**Abstract** Complete malarial therapy depends largely on the immunological and inflammatory response of the host to the invading potentials of malarial parasite. In this study, we evaluated the roles of betulinic acid on immunological response, anti-inflammatory potentials, cardiac and skeletal muscle tissue damage in mice infected with chloroquine susceptible (NK 65) and resistant (ANKA) strains of *Plasmodium berghei*. Serum Interleukins 1β and 6 (IL-1β, IL-6), tumour necrosis factor alpha (TNF-α), immunoglobulins G and M (IgG and IgM), C-reactive protein (CRP) and creatine kinase (CK) were determined using ELISA technique. Aspartate aminotransferase (AST), alanine aminotransferase (ALT) and gamma glutamyl transferase (GGT) were determined using ELISA technique. The results showed that betulinic acid decreased the levels of IL-1β, IL-6, TNF-α and CRP relative to the infected control. The IgG and IgM levels significantly increased in both models while CK did not decrease significantly in both models although serum AST, ALT and GGT significantly decreased compared to the infected control. These results showed that betulinic acid possessed anti-inflammatory, immunomodulatory and remediating effects on tissue damage. Furthermore, the decrease in activity of CK brought about by betulinic acid is indicative of decrease in cardiac and skeletal muscle injury which is a major pathological concern in *Plasmodium* infection and treatment.

**Introduction**

The pathophysiology and lethal effects of human *Plasmodium* infection have been adjudged to be a consequence of imbalance between the pro- and anti-inflammatory cytokines in the system (Dunst et al. 2009). It is well established that *Plasmodium* infection causes a systemic human disease with clinical and biomedical similarities to other infectious diseases such as bacterial and viral diseases (Mohan et al. 2008). Furthermore, common symptoms such as loss of appetite, tiredness, aching joints and muscles, fever and sleepiness associated with systemic infection also accompany *Plasmodium vivax* and *Plasmodium falciparum* infections. To protect the cellular contents of the host, *Plasmodium* infection elicits immune response via the secretion of cytokines by the specific cells...
of immune system. They are signaling molecules that mediate and regulate inflammation. There are both pro-inflammatory and anti-inflammatory cytokines and some of them are pleiotrophic in functions (Zhang and An 2007). Both inflammatory and immunological response initiation to *Plasmodium* infection lead to malarial disease symptoms and the initial inflammatory symptoms alleviates infection. However, during *Plasmodium* infection, leucocytes, lymphocytes, monocytes and phagocytes are activated to secret inflammatory mediators that accelerate detectable parasite infection (Mavondo et al. 2019).

Endogenous cytokines such as tumour necrosis factor alpha (TNF-α), interleukin 1beta (IL-1β) and interleukin 6 (IL-6) are pro-inflammatory cytokines released as a consequent effect to the cytosolic presence of pathogen-associated molecular patterns (PAMPs) such as glycosyl phosphatidyl inositol (GPI) moieties that are attached to the antigens at the exterior portion of malarial parasites or may be found free in solution (Schofield, and Hackett 1993). The GPI moieties induce elevated levels of TNF-α and IL-1β causing increase in body temperature (Schofield, and Hackett 1993; Tachado et al. 1996). Apart from the GPI, malarial pigment, otherwise known as hemozoin also raise the levels of the pro-inflammatory cytokines (Ochiel et al. 2005; Keller et al. 2006a; b; Giusti et al. 2011). Malarial inflammatory response in the host heralds the onset of the pathophysiology of malaria, thus indicating that malarial treatment should be directed towards parasite clearance and disease. The C-reactive protein (CRP) is a pentameric, ring-shaped protein found in the blood plasma and its circulating concentrations rise in response to inflammation (Thompson et al. 1999; Sproston and Ashworth 2019). It is a protein of hepatic origin that increases as a result of IL-6 secretion by macrophages and T cells (Thompson et al. 1999). Several cases of skeletal muscle necrosis as a result of *Plasmodium* infection have been reported (Mishra and Newton 2009; Marrelli and Broto 2016). There are biomarkers that can link injured skeletal muscles with *Plasmodium* infection. Significant deviation from the normal serum levels of creatine kinase has been reported in malarial patients with severe muscle injury (Miller et al. 1989; Davis et al. 2000). Creatine kinase is an enzyme protein, predominantly found in cells of cardiac and skeletal muscles and it is involved in the synthesis and use of energy providing molecules. Although, chloroquine is used in the treatment of malaria, it has been reported that its prolonged use can cause heart blockage and progressive myopathy (Verlinden et al. 2016). Malarial phytotherapy is both anti-parasitic and anti-disease. The antiplasmodial activities of phytochemicals such as limonoid (Braga et al. 2020), Asiatic acid (Mavondo et al. 2016), friedelan-3-one (Noungoue et al. 2009) and betulinic acid (Egbubine et al. 2020) have been established. Although, betulinic acid, a plant triterpene has antiplasmodial effects against both chloroquine-sensitive and resistant strains of *Plasmodium* species, its effects in modulating the activities of inflammatory cytokines, immunoglobulins, creatine kinase and ability to alleviate the toxicity of some antimalarial drugs in different strains of malaria parasites’ infection is yet to be reported. It is in this regard that we investigated the immunomodulatory potentials of betulinic acid as an alternative in malarial therapy having previously presented evidence on the betulinic acid as an active antimalarial natural product, purified from *Alstonia boonie* (Olanlokun et al. 2021).

