^{-}$                       | $1.4 \pm 0.4 \pm 0.4^{+0.3}_{-0.7}$ |                                    |
| $f_{0}(1370)\pi^{-}$                           | $2.9 \pm 0.5 \pm 0.5^{+0.7}_{-0.5}$ | $1.6^{+0.0+0.4+0.0}_{-0.0-0.4-0.0}$ |
| $f_{0}(980)\pi^{-}$                            | $< 1.5$     | $0.2^{+0.0+0.3+0.0}_{-0.0-0.3-0.0}$ |
| NR                                            | $5.3 \pm 0.7 \pm 0.6^{+1.1}_{-0.5}$ | input |
| Total                                         | $15.2 \pm 0.6 \pm 1.2^{+0.4}_{-0.3}$ | $16.1^{+1.9+1.0+0.5}_{-2.3-0.8-0.2}$ |

for scalar and vector mesons, respectively, where $p_{c}$ is the c.m. momentum. The numerical results are

$$g^{\rho(770)\rightarrow \pi^{+}\pi^{-}} = 6.0, \quad \quad \quad g^{K^{+}(892)\rightarrow K^{+}\pi^{-}} = 4.59,$$

$$g^{f_{0}(980)\rightarrow \pi^{+}\pi^{-}} = 1.33^{+0.29}_{-0.26} \text{GeV}, \quad \quad g^{K_{0}^{+}(1430)\rightarrow K^{+}\pi^{-}} = 3.84 \text{GeV}.$$ (2.21)

Note that the neutral $\rho$ meson cannot decay into $\pi^{0}\pi^{0}$ owing to isospin invariance. In determining the coupling of $f_{0} \rightarrow \pi^{+}\pi^{-}$, we have used the partial width

$$\Gamma(f_{0}(980) \rightarrow \pi^{+}\pi^{-}) = (34.2^{+13.9+8.8}_{-11.8-2.5}) \text{ MeV}$$ (2.22)

measured by Belle $[45]$. In this work, we shall specifically use $g^{f_{0}(980)\rightarrow \pi^{+}\pi^{-}} = 1.18 \text{GeV}$ to have a better description of $B \rightarrow f_{0}(980)K$ channels in $B \rightarrow K\pi\pi$ decays.

The calculated branching fractions of resonant and nonresonant contributions to $B^- \rightarrow \pi^+\pi^-\pi^-$ are summarized in Table III. The theoretical errors shown there are from the uncertainties in (i) the parameter $\alpha_{NR}$ [see Eq. (2.10)] which governs the momentum dependence of the nonresonant amplitude, (ii) the strange quark mass $m_{s}$ for decay modes involving kaon(s), the form factor $F_{0}^{B\pi}$ and the nonresonant parameter $\sigma_{NR}$ to be introduced below in Eq. (3.11), and (iii) the unitarity angle $\gamma$.

We see from Table III that the decay $B^- \rightarrow \pi^+\pi^-\pi^-$ is dominated by the $\rho^{0}$ pole and the nonresonant contribution. The calculated total branching fraction $(16.1^{+1.9}_{-2.3}) \times 10^{-6}$ agrees well with experiment.

**B. $\overline{B}^{0} \rightarrow \pi^{+}\pi^{-}\pi^{0}$ decay**

The factorizable amplitude of $\overline{B}^{0} \rightarrow \pi^{+}\pi^{-}\pi^{0}$ is given by

$$\langle \pi^{0}\pi^{+}\pi^{-}|T_{B}^{0}\overline{B}^{0}\rangle = \langle \pi^{+}\pi^{0}|(\overline{u}b)_{V-A}|\overline{B}^{0}\rangle\langle \pi^{-}|(\overline{d}u)_{V-A}|0\rangle \left[ a_{1}\delta_{p0} + a_{4}^{p} + a_{10}^{p} - \left( a_{6}^{p} + a_{8}^{p} \right) r_{\chi}^{p} \right]$$

$$+ \langle \pi^{+}\pi^{-}|(\overline{d}b)_{V-A}|\overline{B}^{0}\rangle\langle \pi^{0}|(\overline{u}u)_{V-A}|0\rangle \left[ a_{2}\delta_{p0} - a_{4}^{p} + \left( a_{6}^{p} - \frac{1}{2} a_{8}^{p} \right) r_{\chi}^{p} \right]$$

11
TABLE IV: Predicted branching fractions (in units of $10^{-6}$) of resonant and nonresonant (NR) contributions to $\overline{B}^0 \rightarrow \pi^+\pi^0$.

| Decay mode | Theory          | Decay mode | Theory          |
|------------|-----------------|------------|-----------------|
| $\rho^+\pi^-$ | $3.8^{+0.0+0.4+0.0}_{-0.0-0.3-0.0}$ | $\rho^0\pi^0$ | $1.0^{+0.2+0.0}_{-0.2-0.0}$ |
| $\rho^-\pi^+$ | $13.8^{+0.0+3.5+0.0}_{-0.0-3.1-0.1}$ | $f_0(980)\pi^0$ | $0.004^{+0.000+0.001+0.000}_{-0.000-0.001-0.000}$ |
| $\rho^\pm\pi^\mp$ | $17.8^{+0.0+3.6+0.0}_{-0.0-3.1-0.1}$ | NR | $1.6^{+0.5+0.0+0.0}_{-0.6-0.0-0.0}$ |
| Total      | $20.1^{+0.0+3.3+0.0}_{-0.3-3.3-0.1}$ |             |                 |

\[
\begin{align*}
&\frac{3}{2}(a_7 + a_9 + 12^2 a_{10}^R) + \langle \pi^+|\langle \overline{u}\overline{b} V_A|\overline{B}^0\rangle\langle \pi^-\pi^0|\langle \overline{d}\overline{u} V_A|0\rangle [a_1^R]\delta_{pa} + a_4^R + a_{10}^R] \\
&\langle \pi^0|\langle \overline{d}\overline{b} V_A|\overline{B}^0\rangle\langle \pi^+\pi^-|\langle \overline{u}\overline{u} V_A|0\rangle [a_2^R\delta_{pa} - a_4^R + \frac{3}{2}(a_7 + a_9) + \frac{1}{2} a_{10}^R] \\
&\langle \pi^0|\langle \overline{d}\overline{b} V_A|\overline{B}^0\rangle\langle \pi^+\pi^-|\overline{d}d|0\rangle(-2a_6^R + a_8^R). \\
\end{align*}
\]

It is obvious that while $B^- \rightarrow \pi^+\pi^-\pi^-$ is dominated by the $\rho^0$ resonance, the decay $\overline{B}^0 \rightarrow \pi^+\pi^-\pi^0$ receives intermediate $\rho^\pm$ and $\rho^0$ pole contributions. As a consequence, the $\pi^+\pi^-\pi^0$ mode has a rate larger than $\pi^+\pi^-\pi^-$ even though the former does not have two identical particles in the final state and moreover it involves a $\pi^0$ meson. Note that the calculated branching fractions of $\overline{B}^0 \rightarrow \rho^\pm\pi^\mp, \rho^0\pi^0$ shown in Table IV are consistent with the data (in units of $10^{-6}$), $23.0 \pm 2.3$ and $2.0 \pm 0.5$, respectively, measured from other processes. The nonresonant rate in $\overline{B}^0 \rightarrow \pi^+\pi^-\pi^0$ is fairly small because it is expected to be about four times smaller than that in $B^- \rightarrow \pi^+\pi^-\pi^-$. This is confirmed by a realistic calculation.

In Sec. V.C we shall explore the possibility if the large rate of $\overline{B}^0 \rightarrow K^+K^-\pi^0$ observed by Belle recently can arise from the decay $\overline{B}^0 \rightarrow \pi^+\pi^-\pi^0$ followed by final-state rescattering of $\pi^+\pi^- \rightarrow K^+K^-$.  

III. $B \rightarrow KKK$ DECAYS

A. $B^- \rightarrow K^+K^-K^-$ decay

The factorizable penguin-dominated $B^- \rightarrow K^+K^-K^-$ decay amplitude is given by

\[
\langle K^+K^-K^-|T_B^-|B^-\rangle = \langle K^+K^-|\langle \overline{u}\overline{b} V_A|\overline{B}^0\rangle\langle K^-|\langle \overline{s}\overline{u} V_A|0\rangle [a_1^R]\delta_{pa} + a_4^R + a_{10}^R - (a_6^R + a_8^R)r_X^K \\
+ \langle K^-|\langle \overline{u}\overline{b} V_A|\overline{B}^0\rangle\langle K^+K^-|\langle \overline{u}\overline{u} V_A|0\rangle [a_2^R\delta_{pa} + a_4^R + a_5 + a_7 + a_9] \\

\]

(3.1)
For the current-induced process with a kaon emission, the form factors $r$, $\omega_\perp$ and $h$ for the three-body matrix element $\langle K^+K^-|(\bar{u}b)_{V-A}|B^-\rangle$ [see Eq. (2.9)] evaluated in the framework of HMChPT are the same as that of Eq. (2.7) except that $B^*$ is replaced by $B^+_s$. As explained in the last section, the available phase space where chiral perturbation theory is applicable is only a small fraction of the whole Dalitz plot. Therefore, we have proposed to parameterize the $b \to u$ transition-induced nonresonant amplitude in an exponent form given in Eq. (2.9). The unknown parameter $\alpha_{NR}$ is determined from the data of the tree-dominated decay $B^- \to \pi^+\pi^-\pi^-$ and is given by Eq. (2.10).

In addition to the $b \to u$ tree transition, we need to consider the nonresonant contributions to the $b \to s$ penguin amplitude

$$A_1 = \langle K^-(p_1)|(\bar{s}b)_{V-A}|B^-\rangle\langle K^+(p_2)K^-(p_3)|(\bar{q}q)_{V-A}|0\rangle,$$

$$A_2 = \langle K^-(p_1)|\bar{s}b|B^-\rangle\langle K^+(p_2)K^-(p_3)|\bar{s}s|0\rangle. \quad (3.2)$$

The two-kaon creation matrix element can be expressed in terms of time-like kaon current form factors as

$$\langle K^+(p_{K^+})K^-(p_{K^-})|\bar{q}\gamma\mu q|0\rangle = (p_{K^+} - p_{K^-})_\mu F^+_q K^+, \quad \langle K^0(p_{K^0})\overline{K}^0(p_{\overline{K}^0})|\bar{q}\gamma\mu q|0\rangle = (p_{K^0} - p_{\overline{K}^0})_\mu F^0_q K^0. \quad (3.3)$$

The weak vector form factors $F^{K^+K^-}$ and $F^{K^0\overline{K}^0}$ can be related to the kaon electromagnetic (e.m.) form factors $F^{em}_{K^+K^-}$ and $F^{em}_{K^0\overline{K}^0}$ for the charged and neutral kaons, respectively. Phenomenologically, the e.m. form factors receive resonant and nonresonant contributions and can be expressed by

$$F^{em}_{K^+K^-} = F^\rho_{K^+} F^\omega_{K^-} + F^\phi_{K^+} F^{K^+K^-}_{NR}, \quad F^{em}_{K^0\overline{K}^0} = -F^\rho_{K^0} + F^\omega_{K^0} F^{K^0\overline{K}^0}_{NR} + F^\phi_{K^0}. \quad (3.4)$$

It follows from Eqs. (3.3) and (3.4) that

$$F^u_{K^+K^-} = F^d_{K^0\overline{K}^0} = F^\rho_{K^+} + 3 F^\omega_{K^-} + \frac{1}{3} (3 F^{s}_{NR} - F^{s}_{NR}),$$

$$F^d_{K^+K^-} = F^u_{K^0\overline{K}^0} = -F^\rho_{K^+} + 3 F^\omega_{K^-},$$

$$F^s_{K^+K^-} = F^s_{K^0\overline{K}^0} = -3 F^\phi_{K^-} - \frac{1}{3} (3 F^{s}_{NR} + 2 F^{s}_{NR}). \quad (3.5)$$

where use of isospin symmetry has been made.

