EL-LABELINGS, SUPERSOLVABILITY AND 0-HECKE ALGEBRA ACTIONS ON POSETS

PETER MCNAMARA

Abstract. It is well known that if a finite graded lattice of rank \( n \) is supersolvable, then it has an EL-labeling where the labels along any maximal chain form a permutation. We call such a labeling an \( S_n \) EL-labeling and we show that a finite graded lattice of rank \( n \) is supersolvable if and only if it has such a labeling. We next consider finite graded posets of rank \( n \) with \( 0 \) and \( \hat{1} \) that have an \( S_n \) EL-labeling. We describe a type \( A \) 0-Hecke algebra action on the maximal chains of such posets. This action is local and gives a representation of these Hecke algebras whose character has characteristic that is closely related to Ehrenborg’s flag quasisymmetric function. We ask what other classes of posets have such an action and in particular we show that finite graded lattices of rank \( n \) have such an action if and only if they have an \( S_n \) EL-labeling.

1. Introduction

Supersolvable lattices were introduced by R. Stanley in [16] where he showed that the covering relations can be labeled by the integers to give an EL-labeling. We explain and discuss these terms in Section 2. In fact, this EL-labeling of a supersolvable lattice of rank \( n \) is seen to have the additional property that the labels along any maximal chain of the lattice form a permutation of \( 1, 2, \ldots, n \). We call this type of labeling an \( S_n \) EL-labeling. In Section 5, we prove that the converse result is true: if a finite graded lattice has an \( S_n \) EL-labeling then it is supersolvable.

In Section 3, we describe an action on the maximal chains of an \( S_n \) EL-labeled lattice, suggested to the author by R. Stanley. We show that this action gives a representation of the Hecke algebra of type \( A \) at \( q = 0 \). In [14] and [18], the Frobenius characteristic of the character of some symmetric group actions is shown to be closely related to Ehrenborg’s flag symmetric function. In Section 4, we show that our \( H_n(0) \) action has an analogous property and we follow Simion and Stanley in calling our action a good \( H_n(0) \) action. Note that the material of Section 4 is not necessary for the proof of Section 5. Our second main result appears in Section 6. We show that a certain class of posets, which includes finite graded lattices, have a good \( H_n(0) \) action if and only if they have an \( S_n \) EL-labeling. It follows that a finite graded lattice is supersolvable if and only if it has a good \( H_n(0) \) action.

2. EL-labelings and Supersolvability

Throughout, we let \( s_i \) denote the permutation which transposes \( i \) and \( i+1 \), and composition of permutations will be from right to left. For any positive integer \( n \), write \( [n] \) for the set \( \{1, 2, \ldots, n\} \). Suppose \( P \) is a finite graded poset of rank \( n \), with \( 0 \) and \( \hat{1} \). (For undefined poset terminology, see [17, Ch. 3].) Let \( \text{rk} \) denote the
rank function of $P$, so $\text{rk}(0) = 0$ and $\text{rk}(\hat{1}) = n$. If $x \leq y$ in $P$, let $\text{rk}(x,y)$ denote $\text{rk}(y) - \text{rk}(x)$. If $x \leq y$ in $P$ and $\text{rk}(x,y) = 1$ then we say that $y$ covers $x$. Let $\mathcal{E}(P) = \{(s,t) : t \text{ covers } s \in P\}$, the set of edges of the Hasse diagram of $P$, and let $M(P)$ denote the set of maximal chains of $P$.

A function $\lambda : \mathcal{E}(P) \to \mathbb{Z}$ gives us an edge-labeling of $P$. If $m : s = s_0 < s_1 < \cdots < s_k = t$ is a maximal chain of the interval $[s,t]$, then we write $\lambda(m) = (\lambda(s_0,s_1), \lambda(s_1,s_2), \ldots, \lambda(s_{k-1},s_k))$. The chain $m$ is increasing if $\lambda(s_0,s_1) \leq \lambda(s_1,s_2) \leq \cdots \leq \lambda(s_{k-1},s_k)$. We let $\leq_L$ denote lexicographic order on finite integer sequences: $(a_1,a_2,\ldots,a_k) <_L (b_1,b_2,\ldots,b_k)$ if and only if $a_i < b_i$ in the first coordinate where they differ.