### Materials and methods

#### Preparation of betulinic acid

Betulinic acid was purified from the stem bark of *Alstonia boonie* and its purity was established by comparing the spectroscopic data (13C, 1H, COSY, HMBC, HSQC and DEPT) obtained with others previously observed from other plants and there was similarity in these data (Uddin et al. 2011). It was thereafter kept in the refrigerator until used.

#### Experimental animals and infection with parasites and treatment

Fifty male Swiss mice (18 ± 3 g) were obtained from the animal house section of Malaria Unit, Institute of Advanced Medical Research and Training, College of Medicine, University of Ibadan. They were acclimatized for one week and equally divided into two sets for susceptible and resistant model experiments. Twenty of the first twenty-five mice were infected with chloroquine sensitive (NK 65) strain of *Plasmodium berghei* with infected erythrocytes from a donor mouse (107 inoculum). Parasitemia was confirmed by microscopy after 72 h and they were divided into four groups (n = 5). Group I is the uninfected animals designated as normal control (treated with 10 ml/kg distilled water), group II which is the infected control was treated with the vehicle (10 ml/kg of 5%v/v DMSO), and group III was treated with standard drug, coartem (10 mg/kg). Graded doses of betulinic acid (12.5 and 25 mg/kg) were used to treat groups IV and V. The animals were treated for 7 days and parasitemia was determined by microscopy at two days interval. The research protocol for chloroquine resistant model looked more like the susceptible one except that the animals were infected with infected erythrocytes (ANKA) from a donor mouse, treatment lasted for 5 consecutive days, parasitemia was assessed daily and mefloquine was used as the standard.
drug (Ryley and Peters 1970). Dimethylsulfoxide (5% DMSO) was used to dissolve betulinic acid as observed in previous study (Worthley and Schott 1969; Rad et al. 2015). This study was carried out according to the Principle of Laboratory Animal Care and approved by University of Ibadan Animal Care and Use Research Ethics Committee (UI-ACUREC/19/0045).

Biochemical assays

Assay of serum IL-1β and IL-6

ELISA kits for IL-1β and IL-6, obtained from Elabscience, USA were used to assay for serum IL-1β and IL-6 by strictly following the manufacturer’s protocol using DNM-9602 A microplate reader.

Determination of tumour necrosis factor alpha and C-reactive protein

Serum levels of TNF-α and CRP were determined by using ELISA assay kits from Elabscience, USA by following the manufacturer’s protocol using a microplate reader.

Immunoglobulins (IgG and IgM) assays

Assays of relevant immunoglobulins (IgG and IgM) to malarial study were carried out using mouse immune-turbidimetric assay kits (Fortress Diagnostics, Antrim, UK) by following the manufacturer’s assay protocols.

Creatine kinase activity

Extent of tissue injury in Plasmodium infection and modulatory effect of betulinic acid was assessed via the determination of serum creatine kinase activity. This was done using ELISA assay kit (Elabscience, USA).

Serum AST, ALT and GGT assay

Serum aspartate and alanine aminotransferases (AST and ALT, respectively) activities were determined by using ELISA assay kits (from MTD diagnostics, Italy), and gamma glutamyl transferase (GGT) activity was determined by using ELISA assay kits (Fortress diagnostics, UK) strictly following the manufacturer’s protocol.