The resonant and nonresonant terms in Eq. (3.4) can be parameterized as

$$F_h(s) = \frac{c_h}{m_h^2 - s - i m_h \Gamma_h}, \quad F^{(t)}_{NR}(s) = \left(\frac{x_1(t)}{s} + \frac{x_2(t)}{s^2}\right) \left[\ln\left(\frac{s^2_3}{\Lambda^2}\right)\right]^{-1}, \quad (3.6)$$

with $\Lambda \approx 0.3 \text{ GeV}$. The expression for the nonresonant form factor is motivated by the asymptotic constraint from pQCD, namely, $F(t) \to (1/t)\ln(t/\Lambda^2)^{-1}$ in the large $t$ limit [46]. The unknown parameters $c_h$, $x_1$, and $x'_2$ are fitted from the kaon e.m. data, giving the best fit values (in units of $\text{GeV}^2$ for $c_h$) [47]:

$$c_\rho = 3 c_\omega = c_\phi = 0.363, \quad c_\rho(1450) = 7.98 \times 10^{-3}, \quad c_\rho(1700) = 1.71 \times 10^{-3},$$

$$c_\omega(1420) = -7.64 \times 10^{-2}, \quad c_\omega(1650) = -0.116, \quad c_\phi(1680) = -2.0 \times 10^{-2}, \quad (3.7)$$

13
and
\[ x_1 = -3.26 \text{ GeV}^2, \quad x_2 = 5.02 \text{ GeV}^2, \quad x'_1 = 0.47 \text{ GeV}^2, \quad x'_2 = 0. \tag{3.8} \]

Note that the form factors \( F_{\rho,\omega,\phi} \) in Eqs. (3.4) and (3.5) include the contributions from the vector mesons \( \rho(770) \), \( \rho(1450) \), \( \rho(1700) \), \( \omega(782) \), \( \omega(1420) \), \( \omega(1650) \), \( \phi(1020) \) and \( \phi(1680) \). As a cross check, following the derivation of the resonant component of \( \langle \pi^+\pi^-|\bar{u}\gamma_\mu u|0\rangle \) in Eq. (2.17) we obtain the resonant contributions to the \( K^+K^- \) transition form factors
\[
F_{u,R}^{K^+K^-}(s) = -\frac{1}{\sqrt{2}} \left( \sum_i m_{\rho_i} f_{\rho_i} g_{\rho_i \rightarrow K^+K^-} \left( s - m_{\rho_i}^2 + i m_{\rho_i} \Gamma_{\rho_i} \right) + \sum_i m_{\omega_i} f_{\omega_i} g_{\omega_i \rightarrow K^+K^-} \left( s - m_{\omega_i}^2 + i m_{\omega_i} \Gamma_{\omega_i} \right) \right),
\]
\[
F_{d,R}^{K^+K^-}(s) = \frac{1}{\sqrt{2}} \left( \sum_i m_{\rho_i} f_{\rho_i} g_{\rho_i \rightarrow K^+K^-} \left( s - m_{\rho_i}^2 + i m_{\rho_i} \Gamma_{\rho_i} \right) - \sum_i m_{\omega_i} f_{\omega_i} g_{\omega_i \rightarrow K^+K^-} \left( s - m_{\omega_i}^2 + i m_{\omega_i} \Gamma_{\omega_i} \right) \right),
\]
\[
F_{s,R}^{K^+K^-}(s) = -\sum_i \frac{m_{\phi_i} f_{\phi_i} g_{\phi_i \rightarrow K^+K^-}}{s - m_{\phi_i}^2 + i m_{\phi_i} \Gamma_{\phi_i}}. \tag{3.9} \]

Using the quark model result \( g^{\rho\rightarrow K^+K^-} : g^{\omega\rightarrow K^+K^-} : g^{\phi\rightarrow K^+K^-} = 1 : 1 : -1/\sqrt{2} \) to fix the relative sign of strong couplings and noting that \( g^{\phi\rightarrow K^+K^-} = -4.54 \) determined from the measured \( \phi \rightarrow K^+K^- \) rate, we find \( c_\phi = -\frac{1}{3} m_{\phi} f_{\phi} g^{\phi\rightarrow K^+K^-} = 0.340 \) in agreement with \( c_\phi = 0.363 \) obtained from a fit to the kaon e.m. data.

The use of the equation of motion thus leads to
\[
A_1 = (s_{12} - s_{13}) F_1^{BK}(s_{23}) F_d^{K^+K^-}(s_{23}),
\]
\[
A_2 = \frac{m_B^2 - m_K^2}{m_b - m_s} F_0^{BK}(s_{23}) F_s^{K^+K^-}(s_{23}), \tag{3.10} \]
where the matrix element \( f_s^{K^+K^-} \) receives both resonant and non-resonant contributions:
\[
\langle K^+(p_2)K^-(p_3)|\bar{s}s|0\rangle \equiv f_s^{K^+K^-}(s_{23}) = \sum_i \frac{m_{f_{0_i}} f_{f_{0_i}} g_{f_{0_i} \rightarrow K^+K^-}}{m_{f_{0_i}}^2 - s_{23} - i m_{f_{0_i}} \Gamma_{f_{0_i}}} + f_s^{NR},
\]
\[
f_s^{NR} = \frac{v}{3} (3 F_{NR} + 2 F'_{NR}) + \sigma_{NR} e^{-\alpha s_{23}}. \tag{3.11} \]
with
\[
v = \frac{m_{K^+}^2}{m_u + m_s} = \frac{m_{K^-}^2}{m_d + m_s}, \tag{3.12} \]
characterizing the quark-order parameter \( \langle \bar{q}q \rangle \) which spontaneously breaks the chiral symmetry. The nonresonant \( \sigma_{NR} \) term is introduced for the following reason. Although the nonresonant contributions to \( f_s^{KK} \) and \( F_s^{KK} \) are related through the equation of motion, the resonant ones are different and not related \textit{a priori}. As stressed in [48], to apply the equation of motion, the form factors should be away from the resonant region. In the presence of resonances, we thus need to introduce a nonresonant \( \sigma_{NR} \) term which can be constrained by the measured \( \overline{B}^0 \rightarrow K_S K_S K_S \) rate and the \( K^+K^- \) mass spectrum measured in \( \overline{B}^0 \rightarrow K^+K^- K_S \) [31]. The parameter \( \alpha \) appearing in the same equation should be close to the value of \( \alpha_{NR} \) given in Eq. (2.10). We will use the experimental measurement \( \alpha \approx 0.14 \pm 0.02 \text{ GeV}^{-2} \) [49].
It is known that in the narrow width approximation, the three-body decay rate obeys the factorization relation
\[ \Gamma(B \rightarrow RP \rightarrow P_1 P_2 P) = \Gamma(B \rightarrow RP) B(R \rightarrow P_1 P_2), \tag{3.13} \]
with \( R \) being a resonance. This means that the amplitudes \( A(B \rightarrow RP \rightarrow P_1 P_2 P) \) and \( A(B \rightarrow RP) \) should have the same expressions apart from some factors. Hence, using the known results for contribution to \( B \) and \( s \) purely an factorization relation
Comparing this equation with Eq. (A6) of \([50]\), we see that the expression inside \( a \) and \( B \) to that of \( R \) of the light scalar mesons below or near 1 GeV has been quite controversial. In this work we shall digress for a moment to discuss the wave function of the \( f_0(980) \). What is the quark structure of the light scalar mesons below or near 1 GeV has been quite controversial. In this work we shall consider the conventional \( q\bar{q} \) assignment for the \( f_0(980) \). In the naive quark model, the flavor wave functions of the \( f_0(980) \) and \( f_0(500) \) (or \( \sigma \) meson) read
\[ f_0(500) = \frac{1}{\sqrt{2}} (u\bar{u} + d\bar{d}), \quad f_0(980) = s\bar{s}, \tag{3.15} \]
where ideal mixing for \( f_0(980) \) and \( f_0(500) \) has been assumed. In this picture, \( f_0(980) \) is purely an \( s\bar{s} \) state. However, there also exist some experimental evidences indicating that \( f_0(980) \) is not purely an \( s\bar{s} \) state. First, the observation of \( \Gamma(J/\psi \rightarrow f_0 \omega) \approx \frac{1}{4} \Gamma(J/\psi \rightarrow f_0 \phi) \) clearly indicates the existence of the non-strange and strange quark content in \( f_0(980) \). Second, the fact that \( f_0(980) \) and \( a_0(980) \) have similar widths and that the \( f_0(980) \) width is dominated by \( \pi\pi \) also suggests the composition of \( u\bar{u} \) and \( d\bar{d} \) pairs in \( f_0(980) \); that is, \( f_0(980) \rightarrow \pi\pi \) should not be OZI suppressed relative to \( a_0(980) \rightarrow \pi\eta \). Therefore, isoscalars \( f_0(500) \) and \( f_0(980) \) must have a mixing
\[ |f_0(500)\rangle = -|s\bar{s}\rangle \sin \theta + |n\bar{n}\rangle \cos \theta, \quad |f_0(980)\rangle = |s\bar{s}\rangle \cos \theta + |n\bar{n}\rangle \sin \theta, \tag{3.16} \]
with \( n\bar{n} = (u\bar{u}+d\bar{d})/\sqrt{2} \). Experimental implications for the \( f_0(980) \)–\( f_0(500) \) mixing angle have been discussed in detail in \([52]\). Assuming 2-quark bound states for \( f_0(980) \) and \( f_0(500) \), the observed

\[ 4 \text{ There are some sign typos in Eq. (A6) of \([40]\) including the one in the amplitude of } B^- \rightarrow f_0 K^- \text{. When comparing Eq. (3.14) with Eq. (A1) of \([51]\) \text{, we see that some terms are missing in Eq. (3.14). This is because one has to consider the convolution with the light-cone distribution amplitude of the } f_0(980) \text{ in the approach of QCDF. As a consequence, the amplitude for } f_0 \text{ emission does not vanish in QCDF. We will not consider those subtitles in the simple factorization approach adapted here.} \]
TABLE V: Branching fractions (in units of $10^{-6}$) of resonant and nonresonant (NR) contributions to $B^- \to K^+ K^- K^-$, $B^0 \to K^+ K^- K^0$, $B^- \to K^- K_S K_S$ and $\bar{B}^0 \to K_S K_S K_S$.

$^a$The LHCb measurement is $B(B^0 \to K^+ K^- K^0) = (19.1 \pm 1.5 \pm 1.1 \pm 0.8) \times 10^{-6}$ [19].
large rates of $B^{-} \to f_{0}(980) K$ and $f_{0}(980)K^{*}$ modes can be explained in QCDF with the mixing angle $\theta$ in the vicinity of $20^\circ$ [51]. In this work, we shall use $\theta = 20^\circ$.

Finally, the matrix elements involving three-kaon creation are given by

$$
\langle K^0(p_1)K^+(p_2)K^-((s d)_{V-A}[0]\langle 0|(|dB|_{V-A}|\overline{B}^3) \approx 0, \\
\langle K^0(p_1)K^+(p_2)K^-((s d)_{V-A}|0\rangle d_5 (db)_{V-A}|\overline{B}^3) = e f_B m_B^2 (1 - \frac{s_{13} - m_d^2 - m_{B}^2}{m_B^2 - m_K^2}) F_{KKK}(m_B^2).
$$

Both relations in Eq. (3.17) are originally derived in the chiral limit [41] and hence the quark masses appearing in Eq. (3.12) are referred to the scale $\sim 1$ GeV. The first relation reflects helicity suppression which is expected to be even more effective for energetic kaons. For the second relation, we introduce the form factor $F_{KKK}$ to extrapolate the chiral result to the physical region. Following [41], we shall take $F_{KKK}(q^2) = 1/[1 - (q^2/\Lambda_{\chi}^2)]$ with $\Lambda_{\chi} = 0.83$ GeV being a chiral symmetry breaking scale.