**Definition 2.1.** Let $P$ be a finite graded poset of rank $n$. An edge-labeling $\lambda : \mathcal{E}(P) \to \mathbb{Z}$ is called an EL-labeling if the following two conditions are satisfied:

(i) Every interval $[s,t]$ has exactly one increasing maximal chain $m$.

(ii) Any other maximal chain $m'$ of $[s,t]$ satisfies $\lambda(m') >_L \lambda(m)$.

A poset $P$ with an EL-labeling is said to be edge-wise lexicographically shellable or EL-shellable. This definition of a lexicographically shellable poset first appeared in [2] with the motivating examples being from [15] and [16], which appear as Examples 2.4 and 2.6 below. The ubiquity and usefulness of EL-labelings arises from the fact that if $P$ is EL-shellable, then $P$ is shellable and hence Cohen-Macaulay. Further information on these concepts can be found in [2] and the highly recommended survey article [3]. We will be interested in the following type of EL-labeling:

**Definition 2.2.** An EL-labeling $\lambda$ of $P$ is said to be an $S_n$ EL-labeling if, for every maximal chain $m : 0 = x_0 < x_1 < \cdots < x_n = 1$ of $P$, the map sending $i$ to $\lambda(x_{i-1},x_i)$ is a permutation of $[n]$. In other words, $\lambda(m)$ is a permutation of $[n]$ written in the usual way.

If a poset $P$ has an $S_n$ EL-labeling, or snelling for short, then it is said to be $S_n$ EL-shellable, or snellable for short. Note that the second condition in the definition of an EL-labeling is redundant in this case.

**Example 2.3.** Consider the poset $B_n$, the set of subsets of $[n]$. If $y$ covers $x$ in $B_n$ then $y - x = \{i\}$ for some $i \in [n]$ and we set $\lambda(x,y) = i$. This defines a snelling for $B_n$.

**Example 2.4.** Any finite distributive lattice is snellable. Let $L$ be a finite distributive lattice of rank $n$. By [1, p. 59, Thm. 3], that is equivalent to saying that $L = J(Q)$, the lattice of order ideals of some $n$-element poset $Q$. Let $\omega : Q \to [n]$ be a linear extension of $Q$, i.e., any bijection labeling the vertices of $Q$ that is order-preserving (if $a < b$ in $Q$ then $\omega(a) < \omega(b)$). This labeling of the vertices of $Q$ defines a labeling of the edges of $J(Q)$ as follows. If $y$ covers $x$ in $J(Q)$, then the order ideal corresponding to $y$ is obtained from the order ideal corresponding to $x$ by adding a single element, labeled by $i$, say. Then we set $\lambda(x,y) = i$. This gives us a snelling for $L = J(Q)$. Figure 1 shows a labeled poset and its lattice of order ideals with the appropriate edge-labeling.

**Example 2.5.** The posets shown in Figure 2 are seen to be EL-shellable. However, it can be shown that neither of them is snellable. Notice that the second poset, unlike the first, is a lattice. It appears, together with this EL-labeling, in [12].
Example 2.6. The set of supersolvable lattices is our final example and is also the example most relevant to the remainder of the paper. The following definition first appeared in [16].

Definition 2.7. A finite lattice \( L \) is said to be \textit{supersolvable} if it contains a maximal chain, called an \textit{M-chain} of \( L \), which together with any other chain in \( L \) generates a distributive sublattice.

We can label each such distributive sublattice by the method described in Example 2.4 in such a way that the M-chain receives the increasing label \((1, 2, \ldots, n)\). As shown in [16], this will assign a unique label to each edge of \( L \) and the resulting global labeling of \( L \) is a snelling.

Examples of supersolvable lattices include distributive lattices, the lattice \( \Pi_n \) of partitions of \([n]\), the lattice \( NC_n \) of non-crossing partitions of \([n]\) and the lattice \( L(G) \) of subgroups of a supersolvable group \( G \) (hence the terminology). The supersolvability of \( \Pi_n \) and \( L(G) \) was shown in [16] while [8] contains a proof that \( NC_n \) is supersolvable.

We are now in a position to state our first main result.