Statistical analysis

Data were analysed using descriptive statistics on duplicates (mean ± standard deviation). They were further analysed by comparing the normal control data with test groups using one-way analysis of variance. Graphpad prism (7.0 version) was used and Tukey’s comparison method was used to compare means among columns.

Results

Betulinic acid modulates IL-1β and IL-6 in both models of Plasmodium infection

Figure 1 shows the structure of betulinic acid while the influence of betulinic acid on the levels of serum IL-1β and IL-6 in mice infected with chloroquine susceptible and resistant strains of Plasmodium berghei are presented in Fig. 2. Here, we used different models of parasite strain since there is variation in the potency of drugs based on the parasite strain and to see if this would bring about variation in interleukin levels in response to betulinic acid intervention. Our results show that there was a significant \( P < 0.0001 \) increase in IL-1β levels in the infected controls of both models (Fig. 2a) compared to the normal control. Although, IL-1β levels in betulinic acid-treated mice in both models significantly increased compared with the normal control including the standard drug (coartem) in the susceptible model, treatment with 12.5 mg/kg in the susceptible model significantly decreased IL-1β levels to a level that is not statistically significant from the normal control (Fig. 2b).

It is interesting to note also that, contrary to a decrease in the level of IL-1β observed in both susceptible and resistant models, betulinic acid increased IL-6 levels in both models in a dose-dependent manner. It was however, observed that indeed, administration of betulinic acid caused an increase in the level of IL-6 in mice treated with betulinic acid (25 mg/kg) significantly \( (P < 0.001) \) higher than the infected control (Fig. 2d) while there was no such significant difference in the resistant model (Fig. 2c).
Betulinic acid decreases TNF-α and CRP in *Plasmodium berghei* models of malaria

The effect of betulinic acid administration on TNF-α and CRP levels in *Plasmodium berghei*-infected mice is presented in Fig. 3. *Plasmodium* infection significantly (*P < 0.0001*) increased TNF-α levels in both models as observed in the sera of the mice in the infected control group compared with the normal control (Fig. 3a, b). It is however, interesting to note that treatment with betulinic acid flattens the curve by significantly decreasing the levels of TNF-α in both models. Furthermore, when compared with the standard drug, betulinic acid (12.5 mg/kg) significantly (*P < 0.05*) decreased TNF-α when compared with mefloquine (Fig. 3a). Similar results were obtained in the susceptible model where betulinic acid (12.5 mg/kg) significantly (*P < 0.05*) decreased the level of TNF-α compared with coartem, the standard drug (Fig. 3b). Serum CRP level in the infected mice that were not treated, significantly increased in the resistant (*P < 0.05*) and susceptible (*P < 0.01*) models (Fig. 3c, d, respectively). In both models, CRP levels in infected animals that were treated with betulinic acid did not vary significantly when compared with the normal control. Although, CRP levels in mice treated with graded doses of betulinic acid did not vary significantly when compared with the standard drug control in the resistant model (Fig. 3c), there was a significant (*P < 0.01*) increase in serum CRP level of mice treated with betulinic acid (12.5 mg/kg) compared with the drug (coartem) control while the 25 mg/kg dose did not have any significant increase when compared with the drug control (Fig. 3d).

Betulinic acid stimulates immune response via IgG and IgM upregulation

Given that stimulation of the immune response is a critical factor in malarial parasite clearance from the host cells and as an underlying clinical immunity to malaria, serum total IgG and IgM levels in mice infected with malarial parasites (susceptible and resistant) but treated with betulinic acid were determined. Results show that *Plasmodium* infection significantly (*P < 0.001 and *P < 0.01*) lowered serum levels of IgG in both models, respectively. However, betulinic acid significantly increased IgG level in the resistant (*P < 0.01*) and the susceptible (*P < 0.05*) models (Fig. 4a, b). In this study, significant difference between the IgM levels in the normal mice that was not infected
with malarial parasite and the infected control were not observed. Furthermore, betulinic acid increased \((P < 0.05)\) IgM level in the susceptible model (Fig. 4c) while there was no significant change \((P > 0.05)\) in the serum level of IgM in the resistant model (Fig. 4d). It is interesting to note also that while IgG level of the infected control decreased significantly in both models (Fig. 4a, b), an increase in IgM antibody level of the infected control in both models of \(Plasmodium\) infection were observed (Fig. 4c, d).