To proceed with the numerical calculations, we shall assume that the main scalar meson contributions are those that have dominant $s\bar{s}$ content and large coupling to $K\overline{K}$. We consider the scalar mesons $f_{0}(980)$, $f_{0}(1500)$ and $f_{0}(1710)$ which are supposed to have the largest couplings with the $K\overline{K}$ pair. More specifically, we shall use $g_{0}^{f_{0}(980)\to K^{+}K^{-}} = 3.7$ GeV, $g_{0}^{f_{0}(1500)\to K^{+}K^{-}} = 0.69$ GeV, $g_{0}^{f_{0}(1710)\to K^{+}K^{-}} = 1.6$ GeV, $\Gamma_{f_{0}(980)} = 80$ MeV, $\Gamma_{f_{0}(1500)} = 0.109$ GeV, $\Gamma_{f_{0}(1710)} = 0.135$ GeV, $f_{0}^{f_{0}(980)}(m_{b}/2) \simeq 0.46$ GeV [53], $f_{0}^{f_{0}(1500)} \simeq 0.30$ GeV and $f_{0}^{f_{0}(1710)} \simeq 0.17$ GeV. As for the parameter $\sigma_{NR}$ in Eq. (3.11), its magnitude can be determined from the measured $K_{S}K_{S}K_{S}$ rate, namely, $B(B^{0} \to K_{S}K_{S}K_{S}) = (6.1 \pm 0.5) \times 10^{-6}$ [5]. As to the strong phase $\phi_{s}$, we follow [31] to take $\phi_{s} \approx \pi/4$ which yields $K^{+}K^{-}$ mass spectrum in $\overline{B}^0 \to K^{+}K^{-}K_{S}$ consistent with the data

$$
\sigma_{NR} = e^{i\pi/4}(3.39_{-0.21}^{+0.18}) \text{ GeV}. \quad (3.18)
$$

The calculated branching fractions of resonant and nonresonant contributions to $B^{-} \to K^{+}K^{-}K^{-}$, $\overline{B}^0 \to K^{+}K^{-}K^{0}$, $B^{-} \to K^{-}K_{S}K_{S}$ and $\overline{B}^0 \to K_{S}K_{S}K_{S}$ are depicted in Table V. The factorizable amplitudes of the last three modes can be found in Appendix A of [31]. Note that both BaBar and Belle used to see a broad scalar resonance $f_{X}(1500)$ in $B \to K^{+}K^{+}K^{-}$, $K^{+}K^{-}K_{S}$ and $K^{+}K^{-}\pi^{+}$ decays at energies around 1.5 GeV. However, the nature of $f_{X}(1500)$ is not clear as it cannot be identified with the well known scalar meson $f_{0}(1500)$. Nevertheless, the recent angular-momentum analysis of the above-mentioned three channels by BaBar [12] shows that the $f_{X}(1500)$ state is not a single scalar resonance, but instead can be described by the sum of the well-established resonances $f_{0}(1500)$, $f_{0}(1710)$ and $f_{2}^{'}(1525)$.

From Table V it is obvious that the predicted rates for resonant and nonresonant components are consistent with experiment within errors. It is known that the calculated $B(\overline{B} \to \phi K)$ is smaller than experiment and this rate deficit problem calls for the $1/m_{b}$ power corrections from penguin annihilation. A unique feature of hadronic $B \to KKK$ decays is that they are predominated by the nonresonant contributions with nonresonant fraction of order 80%. The nonresonant background due to the current-induced process through $B \to KK$ transition accounts only 5% of the observed nonresonant contributions as it is suppressed by the parameter $\alpha_{NR}$. This implies that the two-body matrix element of scalar densities e.g. $\langle K\overline{K} s\bar{s}|0\rangle$ induced from the penguin diagram should have a large nonresonant component. This is plausible because the decay $B \to KKK$ is dominated by the
\( b \to s \) penguin transition. Consequently, it is natural to expect that the nonresonant contribution to this decay is also penguin-dominated.

IV. \( B \to K\pi\pi \) DECAYS

The factorizable penguin-dominated \( B^- \to K^-\pi^+\pi^- \) decay amplitude has the expression

\[
\langle K^-\pi^+\pi^-|T_p|B^- \rangle = \langle \pi^+\pi^-|(\bar{u}b)_{V-A}|B^- \rangle\langle K^-|(\bar{s}u)_{V-A}|0 \rangle \left[ a_1 \delta_{pu} + a_2^p + a_4^p + a_1^T 0 - (a_6^p + a_9^p) \chi \right] \\
+ \langle (\bar{s}b)_{V-A}|B^- \rangle\langle \pi^+\pi^-|(\bar{u}u)_{V-A}|0 \rangle \left[ a_2 \delta_{pu} + a_3 + a_5 + a_7 + a_9 \right] \\
+ \langle (\bar{s}b)_{V-A}|B^- \rangle\langle \pi^+\pi^-|(\bar{d}d)_{V-A}|0 \rangle \left[ a_3 + a_5 - \frac{1}{2} (a_7 + a_9) \right] \\
+ \langle (\bar{s}b)_{V-A}|B^- \rangle\langle \pi^+\pi^-|(\bar{s}s)_{V-A}|0 \rangle \left[ a_3 + a_5 + a_5 + \frac{1}{2} (a_7 + a_9 + a_{10}^p) \right] \\
+ \langle (\bar{s}b)_{B^-}\rangle\langle \pi^+\pi^-|s\bar{s}|0 \rangle \left( -2a_6^p + a_8^p \right) \\
+ \langle \pi^-|(db)_{V-A}|B^- \rangle\langle K^-\pi^+|(\bar{s}d)_{V-A}|0 \rangle \left( a_4^p - \frac{1}{2} a_{10}^p \right) \\
+ \langle \pi^-|(db)_{B^-}\rangle\langle K^-\pi^+|\bar{s}d|0 \rangle \left( -2a_6^p + a_8^p \right) \\
+ \langle (\bar{s}u)_{V-A}|0 \rangle\langle p|0 \rangle\langle \bar{u}b\rangle_{V-A}|B^- \rangle\langle a_1 \delta_{pu} + a_2^p + a_4^p \rangle \\
+ \langle (\bar{s}u)_{V-A}|0 \rangle\langle p|0 \rangle\langle \bar{u}b\rangle_{V-A}|B^- \rangle\langle a_1 \delta_{pu} + a_2^p + a_4^p \rangle.
\]

The factorizable amplitudes for other \( \bar{B} \to K\pi\pi \) modes such as \( B^- \to \bar{K}^0\pi^+\pi^- \), \( \bar{B}^0 \to K^-\pi^+\pi^- \), \( \bar{K}^0\pi^+\pi^- \) and \( K^0\pi^+\pi^- \) can be found in Appendix A of \[31\]. The expression of \( A(B^- \to K^-\pi^0\pi^0) \) is given in Eq. [31]. All six channels have the three-body matrix element \( \langle \pi\pi|(\bar{q}b)_{V-A}|B \rangle \) which has the similar expression as Eqs. [2.7] and [2.8]. The three-body matrix elements also receive resonant contributions, for example,

\[
\langle K^- (p_1)\pi^+(p_2)|\langle \bar{s}b\rangle_{V-A}|B^0 \rangle^R = \sum_s \frac{g_{K_s^-\to K^-\pi^+}}{s_{12} - m_{K_s^-}^2 + im_{K_s^-} \Gamma_{K_s^-}} \sum_{pol} \epsilon^* \cdot (p_1 - p_2) \langle \bar{K}_s^0 |\langle \bar{s}b\rangle_{V-A}|B^0 \rangle,
\]

\[
- \sum_s \frac{g_{K_s^0\to K^-\pi^+}}{s_{12} - m_{K_s^0}^2 + im_{K_s^0} \Gamma_{K_s^0}} \langle \bar{K}_s^0 |\langle \bar{s}b\rangle_{V-A}|B^0 \rangle,
\]

with \( K_7^* = K^*(892), K^*(1410), K^*(1680), \cdots, \) and \( K_6^0 = K_7^0(1430) \).

For the two-body matrix elements \( \langle \pi^+K^-|\langle \bar{s}d\rangle_{V-A}|0 \rangle, \langle \pi^+\pi^-|\langle \bar{u}u\rangle_{V-A}|0 \rangle \) and \( \langle \pi^+\pi^-|\bar{s}\bar{s}|0 \rangle \), we note that

\[
\langle K^- (p_1)\pi^+(p_2)|\langle \bar{s}d \rangle_{V-A}|0 \rangle = \langle \pi^+(p_2)|\langle \bar{s}d \rangle_{V-A}|K^+(-p_1) \rangle = (p_1 - p_2)_\mu F_1^{K\pi}(s_{12}) \\
+ \frac{m_K^2 - m_{\pi}^2}{s_{12}} (p_1 + p_2)_\mu \left[ - F_1^{K\pi}(s_{12}) + F_0^{K\pi}(s_{12}) \right],
\]

where we have taken into account the sign flip arising from interchanging the operators \( s \leftrightarrow d \). The resonant contributions are

\[
\langle K^- (p_1)\pi^+(p_2)|\langle \bar{s}d \rangle_{V-A}|0 \rangle^R = \sum_s \frac{g_{K_s^*\to K^-\pi^+}}{s_{12} - m_{K_s^*}^2 + im_{K_s^*} \Gamma_{K_s^*}} \sum_{pol} \epsilon^* \cdot (p_1 - p_2) \langle K_s^* |\langle \bar{s}d \rangle_{V-A}|0 \rangle \\
- \sum_s \frac{g_{K_s^{0*}\to K^-\pi^+}}{s_{12} - m_{K_s^{0*}}^2 + im_{K_s^{0*}} \Gamma_{K_s^{0*}}} \langle K_s^{0*} |\langle \bar{s}d \rangle_{V-A}|0 \rangle,
\]

18
Hence, form factors $F_1^{K\pi}$ and $(-F_1^{K\pi} + F_0^{K\pi})$ receive the following resonant contributions

$$
(F_1^{K\pi}(s))^R = \sum \frac{m_{K_i} f_{K_i} g_{K_i}^{K\pi}}{m_{K_i}^2 - s - i m_{K_i} \Gamma_{K_i}},
$$

$$
(-F_1^{K\pi}(s) + F_0^{K\pi}(s))^R = \sum \frac{m_{K_0}^2 f_{K_0}^* g_{K_0}^{K\pi}}{m_{K_0}^2 - s - i m_{K_0} \Gamma_{K_0}} \frac{s_{12}}{s_1^2}
- \sum \frac{m_{K_i}^2 f_{K_i} g_{K_i}^{K\pi}}{m_{K_i}^2 - s - i m_{K_i} \Gamma_{K_i} m_{K_i}^2} \frac{s_{12}}{s_1^2}.
$$

Note that for the scalar meson, the decay constant $f_S$ is defined in Eq. (2.13), while $f_S$ is defined by $\langle S(p) | \bar{q} \gamma_{\mu} q | 0 \rangle = f_{S\mu}$. The two decay constants are related by equations of motion 50

$$
\mu_S f_S = \bar{f}_S, \quad \text{with} \quad \mu_S = \frac{m_S}{m_2(\mu) - m_1(\mu)},
$$

where $m_2$ and $m_1$ are the running current quark masses. The nonresonant contribution $\langle \pi^+(p_2)\pi^-(p_3) | \bar{s}s | 0 \rangle$ vanishes under the OZI rule.