Theorem 1. A finite graded lattice of rank \( n \) is supersolvable if and only if it is \( S_n \) EL-shellable.

We will prove Theorem 1 in Section 5.

3. \( H_n(0) \) actions

Let \( P \) be a finite graded poset of rank \( n \) with \( \hat{0} \) and \( \hat{1} \). Suppose \( P \) has a snelling \( \lambda \). Then to any maximal chain \( m : \hat{0} = x_0 < x_1 < \cdots < x_n = \hat{1} \) we can associate
the permutation $\omega_m$ given by

$$\omega_m = (\lambda(x_0, x_1), \lambda(x_1, x_2), \ldots, \lambda(x_{n-1}, x_n)).$$

It is now natural to define the descent set of $m$ to be the descent set of $\omega_m$ and the number of inversions of $m$ to be the number of inversions of $\omega_m$. Suppose $m$ has a descent at $i$. By the snellability of $P$, there exists exactly one chain $m': \hat{0} = x_0 < x_1 < \cdots < x_{i-1} < x'_i < x_{i+1} < \cdots < x_n = \hat{1}$ differing only from $m$ at rank $i$ and having no descent at $i$. This suggests the following definition of functions $U_i : \mathcal{M}(P) \to \mathcal{M}(P)$.

**Definition 3.1.** Let $P$ be a finite graded poset of rank $n$ with $\hat{0}$ and $\hat{1}$ and with an $S_n$ EL-labeling. Let $m$ be a maximal chain of $P$. We define $U_1, U_2, \ldots, U_{n-1} : \mathcal{M}(P) \to \mathcal{M}(P)$ by $U_i(m) = m'$, where $m'$ is the unique maximal chain of $P$ differing only from $m$ at possibly rank $i$ and having no descent at $i$.

Under this definition, we see that the descent set of a maximal chain $m$ of $P$ can also be defined to be the set

$$\{i \in [n-1] : U_i(m) \neq m\}. \quad (1)$$

This definition will be used later for posets $P$ where no snelling is defined.

Observe that $\omega_{m'}$ is the same as $\omega_m$ except that the $i$th and $(i+1)$st elements have been switched. In other words, $\omega_{m'} = \omega_m s_i$. Figure 3 shows an example for the case $n = 4$. Let $m$ be the maximal chain to the left. It has a descent at 2 and therefore $m' = U_2(m) \neq m$. The labels of $m'$ are forced by the fact that $m'$ does not have a descent at 2. We have that $\omega_{m'} = \omega_m s_2$.

We see that the action of $U_1, U_2, \ldots, U_{n-1}$ has the following properties:

1. It is a local action, i.e., $U_i(m)$ agrees with $m$ except possibly at the $i$th rank. Local actions on the maximal chains of a poset have been studied, for example, in [8], [14], [18] and [19].

2. $U_i^2 = U_i$ for $i = 1, 2, \ldots, n-1$. This differs from most of the local actions in the aforementioned papers which were symmetric group actions and so satisfied $U_i^2 = 1$.

3. $U_i U_j = U_j U_i$ if $|i - j| \geq 2$.

4. $U_i U_{i+1} U_i = U_{i+1} U_i U_{i+1}$ for $i = 1, 2, \ldots, n-2$. This requires the snellable property and is left as an exercise for the reader.

Now we compare this to the definition of the 0-Hecke algebra $\mathcal{H}_n(0)$ as discussed in [5], [6] and [9].

**Definition 3.2.** The 0-Hecke algebra $\mathcal{H}_n(0)$ of type $A_{n-1}$ is the $\mathbb{C}$-algebra generated by $T_1, T_2, \ldots, T_{n-1}$ with relations:
(i) $T_i^2 = -T_i$ for $i = 1, 2, \ldots, n - 1$.
(ii) $T_i T_j = T_j T_i$ if $|i - j| \geq 2$.
(iii) $T_i T_{i+1} T_i = T_{i+1} T_i T_{i+1}$ for $i = 1, 2, \ldots, n - 2$.