**Betulinic acid decreases creatine kinase activity and some marker enzymes**

The activities of creatine kinase (CK), gamma glutamyl transferase (GGT), aspartate and alanine amino transferases (AST and ALT, respectively) were determined in order to ascertain the extent of the effects of \(Plasmodium\) infection on skeletal or cardiac muscle damage and toxicity of the administered dose of betulinic acid on liver tissue. Our results show that although, there was no significant difference in CK levels of the normal and infected controls, betulinic acid \((12.5\text{ mg/kg})\) significantly \((P < 0.05)\) decreased CK level in infected mice treated with betulinic acid in the resistant model (Fig. 5a). Although insignificantly \((P > 0.05)\), betulinic acid decreased CK level in the susceptible model (Fig. 5b). Liver damage was observed sequel to significant increase in AST (Fig. 5c, d), ALT (Fig. 5e, f) and GGT (Fig. 5g, h) observed in both models. Significantly too, betulinic acid decreased the activities of these enzymes.

**Discussion**

The infection by susceptible and resistant types of \(Plasmodium\) malaria have been discovered to be accompanied by inflammation (Clark et al. 2006). This disease has been treated with some drugs and promising phytochemicals such as friedelan-3-one and betulinic acid have been used for the treatment of this deadly infectious disease. Cytokines such as tumour necrosis factor alpha (TNF-\(\alpha\)) and interleukins are essential mechanisms for systemic
disease of which malaria is paramount (Clark et al. 2006). Although, regulated release of these mediators have been linked with protective effects and inhibition of parasite growth, extensive release of inflammatory cytokines has been linked with pathological conditions in systemic diseases including Plasmodium infection. It is in this regard that we investigated the regulatory role of betulinic acid on inflammatory cytokines and the possible link of its administration to immunomodulatory potentials in malarial treatment using mouse models.

Interleukins (IL-1\(\beta\) and IL-6, in this study) belong to the pro-inflammatory cytokines that are involved in the process of pathological pain. IL-1\(\beta\) are released by the monocytes and macrophages during infection and inflammation (Zhang and An 2007). Interleukin 1\(\beta\) has been observed to increase during blood stage infection by malarial parasites and correlates with disease severity but are expected to decrease after a successful intervention (Lyke et al. 2004). Therefore, a significant decrease in the levels of IL-1\(\beta\) after intervention with betulinic acid indicated a positive response to betulinic acid consequently leading to a decrease in GPI level, a significant inducer of pro-inflammatory cytokines.

In this study, the administration of betulinic acid increased interleukin 6 levels. Interleukin 6 is a pleiotropic interleukin that serves both as pro-inflammatory and also as an anti-inflammatory myokine depending on its serum level. As a pleiotropic cytokine, it plays a central role in host defense because of its immune and hematopoietic properties. Furthermore, evidence from human and animal studies showed that IL-6 contributes to host defense through the stimulation of acute phase responses, hematopoiesis and immune reactions (Tanaka et al. 2014). Furthermore, an increase in the expression and administration of IL-6 is linked with an increase in circulating platelet count (Kaser et al. 2001), an important factor needed in malarial treatment because thrombocytopenia occurs in malaria-infected patients (Kotepui et al. 2014).

Cytokines such as interleukins and tumor necrosis factor alpha (TNF-\(\alpha\)) perform mechanistic roles in systemic diseases caused by infectious organisms. Previous studies have shown that TNF-\(\alpha\) acts as homeostatic agent that its excessive production can cause disease condition. In this study, betulinic acid significantly decreased the production of TNF-\(\alpha\) relative to control. Malarial product such as glycosylphosphatidyl inositol is known to induce TNF-\(\alpha\)
production which at lower concentration inhibits malarial parasite growth but at higher concentrations induce inflammation (Clark 1987). In this study, betulinic acid significantly reduced the TNF-$\alpha$ levels to the minimum concentration which can be beneficial to the host. High levels of TNF-$\alpha$ is an indication that an individual is susceptible to cerebral malaria (McGuire et al. 1994).