Now, the amplitude $\langle K^- \pi^+ | (\bar{s}d)_{V-A} | 0 \rangle \langle \pi^- | (\bar{d}b)_{V-A} | B^- \rangle$ in Eq. (4.1) has the expression

$$
\langle K^- (p_1)\pi^+(p_2) | (\bar{s}d)_{V-A} | 0 \rangle \langle \pi^- (p_3) | (\bar{d}b)_{V-A} | B^- \rangle = F_1^{B\pi}(s_{12}) F_1^{K\pi}(s_{12}) \left[ s_{23} - s_{13} - \frac{(m_2^2 - m_1^2)(m_2^0 - m_1^0)}{s_{12}} \right]
+ F_0^{B\pi}(s_{12}) F_0^{K\pi}(s_{12}) \frac{(m_2^2 - m_1^2)(m_2^0 - m_1^0)}{s_{12}}.
$$

with

$$
\langle K^- (p_1)\pi^+(p_2) | (\bar{s}d) | 0 \rangle = \sum \frac{m_{K_0}^2 \bar{f}_{K_0}^* g_{K_0}^{K\pi} \longrightarrow K^- \pi^+}{m_{K_0}^2 - s_{12} - i m_{K_0} \Gamma_{K_0}} + \langle K^- (p_1)\pi^+(p_2) | (\bar{s}d) | 0 \rangle NR.
$$

We consider the factorizable amplitude of the weak decay $B^- \rightarrow K_0^{*0}(1430)\pi^-$ followed by the strong decay $K_0^{*0}(1430) \rightarrow K^- \pi^+$ as a cross check on the three-body decay amplitude of $B \rightarrow RP \rightarrow P_1 P_2 P$. From Eq. (4.11) we obtain

$$
\langle K^- (p_1)\pi^+(p_2)\pi^-(p_3) | T_B | B^- \rangle_{K_0^{*0}(1430)} = \frac{g_{K_0^{*0}(1430) \rightarrow K^- \pi^+}}{m_{K_0^{*0}(1430)}^2 - s_{12} - i m_{K_0^{*0}} \Gamma_{K_0^{*0}}} \left\{ \left( a_4 - r_{\chi K_0^{*0}} a_6 - \frac{1}{2} (a_{10} - r_{\chi K_0^{*0}} a_8) \right) f_{K_0^{*0}} F_0^{B\pi}(m_{K_0^{*0}}^2)(m_2^2 - m_1^2) \right\},
$$

where

$$
r_{\chi K_0}(\mu) = \frac{2 m_{K_0}^2}{m_b(\mu)(m_6(\mu) - m_q(\mu))}.
$$

The expression inside $\{ \cdots \}$ agrees with the amplitude of $B^0 \rightarrow K_0^{*0}(1430)\pi^0$ given in Eq. (A6) of 50.

The momentum dependence of the weak form factor $F^{K\pi}(q^2)$ is parameterized as

$$
F^{K\pi}(q^2) = \frac{F^{K\pi}(0)}{1 - q^2/\Lambda_{\chi}^2 + i \Gamma_R/\Lambda_{\chi}},
$$

(4.11)
TABLE VI: Branching fractions (in units of $10^{-6}$) of resonant and nonresonant (NR) contributions to $B^- \to K^-\pi^+\pi^-$, $B^- \to K^-\pi^0\pi^0$, $\overline{B}^0 \to \overline{K}^0\pi^+\pi^-$ and $\overline{B}^0 \to K^-\pi^+\pi^0$. Note that the BaBar result for $K^0_0(1430)\pi^-$ in \cite{4}, $K^0_0^- (1430)\pi^+$ in \cite{4}, all the BaBar results in \cite{17} and Belle results in \cite{16} are their absolute ones. We have converted them into the product branching fractions, namely, $B(B \to Rh) \times B(R \to hh)$.

with $\Gamma_R$ being the width of the relevant resonance, which is taken to be 200 MeV [41].

It should be stressed that the nonresonant branching fraction $(2.4 \pm 0.5^{+1.0}_{-1.3}) \times 10^{-6}$ in $B^- \rightarrow K^- \pi^+ \pi^-$ reported by BaBar [4] is much smaller than the one $(16.9 \pm 1.3^{+1.7}_{-1.6}) \times 10^{-6}$ measured by Belle (see Table VII). Since the BaBar and Belle definitions of the $K^*_0(1430)$ and nonresonant contribution differ, it does not make sense to compare the branching fractions and phases directly. While Belle (see e.g. [5]) employed an exponential parametrization to describe the nonresonant contribution, BaBar [4] used the LASS parametrization to describe the $K \pi$ S-wave and the nonresonant component by a single amplitude suggested by the LASS collaboration. While this approach is experimentally motivated, the use of the LASS parametrization is limited to the elastic region of $M(K \pi) \lesssim 2.0$ GeV, and an additional amplitude is still required for a satisfactory description of the data. In short, the BaBar definition for the $K^*_0(1430)$ includes an effective range term to account for the low-energy $K \pi$ S-wave, while for the Belle parameterization, this component is absorbed into the nonresonant piece. For the example at hand, the aforementioned BaBar result $B(B^- \rightarrow K^- \pi^+ \pi^-)_{NR}$ is solely due to the phase-space nonresonant piece. It is clear that part of the LASS shape is really nonresonant which has a substantial mixing with $K^*_0(1430)$. In principle, this should be added to the phase-space nonresonant piece to get the total nonresonant contribution. Indeed, by combining coherently the nonresonant part of the LASS parametrization and the phase-space nonresonant, BaBar found the total nonresonant branching fraction to be $(9.3 \pm 1.0 \pm 1.2^{+6.8}_{-1.3}) \times 10^{-6}$. We see from Table VII that the BaBar result is now consistent with Belle within errors, though the agreement is not perfect. Likewise, the branching fraction $(2.8 \pm 0.5 \pm 0.4) \times 10^{-6}$ of phase-space nonresonant contribution to $B^0 \rightarrow K^- \pi^+ \pi^0$ measured by BaBar [16] is now modified to $(7.6 \pm 0.5 \pm 1.0) \times 10^{-6}$ when the nonresonant part of the LASS parametrization is added coherently to the phase-space nonresonant piece (see Table VII).

For the resonant contributions from $K^*_0(1430)$, the branching fractions of the quasi-two-body decays $B \rightarrow K^*_0(1430) \pi$ can be inferred from Table VII and the results are shown in Table IX below. From the table we see that the measured branching fractions of $K^*_0(1430) \pi^+$ and $K^*_0(1430) \pi^-$
channels are of order $30 \times 10^{-6}$ by BaBar and $50 \times 10^{-6}$ by Belle. Note that the BaBar results are obtained from $(K\pi)_0^0\pi^-$ and $(K\pi)_0^+\pi^+$ by subtracting the elastic range term from the $K\pi$ S-wave [4, 14]. For example, the BaBar result shown in Table VII for the branching fraction of $K^0(1430)\pi^-$ comes only from the Breit-Wigner component of the LASS parametrization, while the nonresonant contribution includes both the nonresonant part of the LASS shape and the phase-space nonresonant piece. Nevertheless, the discrepancy between BaBar and Belle for the $K^*_0\pi$ modes still remains and it is crucial to resolve this important issue.

Experimentally, the nonresonant rates in $B^- \rightarrow K^-\pi^+\pi^-$ and $B^0 \rightarrow K^0\pi^+\pi^-$ are of the same order of magnitude as that in $B \rightarrow KKK$ decays (see Tables V and VI). Indeed, this is what we will expect. The nonresonant components of $B \rightarrow KKK$ are governed by the $KK\pi$ matrix element $\langle K\pi|\bar{s}s|0\rangle$. By the same token, the nonresonant contribution to the penguin-dominated $B \rightarrow K\pi\pi$ decays should be also dominated by the $K\pi$ matrix element, namely, $\langle K\pi|\bar{s}q|0\rangle$. Its precise expression will be given in Eq. (7.11) below. The reason why the nonresonant fraction is as large as 90% in $KKK$ decays, but becomes only $(17 \sim 40)\%$ in $K\pi\pi$ channels (see Table II) can be explained as follows. The nonresonant rates in the $K^-\pi^+\pi^-$ and $K^0\pi^+\pi^-$ modes should be similar to that in $K^+K^-\overline{K}^0$ or $K^+K^-K^-$. Since the $KKK$ channel receives resonant contributions only from $\phi$ and $f_0$ mesons, while $K^*, K^*_0, \rho, f_0$ resonances contribute to $K\pi\pi$ modes, this explains why the nonresonant fraction is of order 90% in the former and becomes of order 40% or smaller in the latter.

The results of our calculation are shown in Tables VI and VII. It is obvious that except for $f_0(980)K$, the predicted rates for $K^*\pi$, $K^*_0(1430)\pi$ and $\rho K$ are smaller than the data. Indeed, the predictions based on QCD factorization for these decays are also generally smaller than experiment by a factor of 2~5. This will be discussed in more details in Sec. VI. As a result, this also explain why our predictions of the total branching fractions of $B \rightarrow K\pi\pi$ are smaller than experiment.

V. $B \rightarrow KKK\pi$ DECAYS

In this section we turn to the three-body decay modes $KK\pi$ dominated by $b \rightarrow u$ tree and $b \rightarrow d$ penguin transitions.

A. $B^- \rightarrow K^+K^-\pi^-$ decay

The factorizable tree-dominated $B^- \rightarrow K^+K^-\pi^-$ decay amplitude reads

$$
\langle \pi^- K^+ K^- | T_p | B^- \rangle = \langle K^+ K^- | (\bar{u}b)_{V-A} | B^- \rangle \langle \pi^- | (d\bar{u})_{V-A} | 0 \rangle \left[ a_1 \delta_{pu} + a_4^p + a_{10}^p - (a_6^p + a_8^p) r_X^\pi \right] \\
+ \langle \pi^- | (\bar{b}d)_{V-A} | B^- \rangle \langle K^+ K^- | (\bar{u}u)_{V-A} | 0 \rangle (a_2 \delta_{pu} + a_3 + a_5 + a_7 + a_9) \\
+ \langle \pi^- | (\bar{b}d)_{V-A} | B^- \rangle \langle K^+ K^- | (\bar{d}d)_{V-A} | 0 \rangle \left[ a_3 + a_4^p + a_5 - \frac{1}{2} (a_7 + a_9 + a_{10}^p) \right] \\
+ \langle \pi^- | (\bar{b}d)_{V-A} | B^- \rangle \langle K^+ K^- | (\bar{s}s)_{V-A} | 0 \rangle \left[ a_3 + a_5 - \frac{1}{2} (a_7 + a_9) \right] \\
+ \langle \pi^- | (\bar{d}b)_{V-A} | B^- \rangle \langle K^+ K^- | (\bar{d}d)_{V-A} | 0 \rangle (-2a_6^p + a_8^p)
$$
\begin{eqnarray}
+ & & \langle K^- | (\bar{s}b)_V - A | B^- \rangle \langle K^+ | \pi^- | (\bar{d}s)_V - A | 0 \rangle (a^p_4 - \frac{1}{2} a^p_{10}) \\
+ & & \langle K^- | (\bar{s}b) | B^- \rangle \langle K^+ | \pi^- | d | 0 \rangle (-2 a^p_6 + a^p_8) \\
+ & & \langle K^+ | K^- | (\bar{d}u)_V - A | 0 \rangle \langle (\bar{u}b)_V - A | B^- \rangle \left( a_1 \delta_{pu} + a^p_4 + a^p_{10} \right) \\
+ & & \langle K^+ | K^- | \bar{d}(1 + \gamma_5) u | 0 \rangle \langle (\bar{u} \gamma_5 b) | B^- \rangle (2 a^p_6 + 2 a^p_8). \\
\end{eqnarray}

Just as the $B^- \rightarrow \pi^- \pi^- \pi^-$ decay, the branching fraction of the nonresonant contribution due to the $b \rightarrow u$ tree transition will be too large, of order $42 \times 10^{-6}$, if it is evaluated solely based on HMChPT. Hence, the momentum dependence of nonresonant amplitudes in an exponential form given by Eq. (2.9) has to be introduced.

Note that we have included the matrix element $\langle K^+ | K^- | \bar{d}d | 0 \rangle$. Although its nonresonant contribution vanishes as $K^+$ and $K^-$ do not contain the valence $d$ or $\bar{d}$ quark, this matrix element does receive a nonresonant contribution from the scalar $f_0$ pole

$$\langle K^+ | p_2 \rangle K^- | p_3 \rangle | \bar{d}d | 0 \rangle_R = \sum_i \frac{m_f f_i}{m^2_{f_0} - s_{23} - i m_{f_0} \Gamma_{f_0}},$$

where $\langle f_0 | \bar{d}d | 0 \rangle = m_{f_0} f_{f_0}$. In the 2-quark model for $f_0(980)$, $f_{f_0} f_{f_0}(980) = f_{f_0}(980) \sin \theta / \sqrt{2}$. Also note that the matrix element $\langle K^- | p_3 \rangle | (\bar{s}b)_V - A | B^- \rangle \langle \pi^- | p_1 \rangle K^+ | p_2 \rangle | (\bar{d}s)_V - A | 0 \rangle$ has a similar expression as Eq. (4.7)

$$\langle K^- | p_3 \rangle | (\bar{s}b)_V - A | B^- \rangle \langle \pi^- | p_1 \rangle K^+ | p_2 \rangle | (\bar{d}s)_V - A | 0 \rangle = - F^{B K}_1(s_{12}) F^{K \pi}_1(s_{12}) \left[ s_{13} - s_{23} - \frac{(m^2_B - m^2_K)(m^2_K - m^2_\pi)}{s_{12}} \right]$$

$$- F^{B K}_0(s_{12}) F^{K \pi}_0(s_{12}) \frac{(m^2_B - m^2_K)(m^2_K - m^2_\pi)}{s_{12}}.$$  \hspace{1cm} (5.3)

As in Eq. (4.5), the form factor $F^{K \pi}_1$ receives a resonant contribution for the $K^*$ pole. The nonresonant and various resonant contributions to $B^- \rightarrow K^+ K^- \pi^-$ are shown in Table VIII. The predicted total rate agrees well with experiment.