We can extend the action of $U_1, U_2, \ldots, U_{n - 1}$ on $\mathcal{M}(P)$ to a linear action on $\mathbb{C}M(P)$, the complex vector space with basis $\mathcal{M}(P)$. If we set $T_i = -U_i$ then $U_1, U_2, \ldots, U_{n - 1}$ generate the same $\mathbb{C}$-algebra and so we can now refer to our action on the maximal chains of $P$ as a local $\mathcal{H}_n(0)$ action. In [5, §3.9], Duchamps, Hivert and Thibon describe the special case of this action on distributive lattices. They work in the language of linear extensions of a poset $Q$ which, as we have seen, correspond to snellings of $J(Q)$.

Our action has one further very desirable property which we now discuss.

4. Good $\mathcal{H}_n(0)$ actions

Before stating the fifth property, we must give some background, much of which is taken from the introduction in [14].

Let $P$ be any finite graded poset of rank $n$ with $\hat{0}$ and $\hat{1}$ and let $S \subseteq \{0, 1, \ldots, n - 1\}$. We let $\alpha_P(S)$ denote the number of chains in $P$ whose elements, other than $\hat{0}$ and $\hat{1}$, have rank set equal to $S$. In other words,

$$\alpha_P(S) = \# \{0 < t_1 < \cdots < t_{|S|} < 1 : \{\text{rk}(t_1), \ldots, \text{rk}(t_{|S|})\} = S\}.$$ 

The function $\alpha_P : 2^{[n-1]} \to \mathbb{Z}$ is called the flag $f$-vector of $P$. It contains equivalent information to that of the flag $h$-vector $\beta_P$ whose values are given by

$$\beta_P(S) = \sum_{T \subseteq S} (-1)^{|S-T|} \alpha_P(T).$$

Ehrenborg in [7, Def. 3] suggested looking at the formal power series (in the variables $x = (x_1, x_2, \ldots)$)

$$F_P(x) = \sum_{\hat{0} = t_0 < t_1 < \cdots < t_k = \hat{1}} x_{t_0}^{\text{rk}(t_0, t_1)} x_{t_1}^{\text{rk}(t_1, t_2)} \cdots x_{t_k}^{\text{rk}(t_{k-1}, t_k)},$$

where the sum is over all multichains from $\hat{0}$ to $\hat{1}$ such that $\hat{1}$ occurs exactly once. It is easy to see that the series $F_P(x)$ is homogeneous of degree $n$ and that it is a quasisymmetric function, that is, for every sequence $n_1, n_2, \ldots, n_m$ of exponents, the monomials $x_{j_1}^{n_1} x_{j_2}^{n_2} \cdots x_{j_m}^{n_m}$ and $x_{\hat{j}_1}^{n_1} x_{\hat{j}_2}^{n_2} \cdots x_{\hat{j}_m}^{n_m}$ appear with equal coefficients whenever $i_1 < i_2 < \cdots < i_m$ and $j_1 < j_2 < \cdots < j_m$. The series $F_P(x)$ can also be rewritten as

$$F_P(x) = \sum_{S \subseteq [n-1]} \beta_P(S)L_{S,n}(x),$$

where $L_{S,n}(x)$ denotes Gessel’s fundamental quasisymmetric function

$$L_{S,n}(x) = \sum_{\sum_{\hat{0} = t_0 < t_1 < \cdots < t_k = \hat{1}} x_{t_0} x_{t_1} \cdots x_{t_k},}$$

which constitute a basis for the space of quasisymmetric functions of degree $n$. The case when $F_P$ is a symmetric function is considered in [14] and [18] and we wish, in a sense, to extend this to the case when $F_P$ is a quasisymmetric function. In our brief references to the symmetric function case, we follow the notation of [10]. The usual involution $\omega$ on symmetric functions given by $\omega(s_\lambda) = s_\lambda'$ can be extended to the ring of quasisymmetric functions by the definition $\omega(L_{S,n}) = L_{[n-1]-S,n}$. 

EL-LABELINGS, SUPERSOLVABILITY AND 0-HECKE ALGEBRA ACTIONS ON POSETS
As in [20, Exer. 7.94], where this extended definition appears, we leave it as an exercise to check that it restricts to the ring of symmetric functions to give the usual $\omega$.