The C-reactive protein (CRP) is an important marker of the severity of Plasmodium infection. Previous studies have shown that serum CRP levels is directly proportional to parasite load and complications in malaria and it is a useful marker of malarial severity and inflammation (Hurt et al. 1994; Paul et al. 2004). Interestingly, betulinic acid administration significantly decreased the level of CRP in both models of Plasmodium infection. Plasmodium parasites impair and evade the immune system of the host, preventing them from eliciting immune response during infection and this may explain why malarial patients are often susceptible to other infections and fail to respond to several vaccine treatments (Orjih and Nussenzweig 1979; Pietri et al. 2015; Belachew 2018). Protection against malaria is caused by an increase in serum immunoglobulin G (IgG) levels as a form of acquired immunity (Doolan et al. 2009). Similarly, serum IgM levels significantly increased in the resistant model while there was also an insignificant increase in the susceptible model when mouse malaria was treated with betulinic acid. Previous study has shown that maintenance of IgM response to malaria may have an important role in immunity both for the primary infection and subsequent infections (Boyle et al. 2019). We conclude therefore, that IgG and IgM responses are important contributors to naturally-acquired immunity against malaria.

There is evidence that critical skeletal muscle damage occur in Plasmodium infection (Davies et al. 1999). During this period, serum enzymes such as lactate dehydrogenase, aspartate aminotransferase, alanine aminotransferase and creatine kinase levels are significantly increased. These changes in the levels of these enzymes depend on the severity of the muscle disease and the applied therapy. Circulating creatine kinase increases in severe malaria and it is an important factor in fatal falciparum malaria (Ehrhardt et al. 2004). Moreover, some antimalarial drugs have been discovered to have deleterious effects on cardiac and skeletal muscle. Chloroquine (Ikezoe et al. 2009), quinine (Silamut et al. 1995) and artesunate (Tan et al. 2014) caused cardiomyopathy, ventricular fibrillation and proliferation of airway smooth muscle cells in humans, respectively. Apart from multidrug resistance and monotherapy inefficiencies, these are potential reasons for the rejection of these drugs as antimalarials. Interestingly, betulinic acid caused significant decrease in total creatine kinase, a critical index in muscle damage caused by malarial infection. Plasmodium infection is associated with significant increase in the serum levels of aspartate and alanine aminotransferases (Al-Salahy et al. 2016), showing that

![Fig. 5](image-url)
**Plasmodium** infection at the pre-erythrocytic stage causes liver injury. In this study, serum levels of these enzymes increased in both models in the infected controls. Although, artemether-lumefantrine is a drug of choice for clinical cure of multidrug Plasmodium infection, it causes significant liver enzyme abnormalities in aspartate and alanine aminotransferases, though asymptomatic (Pinto et al. 2017). Treatment of susceptible and resistant malaria with betulinic acid in mouse model significantly decreased the serum levels of these aminotransferases. Gamma glutamyl transferase (GGT) is a liver membranous enzyme as alkaline phosphatase is (Jarikre et al. 2001). The positive correlation between Plasmodium infection and serum increase in GGT level was mitigated significantly by betulinic acid in both models.

In summary, this study has shown that in addition to its antimalarial properties, betulinic acid possesses immunomodulatory and anti-inflammatory potentials needed in the treatment of infectious disease such as malaria by lowering the levels of the pro-inflammatory cytokines. Furthermore, responses in IgG and IgM levels are important factors in naturally acquired immunity to malaria and the doses administered in this study does not have toxic effects but rather reduced the serum levels of AST, ALT and GGT which are indicators of liver toxicity.

**Author contributions** JOO conceived this research idea, purified betulinic acid, performed data analysis and wrote the draft manuscript; POO treated the animals and performed assays; OOO read and corrected the manuscript. All authors read and approved the manuscript.

**Funding** The authors are the financiers of this study.

**Declarations**

**Conflict of interest** The authors declare that no conflict of interest exists.

**Ethics approval** All experiments were performed in accordance with the National Institute of Health guide for the care and use of laboratory animals (NIH Publications No. 8023, revised 1978). All protocols with respect to the care and use of experimental animals as laid down by the institute’s guide were strictly followed. Furthermore, ethical approval for this study was obtained from the University of Ibadan Animal Care & Use Research Ethics Committee (ACUREC).

**Consent for publication** All authors approved the manuscript for publication.