Note that no clear $\phi(1020)$ signature is observed in the mass region $m^2_{K^+ K^-}$ around 1 GeV$^2$. Indeed, the branching fraction of the two-body decay $B^- \rightarrow \phi \pi^-$ is expected to be very small, of order $4.3 \times 10^{-8}$. It is induced mainly from $B^- \rightarrow \omega \pi^-$ followed by a small $\omega - \phi$ mixing.

**B. $\bar{B}^0 \rightarrow K_S K^{\pm \pi^{\mp}}$ decay**

The factorizable $\bar{B}^0 \rightarrow K^{0} K^{\pm \pi^{\mp}}$ decay amplitude is given in Eq. (132). The calculated branching fraction $(6.2^{+2.7}_{-1.7}) \times 10^{-6}$ is in good agreement with the current average of BaBar [18] and LHCb [19], namely, $(6.4 \pm 0.8) \times 10^{-6}$. The resonant states $K^{* -}$ and $K^*_{0}^{+}$ (1430) are absent in this decay because the quasi two-body decays $\bar{B}^0 \rightarrow K^{\pm} K^{\mp}$ and $K^{\pm} K^*_{0}^{+}$ (1430) can proceed only through the $W$-exchange diagram and hence they are very suppressed.
TABLE VIII: Predicted branching fractions (in units of $10^{-6}$) of resonant and nonresonant (NR) contributions to $B^- \rightarrow K^+K^-\pi^-$ and $B^0 \rightarrow K_SK^{\pm}\pi^{\mp}$. Experimental results are taken from Table [1].

| Decay mode | Decay mode |
|------------|------------|
| $B^- \rightarrow K^+K^-\pi^-$ | |
| $K^{*0}K^-$ | $0.22^{+0.00+0.04+0.01}_{-0.00-0.04-0.01}$ |
| $f_0^*(980)\pi^-$ | $0.23^{+0.00+0.01+0.01}_{-0.00-0.01-0.01}$ |
| Total(theory) | $5.1^{+0.7+1.1+0.0}_{-0.8-0.7-0.0}$ |
| $B^0 \rightarrow K^0K^0\pi^\pm$ | |
| $K^{*0}K^{*0}$ | $0.20^{+0.00+0.04+0.00}_{-0.00-0.03-0.00}$ |
| NR | $4.2^{+0.7+1.9+0.1}_{-0.8-0.9-0.1}$ |
| Total(theory) | $6.2^{+0.7+2.6+0.1}_{-0.8-1.5-0.1}$ |
| Total(expt) | 6.4 ± 0.8 |

C. $B^0 \rightarrow K^+K^-\pi^0$ decay

The factorizable amplitude of $B^0 \rightarrow K^+K^-\pi^0$ can be found in Eq. (13). Since $\mathcal{B}(B^- \rightarrow K^+K^-\pi^-) = (5.0 \pm 0.7) \times 10^{-6}$ [10], it has been conjectured that the branching fraction of $B^0 \rightarrow K^+K^-\pi^0$ should be of order $2.5 \times 10^{-6}$, which is indeed very close to the Belle measurement $(2.17 \pm 0.65) \times 10^{-6}$ [24]. However, a detailed study indicates that $\mathcal{B}(B^0 \rightarrow K^+K^-\pi^0)$ is very small, of order $5 \times 10^{-8}$. This is mainly because the short-distance contribution to this mode is much smaller than the $K^+K^-\pi^-$ one because the latter is governed by the external pion-emission tree amplitude, while the former is dominated by the internal pion emission. As a result, $A(B^0 \rightarrow K^+K^-\pi^0)/A(B^- \rightarrow K^+K^-\pi^-) \approx a_2/(\sqrt{2}a_1)$. The experimental observation of a sizable rate for $K^+K^-\pi^0$ implies that this mode should receive dominant long-distance contributions. Since the branching fraction of $B^0 \rightarrow \pi^+\pi^-\pi^0$ is of order $20 \times 10^{-6}$ (see Table [IV]), it is tempting to consider a final state rescattering of $\pi^+\pi^-\pi^0$ into $K^+K^-$ that may substantially enhance the rate of $B^0 \rightarrow K^+K^-\pi^0$. To estimate the effect of $\pi^+\pi^- \rightarrow K^+K^-$ rescattering, we work in the framework of [55] and note that in the quasi-elastic rescattering in $B \rightarrow PP$ modes, the corresponding rescattering amplitude is governed by the so-called annihilation rescatterings. The $K^+K^-$ amplitude receives contributions from the $\pi^+\pi^-$ amplitude with a rescattering factor of $i(r_a^{1/2} + r_e^{1/2})$, where $r_a$ and $r_e$, respectively, correspond to annihilation and total-annihilation rescattering parameters (see Figs. 1(c), (d), Eqs. (8) and Eq. (10) of [55]). This factor is highly constrained by $B^0 \rightarrow K^+K^-$ rate and found to be 0.15 in magnitude and $-144^\circ$ in phase [55]. Consequently, the contribution to $K^+K^-\pi^0$ rate from $\pi^+\pi^-\pi^0$ rescattering is estimated to be $0.5 \times 10^{-6}$, which is too small to account for the observed rate. Of course, rescattering in three-body is not necessarily the same as the two-body one, but, in general, we do not expect a sizable change from the above estimation. Therefore, the unexpectedly large rate of $B^0 \rightarrow K^+K^-\pi^0$ still remains unexplained.
TABLE IX: Branching fractions (in units of $10^{-6}$) of quasi-two-body decays $B \to VP$ and $B \to SP$ obtained from the studies of three-body decays based on the factorization approach. Unless specified, the experimental results are obtained from the three-body Dalitz plot analyses given in previous Tables. Theoretical uncertainties have been added in quadrature. QCD factorization (QCDF) predictions taken from [36] for $VP$ modes and from [51] for $SP$ channels are shown here for comparison.

| Decay mode          | BaBar   | Belle   | QCDF    | This work |
|---------------------|---------|---------|---------|-----------|
| $\phi K^-$          | $9.2 \pm 0.4^{+0.7}_{-0.5}$ | $9.6 \pm 0.9^{+1.1}_{-0.8}$ | $8.8^{+2.8}_{-2.7}$ | $5.8^{+1.1}_{-1.0}$ |
| $\phi K^0$          | $7.1 \pm 0.6^{+0.4}_{-0.3}$ | $9.0^{+2.2}_{-1.8}$ | $8.1^{+2.6}_{-2.5}$ | $5.3^{+0.9}_{-0.8}$ |

| $\rho^0\pi^0$       | $8.1 \pm 0.7^{+0.3}_{-1.6}$ | $8.0^{+2.3}_{-2.0}$ | $8.7^{+2.7}_{-1.3}$ | $6.7^{+0.4}_{-0.4}$ |
| $\rho^0\pi^0$       | $22.6 \pm 1.8 \pm 2.2$ | $22.6 \pm 1.1 \pm 4.4$ | $25.1^{+1.5+1.4}_{-2.2-1.8}$ | $17.8^{+3.6}_{-3.2}$ |
| $\rho^0\pi^0$       | $1.4 \pm 0.6 \pm 0.3$ | $3.0 \pm 0.5 \pm 0.7$ | $1.3^{+0.6}_{-0.6}$ | $1.0^{+0.1}_{-0.1}$ |
| $f_0(980) K^-$; $f_0 \to \pi^+\pi^-$ | $10.3 \pm 0.5^{+2.0}_{-1.4}$ | $8.8 \pm 0.8^{+0.9}_{-1.8}$ | $8.1^{+1.0+1.5}_{-0.9}$ | $6.6^{+1.6}_{-1.3}$ |
| $f_0(980) K^0$; $f_0 \to \pi^+\pi^-$ | $6.9 \pm 0.8 \pm 0.6$ | $7.6 \pm 1.7^{+0.8}_{-0.9}$ | $7.4^{+0.9+1.4}_{-0.8}$ | $5.9^{+1.5}_{-1.6}$ |
| $f_0(980) K^0$; $f_0 \to K^+K^-$ | $9.4 \pm 1.6 \pm 2.8$ | $< 2.9$ | $11.0^{+2.6}_{-2.1}$ | $11.0^{+2.6}_{-2.1}$ |
| $f_0(980) K^0$; $f_0 \to K^+K^-$ | $7.0^{+2.6}_{-1.8}$ | $2.4$ | $9.1^{+1.7}_{-1.4}$ | $9.1^{+1.7}_{-1.4}$ |
| $f_0(980) \pi^0$; $f_0 \to \pi^+\pi^-$ | $< 1.5$ |              | $0.13^{+0.02+0.09}_{-0.02-0.06}$ | $0.20^{+0.01}_{-0.01}$ |
| $K^0(1430)\pi^-$ | $32.0 \pm 1.2^{+10.8}_{-6.0}$ | $51.6 \pm 1.7^{+7.0}_{-7.5}$ | $12.9^{+4.0}_{-3.7}$ | $18.3^{+8.1}_{-6.5}$ |
| $K^0(1430)\pi^0$ | $7.0 \pm 0.5 \pm 1.1$ |              | $5.6^{+2.6}_{-1.3}$ | $6.7^{+3.3}_{-2.7}$ |
| $K^0_\bar{0}(1430)\pi^+$ | $29.9^{+2.3}_{-1.7}$ | $3.6^{+6.8}_{-3.6}$ | $13.8^{+4.5}_{-3.6}$ | $16.7^{+7.3}_{-5.9}$ |

$^a$Not determined directly from the Dalitz plot analysis of three-body decays.

$^b$The BABAR measurement $B(B^- \to f_0(980) K^-; f_0(980) \to \pi^0\pi^0) = (2.8 \pm 0.6 \pm 0.3) \times 10^{-6}$ is not consistent with another BABAR result $B(B^- \to f_0(980) K^-; f_0(980) \to \pi^+\pi^-) = (10.3 \pm 0.5^{+2.0}_{-1.4}) \times 10^{-6}$ in view of the fact $B(f_0 \to \pi^+\pi^-) = 2B(f_0 \to \pi^0\pi^0)$.

$^c$We have assumed $B(f_0(980) \to \pi^+\pi^-) = 0.50$ for the QCDF calculation.

$^d$Another BABAR measurement of $B(B^- \to K^-\pi^+\pi^0)$ (see Table VI) leads to $B(B^- \to K^-\pi^-\pi^0) = 27.8 \pm 2.5 \pm 3.3$. 

25
VI. TWO-BODY $B \to VP$ AND $B \to SP$ DECAYS

So far we have considered the branching fraction products $B(B \to Rh_1)B(R \to h_2h_3)$ with the resonance $R$ being a vector meson or a scalar meson. Using the experimental information on $B(R \to h_2h_3)$ \cite{42}

\[ B(K^{*0} \to K^+\pi^-) = B(K^{*+} \to K^0\pi^+) = 2B(K^{*+} \to K^+\pi^0) = \frac{2}{3}, \]

\[ B(K_0^{*0}(1430) \to K^+\pi^-) = 2B(K_0^{*+}(1430) \to K^+\pi^0) = \frac{2}{3}(0.93 \pm 0.10), \]

$B(\phi \to K^+K^-) = 0.489 \pm 0.005$, \hspace{1cm} (6.1)

and applying the narrow width approximation \cite{36}, one can extract the branching fractions of $B \to VP$ and $B \to SP$. The results are summarized in Table \textbf{IX}. Except the channels $\rho^0\overline{K}^0$ from BaBar, $\phi K^0$, $\rho^0\pi^-$ from Belle, $\rho^0\pi^0$ and $\phi^+\pi^-$ from both BaBar and Belle, all the experimental results are obtained from the three-body Dalitz plot analyses shown in previous Tables.