We now introduce some representation theory related to our local $H_n(0)$ action. In the symmetric function case, certain classes of posets $P$ have been found to have the property that

$$F_P(x) = \text{ch}(\psi) \quad \text{or} \quad \omega F_P(x) = \text{ch}(\psi)$$

where $\psi$ denotes the character of some local symmetric group action and where ch(\psi) denotes its Frobenius characteristic as defined in [10, §1.7]. In extending these concepts to the $H_n(0)$ case, we follow the definitions in [6] and [9]. The representation theory of $H_n(0)$ is studied by Norton in [11]. There are known to be $2^n - 1$ irreducible representations, all of dimension 1. Since $T_i^2 = -T_i$, the irreducible representations are obtained by sending a set of generators to $-1$ and its complement to 0. We will label these representations by subsets $S$ of $[n - 1]$, and then the irreducible representation $\psi_S$ of $H_n(0)$ is defined by

$$\psi_S(T_i) = \begin{cases} -1 & \text{if } i \in S, \\ 0 & \text{if } i \not\in S. \end{cases}$$

Therefore,

$$\psi_S(U_i) = \begin{cases} 1 & \text{if } i \in S, \\ 0 & \text{if } i \not\in S. \end{cases}$$

Hence the character of $\psi_S$, denoted by $\chi_S$, is given by

$$\chi_S(U_{i_1}U_{i_2}\cdots U_{i_k}) = \begin{cases} 1 & \text{if } i_j \in S \text{ for } j = 1, 2, \ldots, k, \\ 0 & \text{otherwise}. \end{cases}$$

We define its characteristic by

$$\text{ch}(\chi_S) = L_{S,n}(x),$$

and we extend it to the set of all characters of representations of $H_n(0)$ by linearity. We let $\chi_P$ denote the character of the defining representation of our local $H_n(0)$ action on the space $\mathbb{C}M(P)$.

**Proposition 4.1.** Let $P$ be a finite snellable graded poset of rank $n$ with $\hat{0}$ and $\hat{1}$. Then the local $H_n(0)$ action on the maximal chains of $P$ has the property that

$$\omega F_P(x) = \text{ch}(\chi_P). \quad (3)$$

**Proof.** It is sufficient to show that the coefficient of $L_{S,n}$ for any $S \subseteq [n - 1]$ is the same for both sides of (3). By (2),

$$[L_{S,n}] \omega F_P(x) = \beta_P(S^c)$$

where $S^c$ denotes $[n - 1] - S$.

Let $J \subseteq [n - 1]$ and let $\{i_1, i_2, \ldots, i_k\}$ be a multiset on $J$ where each element of $J$ appears at least once. Let $m \in M(P)$. If $U_{i_j}(m) \neq m$ for some $i_j \in [n - 1]$ then $U_{i_j}(m)$ has one less inversion than $m$. It follows that $U_{i_1}U_{i_2}\cdots U_{i_k}(m) = m$ if and
only if the descent set of \( m \) is disjoint from \( J \). Therefore

\[
\chi_P(U_i_1 U_i_2 \cdots U_i_k) = \# \{ m \in M(P) : m \text{ has no descents in } J \}
\]

\[
= \sum_{S \supseteq J} \# \{ m \in M(P) : m \text{ has descent set } S^c \}
\]

\[
= \sum_{S \supseteq J} \beta_P(S^c) \text{ by [3, Thm. 2.2]}
\]

\[
= \sum_{S \subseteq [n-1]} \beta_P(S^c) \chi_S(U_i_1 U_i_2 \cdots U_i_k).
\]

Thus

\[
[L_{S,n}] \text{ch}(\chi_P) = [L_{S,n}] \text{ch} \left( \sum_{S \subseteq [n-1]} \beta_P(S^c) \chi_S \right) = \beta_P(S^c)
\]

as required.

To summarize, we have that if \( P \) is a finite snellable graded poset of rank \( n \), with \( \hat{0} \) and \( \hat{1} \), then \( P \) has a local \( H_n(0) \) action with the property that \( \omega F_P(x) = \text{ch}(\chi_P) \). Following [18], we call such an action a good \( H_n(0) \) action. It is natural to ask what other types of posets have good \( H_n(0) \) actions.