We see that except for $\rho\tau$ and $f_0(980)K$ modes, the naive factorization predictions for penguin-dominated decays such as $B \to \phi K, K^*\pi, K_0^{*0}(1430)\pi$ are usually too small by a factor of 2–3 and further suppressed for $B \to \rho K$ when confronted with experiment. This calls for $1/m_b$ power corrections to solve the rate deficit problem. Within the framework of QCD factorization, we have considered two different types of power correction effects in order to resolve the $CP$ puzzles and rate deficit problems with penguin-dominated two-body decays of $B$ mesons and color-suppressed tree-dominated $\pi^0\pi^0$ and $\rho^0\pi^0$ modes: penguin annihilation and soft corrections to the color-suppressed tree amplitude \cite{36}. However, the consideration of these power corrections for three-body $B$ decays is beyond the scope of this work.

VII. DIRECT CP ASYMMETRIES

A. Inclusive CP asymmetries

Experimental measurements of direct $CP$ violation for various charmless three-body $B$ decays are collected in Table \textbf{II}. We notice that $CP$ asymmetries of the pair $\pi^-\pi^+\pi^-$ and $K^-K^+K^-$ are of opposite signs, and likewise for the pair $K^-\pi^+\pi^-$ and $\pi^-K^+K^-$. This can be understood in terms of $U$-spin symmetry. In the limit of $U$-spin symmetry, $\Delta S=0$ $B^-$ decays can be related to the $\Delta S=1$ one. For example,

\[ A(B^- \to \pi^-\pi^+\pi^-) = V_{ub}^*V_{ud}\langle\pi^-\pi^+\pi^-|O_d^n|B^-\rangle + V_{ub}^*V_{cd}\langle\pi^-\pi^+\pi^-|O_d^n|B^-\rangle, \]

\[ A(B^- \to K^-K^+K^-) = V_{ub}^*V_{us}\langle K^-K^+K^-|O_s^n|B^-\rangle + V_{ub}^*V_{cs}\langle K^-K^+K^-|O_s^n|B^-\rangle, \hspace{1cm} (7.1) \]

where the 4-quark operator $O_s$ is for the $b \to sq_1\bar{q}_2$ transition and $O_d$ for the $b \to dq_1\bar{q}_2$ transition. The assumption of $U$-spin symmetry implies that under $d \leftrightarrow s$ transitions

\[ \langle K^-K^+K^-|O_s^n|B^-\rangle = \langle \pi^-\pi^+\pi^-|O_d^n|B^-\rangle, \hspace{1cm} \langle K^-K^+K^-|O_s^n|B^-\rangle = \langle \pi^-\pi^+\pi^-|O_d^n|B^-\rangle, \hspace{1cm} (7.2) \]

which can be checked from Eqs. (2.4) and (3.1). Using the relation for the CKM matrix \cite{56}

\[ \text{Im}(V_{ub}^*V_{ud}V_{cd}^*) = -\text{Im}(V_{ub}^*V_{us}V_{cb}^*) \hspace{1cm}, \hspace{1cm} (7.3) \]
it is straightforward to show that
\[ |A(B^- \to K^-K^+K^-)|^2 - |A(B^+ \to K^+K^-K^+)|^2 = |A(B^- \to \pi^-\pi^+\pi^-)|^2 - |A(B^+ \to \pi^+\pi^-\pi^+)|^2. \] (7.4)

Hence, U-spin symmetry leads to the relation
\[ R_1 \equiv \frac{A_{CP}(B^- \to \pi^-\pi^+\pi^-)}{A_{CP}(B^- \to K^-K^+K^-)} = -\frac{\Gamma(B^- \to K^-K^+K^-)}{\Gamma(B^- \to \pi^-\pi^+\pi^-)}. \] (7.5)

Likewise,
\[ R_2 \equiv \frac{A_{CP}(B^- \to \pi^+K^-K^-)}{A_{CP}(B^- \to K^-\pi^+\pi^-)} = -\frac{\Gamma(B^- \to K^-\pi^+\pi^-)}{\Gamma(B^- \to K^-K^+K^-)}. \] (7.6)

The predicted signs of the ratios \( R_1 \) and \( R_2 \) are confirmed by experiment.

What is the relative sign between \( A_{CP}(B^- \to \pi^-K^-K^-) \) and \( A_{CP}(B^- \to \pi^-\pi^+\pi^-) \) ? Applying U-spin symmetry to two of the mesons in final states, one with positive charge and the other with negative charge, we obtain from Eqs. (2.4) and (5.1) that
\[ A(B^- \to \pi^-\pi^+\pi^+)_{p_1p_2p_3} = A(B^- \to \pi^-K^-K^+)_{p_1p_2p_3} + A(B^- \to \pi^-K^-K^+)_{p_2p_1p_3}, \] (7.7)

where the subscript \( p_1p_2p_3 \) denotes the momentum of the corresponding meson in order. Similarly,
\[ A(B^- \to K^-K^-K^+)_{p_1p_2p_3} = A(B^- \to K^-\pi^-\pi^+)_{p_1p_2p_3} + A(B^- \to K^-\pi^-\pi^+)_{p_2p_1p_3}. \] (7.8)

The above two relations agree with (5.8). Because of the momentum dependence of decay amplitudes, the \( CP \) rate difference in \( \pi^-\pi^-\pi^+ \) \((K^-K^-K^+)\) cannot be related to \( \pi^-K^-K^- (K^-\pi^-\pi^+) \). Therefore, U-spin or flavor SU(3) symmetry does not lead to any testable relations between \( A_{CP}(\pi^-K^-K^-) \) and \( A_{CP}(\pi^-\pi^+\pi^-) \) and between \( A_{CP}(\pi^-\pi^+\pi^-) \) and \( A_{CP}(K^-K^-K^-) \).

Although symmetry argument alone does not give hints at the relative sign of \( CP \) asymmetries in the pair of \( \Delta S = 0 \) and \( \Delta S = 1 \) decays, a realistic model calculation in the framework of this work shows a positive relative sign. When the unknown two-body matrix elements of scalar densities \( \langle K\pi|\bar{su}0\rangle \) such as \( \langle K^-\pi^+|\bar{s}d0\rangle \) and \( \langle K^-\pi^-|\bar{su}0\rangle \), \( \langle K^-\pi^0|\bar{u}d0\rangle \) and \( \langle K^-\pi^0|\bar{d}u0\rangle \) are related to \( \langle K^+K^-|\bar{s}s0\rangle \) via SU(3) symmetry, e.g.
\[ \langle K^-(p_1)\pi^+(p_2)|\bar{s}d0\rangle^{NR} = \langle K^+(p_1)K^-(p_2)|\bar{s}s0\rangle^{NR} = f_s^{NR}(s_{12}), \] (7.9)

with the expression of \( f_s^{NR} \) given in Eq. (3.11), we find \( A_{CP}(K^-\pi^+\pi^-) \approx -3.7\% \) and \( A_{CP}(K^+K^-\pi^-) \approx 13.1\% \). Hence, they are of the same sign as \( A_{CP}(K^-K^+K^-) \) and \( A_{CP}(\pi^+\pi^-\pi^-) \), respectively. However, the naive predictions are wrong in signs when confronted with the corresponding data, \((3.3\pm1.0)\%\) and \((-11.9\pm4.1)\%\). That is, the data in Table II indicate that \( CP \) asymmetries of the pair \( K^-K^+K^- \) and \( K^-\pi^+\pi^- \) are of similar magnitude but opposite in sign and likewise for the pair \( \pi^-K^-K^- \) and \( \pi^-\pi^+\pi^- \). They have the common feature that when \( K^+K^- \) is replaced by \( \pi^+\pi^- \), \( CP \) asymmetry is flipped in sign.

Recently, it has been conjectured that maybe the final rescattering between \( \pi^+\pi^- \) and \( K^+K^- \) in conjunction with \( CPT \) invariance is responsible for the sign change \[ 57, 59, 60. \] As stressed in [61], the presence of final-state interactions (FSIs) can have an interesting impact on the direct \( CP \) violation phenomenology. Long-distance final state rescattering effects, in general, will lead to a
different pattern of CP violation, namely, “compound” CP violation. Predictions of simple CP violation are quite distinct from that of compound CP violation. Moreover, the sign of CP asymmetry can be easily flipped by long-distance rescattering effects [61]. A well known example is the direct CP violation in $B^0 \rightarrow K^-\pi^+$. In the heavy quark limit, the decay amplitudes of charmless two-body decays of $B$ mesons can be described in terms of decay constants and form factors. However, the predicted direct CP-violating asymmetries for $B^0 \rightarrow K^-\pi^+$ and $\overline{B}^0_s \rightarrow K^+\pi^-$ disagree with experiment in signs [62]. This calls for the the necessity of going beyond the leading $1/m_b$ power expansion. Possible $1/m_b$ power corrections to QCD penguin amplitudes include long-distance charming penguins, final-state interactions and penguin annihilation. Because of possible “double counting” problems, one should not take into account all power correction effects simultaneously. It has been shown explicitly in [61] that FSIs can account for the sign flip of CP asymmetry and the rate deficit of $B^0 \rightarrow K^-\pi^+$. More precisely, the decays $B^0 \rightarrow D(s)^*(s)\rightarrow K^-\pi^+$ will give a sizable and negative long-distance contribution $A_{LD}^s$, so that the net CP asymmetry $A_{CP} = A_{SD} + A_{LD}^s$ is negative for $B^0 \rightarrow K^-\pi^+$ (for details, see [61]). In the QCD factorization approach [32], sign flip can be caused by penguin annihilation parameterized in terms of two unknown parameters $\rho_A$ and $\phi_A$.

It is known how to explicitly take into account the constraints from the CPT theorem when computing partial rate asymmetries for inclusive decays at the quark level [63, 64] (for a review, see [65]). However, the implication of the CPT theorem for CP asymmetries at the hadron level in exclusive or semi-inclusive reactions is more complicated and remains mostly unclear [66].

Taking the cue from the LHCb observation of $A_{CP}(\pi^-\pi^+\pi^-) \approx -A_{CP}(\pi^-K^+K^-)$ and $A_{CP}(K^-\pi^+\pi^-) \approx -A_{CP}(K^-K^+K^-)$, it is conceivable that final-state rescattering may play an important role for direct CP violation. In the absence of a detailed model of final-state interactions for the pair $B^- \rightarrow K^-\pi^+\pi^-$ and $\pi^-K^+K^-$, we shall assume that FSIs amount to giving a large strong phase $\delta$ to the nonresonant component of the matrix element of scalar density $(K^-\pi^+|\bar{s}d|0)$

$$
\langle K^-(p_1)\pi^+(p_2)|\bar{s}d|0\rangle^{NR} = \frac{v}{3} (3F_{NR} + 2F_{NR}') + \sigma_{NR} e^{-\alpha s_{12}} e^{i\delta}.
$$

(7.10)

Since CP violation arises from the interference between tree and penguin amplitudes and since nonresonant penguin contributions to the penguin-dominated decay $K^-\pi^+\pi^-$ are governed by the matrix element $\langle K^-\pi^+|\bar{s}d|0\rangle$, it is plausible that a strong phase in $\langle K^-\pi^+|\bar{s}d|0\rangle$ induced from FSIs might flip the sign of CP asymmetry. A fit to the data of $K^-\pi^+\pi^-$ yields

$$
\langle K^-(p_1)\pi^+(p_2)|\bar{s}d|0\rangle^{NR} \approx \frac{v}{3} (3F_{NR} + 2F_{NR}') + \sigma_{NR} e^{-\alpha s_{12}} e^{i\pi} \left(1 + 4 \frac{m_K^2 - m_{\pi}^2}{s_{12}}\right)
$$

(7.11)

with the parameter $\sigma_{NR}$ given in Eq. (3.13). It follows from U-spin symmetry that

$$
\langle K^+(p_1)\pi^-|\bar{s}s|0\rangle^{NR} \approx \frac{v}{3} (3F_{NR} + 2F_{NR}') + \sigma_{NR} e^{-\alpha s_{12}} e^{i\pi} \left(1 - 4 \frac{m_K^2 - m_{\pi}^2}{s_{12}}\right),
$$

(7.12)

which will be used to describe $B \rightarrow K\overline{K}\pi$ decays. Note that we have implicitly assumed that power corrections will not affect CP violation in $\pi^+\pi^-\pi^-$ and $K^+K^-K^-$. The major uncertainty with direct CP violation comes from the strong phases which are needed to induce partial rate CP asymmetries. In this work, the strong phases arise from the effective
TABLE X: Direct CP asymmetries (in %) for various charmless three-body B decays. Experimental results are taken from [6] and [72]. The mass regions for local CP asymmetries are specified in Eqs. (1.4)–(1.7).

Wilson coefficients $d_i^p$ listed in Eq. (2.3), the Breit-Wigner formalism for resonances and the penguin matrix elements of scalar densities. Since direct CP violation in charmless two-body decays can be significantly affected by final-state rescattering [61], it is natural to extend the study of final-state rescattering effects to the case of three-body B decays. We will leave this to a future investigation.

The calculated inclusive CP asymmetries $(8.7^{+1.7}_{-1.9})\%$ for $\pi^+\pi^-\pi^-$ and $(-7.1^{+2.4}_{-1.7})\%$ for $K^+K^-K^-$ (see Table X) are consistent with LHC measurements in both sign and magnitude (see Table I). As noted in passing, if we set $\delta = 0$ in Eq. (7.10) so that $\langle K^+\pi^-|\bar{d}s|0\rangle = \langle K^+K^-|\bar{s}s|0\rangle$, the predicted CP violation $A_{CP}(K^-\pi^+\pi^-) = (-3.8^{+1.2}_{-0.7})\%$ will be wrong in sign. If a strong phase $\delta$ is allowed due to some power corrections such as FSIs, we obtain $A_{CP}(K^-\pi^+\pi^-) = (2.6^{+1.6}_{-1.9})\%$ provided that the modified matrix element Eq. (7.11) is applied. Using Eq. (7.12) which follows from Eq. (7.11) via U-spin symmetry, we then predict $A_{CP}(K^+K^-\pi^-) = (-13.4^{+1.6}_{-1.8})\%$ in agreement with experiment.

Besides direct CP violation in $K^+K^-K^-, K^+K^-\pi^-, K^-\pi^+\pi^-,$ and especially $B^- \rightarrow K^0\pi^-\pi^0$ can have sizable asymmetries.
TABLE XI: Predicted direct \( CP \) asymmetries (in \%) due to nonresonant contributions to various charmless three-body charged \( B \) decays. The mass regions for local \( CP \) asymmetries are specified in Eqs. \([11]–[13]\). LHCb measurements \([1]–[3]\) are shown for comparison.

| \( ACP \) \((\rho) \) region \| \( \pi^-\pi^+\pi^- \) | \( K^-\pi^+\pi^- \) | \( K^+K^-\pi^- \) | \( K^+K^-K^- \) |

| \( \text{expt} \) | 58.4 \( \pm 8.7 \) | 67.8 \( \pm 8.5 \) | \(-64.8 \pm 7.2 \) | \(-22.6 \pm 2.2 \) |

B. Regional \( CP \) asymmetries

Large local \( CP \) asymmetries in three-body charged \( B \) decays have been observed by LHCb in the low mass regions specified in Eqs. \([11]–[13] \) \([1]–[3]\). If intermediate resonant states are not associated in these low mass regions, it is natural to expect that the Dalitz plot is governed by nonresonant contributions. In this case direct \( CP \) violation arises solely from the interference of tree and penguin nonresonant amplitudes. For example, in the absence of resonances, \( CP \) asymmetry in \( B^- \to K^-\pi^+\pi^- \) stems mainly from the interference of the nonresonant tree amplitude \( \langle \pi^+\pi^-|(|\bar{u}b)v_{-A}|B^-\rangle\langle K^-|(|\bar{s}u)v_{-A}|0\rangle \) and the nonresonant penguin amplitude \( \langle \pi^-|\bar{d}b|B^-\rangle\langle K^-\pi^+|\bar{s}d|0\rangle \). The results of the calculated local \( CP \) asymmetries are shown in Table XI. It is evident that except the mode \( K^+K^-\pi^- \), regional \( CP \) violation is indeed dominated by the nonresonant background.

A realistic and straightforward calculation of regional \( CP \) asymmetries in our model yields the results shown in Table XI. We see in this table that while regional \( CP \) violation of \( K^+K^-K^- \) agrees with experiment within errors, the predicted local asymmetries of order \(-19\%\), \(18\%\) and \(23\%\) for \( K^+K^-\pi^- \), \( K^-\pi^+\pi^- \) and \( \pi^+\pi^-\pi^- \), respectively, are indeed greatly enhanced with respect to the inclusive ones, though they are still significantly below the corresponding data of order \(-65\%\), \(68\%\) and \(58\%\). The reader may wonder why the realistic calculation yields results different from the naive expectation. We will come to this point later.

It has been claimed recently that the observed large localized \( CP \) violation in \( B^- \to \pi^+\pi^-\pi^- \) may result from the interference of a light scalar meson \( f_0(500) \) and the vector \( \rho(770) \) resonance \([57]–[67]\), even though the latter resonance is not covered in the low mass region \( m_{\pi^-\pi^-}^{low} < 0.4 \text{ GeV}^2 \). Let us first consider the vector meson resonance \( \rho \) in \( B^- \to \pi^+\pi^-\pi^- \) decay. As pointed out in Sec. II.A, the calculated \( B(B^- \to \rho^0\pi^-) = (6.8\pm 0.4) \times 10^{-6} \) is consistent with the world average \( (8.3^{+1.2}_{-1.3}) \times 10^{-6} \) \([6]\) within errors. Its \( CP \) asymmetry is found to be \( A_{CP}(\rho^0\pi^-) = 0.059^{+0.012}_{-0.010} \). At first sight, this seems to be in agreement in sign with the BaBar measurement \( 0.18 \pm 0.07^{+0.05}_{-0.15} \) \([8]\). However, theoretical predictions based on QCDF, pQCD and soft-collinear effective theory all lead to a negative \( CP \) asymmetry for \( B^+ \to \rho^0\pi^- \) (see Table XIII of \([20]\)). As shown explicitly in Table IV of \([20]\), within the framework of QCDF, the inclusion of \( 1/m_b \) power corrections to penguin annihilation is responsible for the sign flip of \( A_{CP}(\rho^0\pi^-) \) to a right one. The consideration of power corrections is however beyond the scope of this work based on a simple factorization approach.

As for the scalar resonance \( f_0(500) \), if we assume the form factor \( F_0^{Bar}(0) = 0.25 \) and take the mixing angle \( \theta = 20^\circ \) in Eq. \([3.16]\), we find the branching fraction of \( B^- \to f_0(500)\pi^- \) to be
order of $2.6 \times 10^{-6}$, but its $CP$ violation is very small, of order $-1\%$. In our model calculation, we find that the local asymmetry due to $\rho^0(770)$ and $f_0(500)$ resonances is $(A_{CP}^{\rho_{\pi^+\pi^-}})_{\rho_{\pi^+\pi^-}} \approx -0.02$. Of course, the magnitude and even the sign might get modified if the model is improved to yield a negative $CP$ violation for $B^+ \to \rho^0\pi^+$ as discussed above.

Even the low mass region $m_{\pi^+\pi^-}^{\text{low}} < 0.4$ GeV$^2$ is below the resonance $\rho^0(770)$, we find in our calculation $\rho^0(770)$ makes sizable contributions to the rate and $CP$ violation of $\pi^+\pi^-\pi^-$. Indeed, the fraction of nonresonant contribution to the total rate is found to be only 10%. Therefore, a reliable estimate of $CP$ violation in the local regions of the Dalitz plot needs to take into account the effects of nearby resonances. As remarked before, our simple factorization model perhaps does not produce the “right” $CP$ asymmetry of $B^- \to \rho^0\pi^-$, this may explain why our prediction of $A_{CP}^{\rho_{\pi^+\pi^-}}$ is below the LHCb measurement.

For the decay $B^- \to K^+K^-\pi^-$, the resonance $f_0(980)$ is in the low mass region $m_{KK}^{K^+K^-} < 1.5$ GeV$^2$, but it is not clear if the intermediate states $K^*(892)$ and $K^*_0(1430)$ are excluded. As a result, it is not surprising that the measured (and also the calculated) local asymmetry in this mode is very different from the one arising solely from the nonresonant contribution.

C. Comments on other works

$CP$ violation in three-body decays of the charged $B$ meson has been investigated in Ref. [57, 60, 67–69]. The authors of [57, 67] considered the possibility of having a large local $CP$ violation in $B^- \to \pi^+\pi^-\pi^-$ resulting from the interference of the resonances $f_0(500)$ and $\rho^0(770)$. A similar mechanism has been applied to the decay $B^- \to K^-\pi^+\pi^-$ [69]. Studies of flavor SU(3) symmetry imposed on the nonresonant decay amplitudes and its implication on $CP$ violation were elaborated on in [68]. In our work, we have taken into account both resonant and nonresonant amplitudes simultaneously and worked out their contributions to branching fractions and $CP$ violation in details. We found that even in the absence of $f_0(500)$ resonance, local $CP$ asymmetry in $\pi^+\pi^-\pi^-$ can already reach the level of 23% due to nonresonant and other resonant contributions. Moreover, the regional asymmetry induced solely by the nonresonant component can be as large as 57% in our calculation.

The strong coupling between $K^+K^-$ and $\pi^+\pi^-$ channels were studied in [60] to explain the observed asymmetries in $B^- \to K^-K^+K^-$ and $B^- \to K^-\pi^+\pi^-$. Just as the example of $B^0 \to K^-\pi^+$ whose $CP$ violation is originally predicted to have wrong sign in naive factorization and gets a correct sign after power corrections such as final-state interactions or penguin annihilation, are taken into account, it will be very interesting to see an explicit demonstration of the sign flip of $A_{CP}(K^-\pi^+\pi^-)$ and $A_{CP}(\pi^-K^+K^-)$ when the final-state rescattering of $\pi\pi \leftrightarrow K\overline{K}$ is turned on.

VIII. CONCLUSIONS

We have presented in this work a study of charmless three-body decays of $B$ mesons within the framework of a simple model based on the factorization approach. Our main results are:
• Dominant nonresonant contributions to tree-dominated three-body decays arise from the $b \to u$ tree transition which can be evaluated using heavy meson chiral perturbation theory valid in the soft meson limit. The momentum dependence of nonresonant $b \to u$ transition amplitudes is parameterized in an exponential form $e^{-\alpha_{NR} P \cdot (p_i + p_j)}$ so that the HMChPT results are recovered in the soft meson limit $p_i, p_j \to 0$. The parameter $\alpha_{NR}$ is fixed by the measured nonresonant rate in $B^- \to \pi^+ \pi^- \pi^-$. 

• A unique feature of hadronic $B \to KKK$ decays is that they are predominated by the nonresonant contributions with nonresonant fraction of order (70-90)%. It follows that nonresonant contributions to the penguin-dominated modes should also be dominated by the penguin mechanism. Hence, nonresonant signals must come mainly from the penguin amplitude governed by the matrix element of scalar densities $\langle M_1 M_2 | \bar{q}_1 q_2 | 0 \rangle$. We use the measurements of $B^0 \to K_SK_SK_S$ to constrain the nonresonant component of $\langle KK | \bar{s}s | 0 \rangle$.

• The branching fraction of nonresonant contributions is of order $(15 - 20) \times 10^{-6}$ in penguin-dominated decays $B^- \to K^+ K^- K^-$, $K^- \pi^+ \pi^-$ and of order $(3 - 5) \times 10^{-6}$ in tree-dominated decays $B^- \to \pi^+ \pi^- \pi^-$, $K^+ K^- \pi^-$. The nonresonant fraction is predicted to be around 60% in $B \to K \pi \pi$ decays.

• The intermediate vector meson contributions to three-body decays are identified through the vector current, while the scalar meson resonances are mainly associated with the scalar density. Both scalar and vector resonances can contribute to the three-body matrix element $\langle P_1 P_2 | J_\mu | B \rangle$.

• The $\pi^+ \pi^- \pi^0$ mode is predicted to have a rate larger than $\pi^+ \pi^- \pi^-$ even though the former involves a $\pi^0$ and has no identical particles in the final state. This is because while the latter is dominated by the $\rho^0$ pole, the former receives $\rho^\pm$ and $\rho^0$ resonant contributions.

• We have made predictions for the resonant and nonresonant contributions to $B^0 \to \pi^+ \pi^- \pi^0$, $K^0 \pi^0 \pi^0$, $K_SK_\pm \pi^\mp$ and $B^- \to K^0 \pi^- \pi^0$.

• We emphasize that the seemingly huge difference between BaBar and Belle for the nonresonant contributions to $B^- \to K^- \pi^+ \pi^-$ and $B^0 \to K^- \pi^+ \pi^0$ is now relieved when the nonresonant part of the LASS parametrization adapted by BaBar for the description of $K \pi S$-wave is added coherently to the phase-space nonresonant piece.

• The surprisingly large rate of $B^0 \to K^+ K^- \pi^0$ observed by Belle is bigger than the naive expectation by two orders of magnitude. It implies that this mode should be dominated by long-distance contributions. It may arise from the decay $B^0 \to \pi^+ \pi^- \pi^0$ followed by the final-state rescattering of $\pi^+ \pi^-$ into $K^+ K^-$. However, an estimation based on the two-body FSI model shows $B(B^0 \to K^+ K^- \pi^0) \leq 0.5 \times 10^{-6}$. Therefore, the unexpectedly large rate of $B^0 \to K^+ K^- \pi^0$ still remains unexplained.
Based on the factorization approach, we have computed the resonant contributions to three-body decays and determined the rates for the quasi-two-body decays $B \to VP$ and $B \to SP$. The predicted $\rho\pi$, $f_0(980)K$ and $f_0(980)\pi$ rates are consistent with experiment, while the calculated $\phi K$, $K^*\pi$, $\rho K$ and $K_0^*(1430)\pi$ are too small compared to the data.

While the calculated direct $CP$ asymmetries for $K^+K^-K^-$ and $\pi^+\pi^--\pi^-$ modes are in good agreement with experiment in both magnitude and sign, the predicted $CP$ asymmetries in $B^- \to \pi^-K^+K^-$ and $B^- \to K^-\pi^+\pi^-$ are wrong in signs when confronted with experiment. It has been conjectured recently that a possible resolution to this $CP$ puzzle relies on final-state rescattering of $\pi^+\pi^-$ and $K^+K^-$. Assuming a large strong phase associated with $\langle K\pi|\bar{q}q|0\rangle$ arising from some sort of power corrections, we fit it to the data of $K^-\pi^+\pi^-$ and get correct signs for both $\pi^-K^+K^-$ and $K^-\pi^+\pi^-$ modes. We predict some testable $CP$ violation in $B^0 \to K^+K^-\pi^0$ and $K^+K^-K_S$.

In this work, there are three sources of strong phases: effective Wilson coefficients, propagators of resonances and the matrix element of scalar density $\langle M_1M_2|\bar{q}_1q_2|0\rangle$.

In the low mass regions devoid of the known resonances, direct $CP$ violation is naively expected to be dominated by nonresonant contributions. We found that except the $K^+K^-\pi^-$ mode where resonances are not excluded in the local region, partial rate asymmetries due to the nonresonant background are fairly close to the LHCb measurements. However, realistic model calculations show that resonances near the localized region can make sizable contribution to the total rates and asymmetries. At any rate, we have shown that the regional $CP$ violation is indeed largely enhanced with respect to the inclusive one, though it is still significantly below the data.

Acknowledgments

We are grateful to Xiao-Gang He for useful discussion. This research was supported in part by the National Center for Theoretical Sciences and the National Science Council of R.O.C. under Grant Nos. NSC100-2112-M-001-009-MY3 and NSC100-2112-M-033-001-MY3.

Appendix A: Input parameters

Many of the input parameters for the decay constants of pseudoscalar and vector mesons and form factors for $B \to P,V$ transitions can be found in [36] where uncertainties in form factors are shown. The reader is referred to [51] for decay constants and form factors related to scalar mesons.

For the CKM matrix elements, we use the updated Wolfenstein parameters $A = 0.823$, $\lambda = 0.22457$, $\bar{\rho} = 0.1289$ and $\bar{\eta} = 0.348$ [70]. The corresponding CKM angles are $\sin 2\beta = 0.689 \pm 0.019$.
and $\gamma = (69.7^{+1.3}_{-2.8})^0 \sqrt{70}$. For the running quark masses we shall use \[71\]

$$
\begin{align*}
m_b(m_b) &= 4.2\text{ GeV}, & m_b(2.1\text{ GeV}) &= 4.94\text{ GeV}, & m_b(1\text{ GeV}) &= 6.34\text{ GeV}, \\
m_c(m_b) &= 0.91\text{ GeV}, & m_c(2.1\text{ GeV}) &= 1.06\text{ GeV}, & m_c(1\text{ GeV}) &= 1.32\text{ GeV}, \\
m_s(2.1\text{ GeV}) &= 95\text{ MeV}, & m_s(1\text{ GeV}) &= 118\text{ MeV}, \\
m_d(2.1\text{ GeV}) &= 5.0\text{ MeV}, & m_u(2.1\text{ GeV}) &= 2.2\text{ MeV}.
\end{align*}
$$

(A1)

Among the quarks, the strange quark gives the major theoretical uncertainty to the decay amplitude. Hence, we will only consider the uncertainty in the strange quark mass given by $m_s(2.1\text{ GeV}) = 95 \pm 5\text{ MeV}$.  

**Appendix B: Decay amplitudes of $B \rightarrow PPP$ decays**

Most of the factorizable decay amplitudes of $\Delta S = 0$ and $\Delta S = 1$ three-body decays $B$ mesons are already collected in Appendix A of \[31\]. In this work, we have shown the factorizable decay amplitudes of $B^- \rightarrow K^+K^-\pi^-, K^-K^+\pi^-, K^-\pi^+\pi^-\pi^-\pi^+$ for the purpose of discussion and for corrections. In the following we write down the factorizable amplitudes of $B^- \rightarrow K^-\pi^0\pi^0$ and $B^0 \rightarrow K_SK^+\pi^-, K^+K^-\pi^-$:

$$
\langle K^-\pi^0\pi^0|T_p|B^-\rangle = \langle \pi^0\pi^0|(\bar{u}b)_{V-A}|B^-\rangle\langle K^-|((\bar{s}u)_{V-A}|0) \left[ a_1\delta_{pu} + a_4 + a_{10} - (a_6 + a_8)r_X^K \right] \\
+ \langle K^-\pi^0|((\bar{s}b)_{V-A}|B^-)\langle \pi^0|((\bar{u}u)_{V-A}|0) \left[ a_2\delta_{pu} + \frac{3}{2}(-a_7 + a_9) \right] \\
+ \langle K^-|((\bar{s}b)_{V-A}|B^-)\langle \pi^0\pi^0|((\bar{u}u)_{V-A}|0) \left[ 2a_2\delta_{pu} + a_3 + a_5 + a_7 + a_9 \right] \\
+ \langle K^-|((\bar{s}b)_{V-A}|B^-)\langle \pi^0\pi^0|((\bar{u}d)_{V-A}|0) \left[ a_3 + a_5 - \frac{1}{2}(a_7 + a_9) \right] \\
+ \langle K^-|((\bar{s}b)_{V-A}|B^-)\langle \pi^0\pi^0|((\bar{s}s)_{V-A}|0) \left[ a_3 + a_4 + a_5 - \frac{1}{2}(a_7 + a_9 + a_{10}) \right] \\
+ \langle K^-|\bar{s}b|B^-\rangle\langle \pi^0\pi^0|\bar{s}s|0\rangle (-2a_6^p + a_8^p) \\
+ \langle \pi^0|((\bar{u}b)_{V-A}|B^-)\langle K^-\pi^0|((\bar{s}u)_{V-A}|0) \left( a_4 + a_{10} \right) \\
+ \langle \pi^0|((\bar{u}b)_{V-A}|B^-)\langle K^-\pi^0|\bar{s}u|0\rangle (-2a_6^p - 2a_8^p) \\
+ \langle K^-\pi^0\pi^0|((\bar{s}u)_{V-A}|0)\langle (\bar{u}b)_{V-A}|B^-\rangle (a_1\delta_{pu} + a_4 + a_{10}) \\
+ \langle K^-\pi^0\pi^0|\bar{s}(1 + \gamma_5\bar{u})u|0\rangle\langle (\bar{u}\gamma_5\bar{b})_{V-A}|B^-\rangle (2a_6^p + 2a_8^p),
\end{align*}
$$

\begin{align*}
\langle K^0 K^\mp\pi^\pm|T_p|B^0\rangle &= \langle K^+\bar{T}^0|((\bar{u}b)_{V-A}|B^0)\langle \pi^-|((\bar{d}u)_{V-A}|0) \left[ a_1\delta_{pu} + a_4 + a_{10} - (a_6 + a_8)r_X^\pi \right] \\
+ \langle \pi^-|((\bar{u}b)_{V-A}|B^0)\langle K^-\pi^0|((\bar{d}u)_{V-A}|0) \left( a_1\delta_{pu} + a_4 + a_{10} \right) \\
+ \langle K^-\pi^-|((\bar{s}b)_{V-A}|B^0)\langle K^0|((\bar{d}s)_{V-A}|0) \left[ a_4 - \frac{1}{2}a_{10} - (a_6 - \frac{1}{2}a_8)r_X^K \right] \\
+ \langle \bar{T}^0|((\bar{s}b)_{V-A}|B^0)\langle K^-\pi^-|((\bar{d}s)_{V-A}|0) \left( a_4 - \frac{1}{2}a_{10} \right) \\
+ \langle \pi^-|\bar{u}b|B^0\rangle\langle K^-\pi^-|\bar{d}u|0\rangle (-2a_6^p - 2a_8^p).
\end{align*}

34
\[ + \langle K^0 | s| B^0 \rangle \langle K^+ \pi^- | d\bar{s} | 0 \rangle (-2a_6^0 + a_8^0) \]
\[ + \langle K^0 | K^+ | (\bar{u}u)_{V-A} | 0 \rangle \langle 0 | (\bar{d}b)_{V-A} | B^0 \rangle \left( a_2 \delta_{pu} + a_3 + a_5 + a_7 + a_9 \right) \]
\[ + \langle K^0 | K^+ | d(1 + \gamma_5) d | 0 \rangle \langle 0 | d\bar{\gamma}_5 b | B^0 \rangle (2a_6^0 - a_8^0), \]  
(B2)

\[ \langle \pi^0 K^+ K^- | T_{pu} | B^0 \rangle = \langle \pi^0 | (\bar{d}b)_{V-A} | B^0 \rangle \langle K^+ K^- | (\bar{u}u)_{V-A} | 0 \rangle \left( a_2 \delta_{pu} + a_3 + a_5 + a_7 + a_9 \right) \]
\[ + \langle \pi^0 | (\bar{d}b)_{V-A} | B^0 \rangle \langle K^+ K^- | d\bar{d} | 0 \rangle (-2a_6^0 + a_8^0) \]
\[ + \langle \pi^0 | (\bar{d}b)_{V-A} | B^0 \rangle \langle K^+ K^- | (\bar{s}s)_{V-A} | 0 \rangle \left[ a_3 + a_5 - \frac{1}{2}(a_7 + a_9) \right] \]
\[ + \langle K^+ K^- \pi^0 | (\bar{u}u)_{V-A} | 0 \rangle \langle 0 | (\bar{d}b)_{V-A} | B^0 \rangle \left( a_2 \delta_{pu} + a_4^0 + a_{10}^0 \right) \]
\[ + \langle K^+ K^- \pi^0 | d\bar{\gamma}_5 d | 0 \rangle \langle 0 | d\bar{\gamma}_5 b | B^0 \rangle (2a_6^0 - a_8^0). \]