**Example 4.2.** Consider the poset \( P \) shown in Figure 4. As stated in Example 2.5, this poset is not snellable. However, it does have a good \( H_n(0) \) action as described in the following table.

| \( m \) | \( U_1(m) \) | \( U_2(m) \) |
|---|---|---|
| \( m_1 : a < b < d < f \) | \( m_4 \) | \( m_2 \) |
| \( m_2 : a < b < e < f \) | \( m_4 \) | \( m_2 \) |
| \( m_3 : a < c < d < f \) | \( m_3 \) | \( m_4 \) |
| \( m_4 : a < c < e < f \) | \( m_4 \) | \( m_4 \) |

It is easy to check that this gives a local \( H_3(0) \) action. We also have that

\[
\omega F_P(x) = L_{\emptyset,3} + L_{\{1\},3} + L_{\{2\},3} + L_{\{1,2\},3} = \text{ch}(\chi_P).
\]

Therefore, this poset has a good \( H_n(0) \) action.

**Definition 4.3.** A graded poset \( P \) is said to be bowtie-free if it does not contain distinct elements \( a, b, c \) and \( d \) such that \( a \) covers both \( c \) and \( d \), and such that \( b \) covers both \( c \) and \( d \).

In Section 3, we will prove our second main result:

**Theorem 2.** Let $P$ be a finite graded bowtie-free poset of rank $n$ with $\emptyset$ and $\hat{1}$. Then $P$ is $S_n$ EL-shellable if and only if $P$ has a good $\mathcal{H}_n(0)$ action.

In particular, since lattices are bowtie-free, we get the following immediate corollary.

**Corollary 1.** Let $L$ be a finite graded lattice of rank $n$. Then the following are equivalent:

1. $L$ is supersolvable,
2. $L$ is $S_n$ EL-shellable,
3. $L$ has a good $\mathcal{H}_n(0)$ action.

5. **Snellable implies supersolvable**

Our main aim for this Section is to prove Theorem 1.

Let $L$ be a finite graded lattice of rank $n$. We showed in Example 2.6 that if $L$ is supersolvable, then $L$ is snellable. Now we suppose that $L$ is snellable and we wish to prove that $L$ is supersolvable. We let $m_0$ denote the unique maximal chain of $L$ labeled by the identity permutation. Taking $m_0$ to be our candidate $M$-chain, we let $L_m$ denote the sublattice of $L$ generated by $m_0$ and any other chain $c$ of $L$.

It is shown in [1, p.12] and is easy to see that any sublattice of a distributive lattice is distributive. If $c$ is a chain in $L$ that isn’t maximal, then we can extend it to a maximal chain $m$ in at least one way. Then $L_c$ is a sublattice of $L_m$. Therefore, it suffices to show that $L_m$ is distributive for all maximal chains $m$. Our approach will be to define two new posets, $Q_m$ and $J(P_{\omega_m})$, and to show that

$$L_m = Q_m \cong J(P_{\omega_m}).$$

We have seen that if $U_i(m)$ differs from $m$ then $U_i(m)$ has one less inversion than $m$ and that $\omega_{U_i(m)} = \omega_m s_i$. It follows that if $m$ has $r$ inversions then we can find a sequence $U_{i_1}, U_{i_2}, \ldots, U_{i_r}$ such that $U_{i_1} U_{i_2} \cdots U_{i_r}(m) = m_0$. We define $\mathcal{M}_m$, a subset of $\mathcal{M}(L)$, as follows:

$$\mathcal{M}_m = \{ m' \in \mathcal{M}(L) : \exists i_1, i_2, \ldots, i_r \text{ such that } m' = U_{i_1} U_{i_2} \cdots U_{i_r}(m) \}$$

We label the elements of $\mathcal{M}_m$ as they are labeled in $L$. We define $Q_m$ to be the subposet of $L$ with elements

$$\{ u \in L : u \in m' \text{ for some } m' \in \mathcal{M}_m \}$$

and with a partial order inherited from $L$. $Q_m$ can be thought of as the closure of $m$ in $L$ under the operations $U_1, U_2, \ldots, U_{n-1}$. We should note that it is not obvious that every maximal chain of $Q_m$ is in $\mathcal{M}_m$. We wish to obtain a clear picture of the structure of $Q_m$.

We are now ready to start the proof proper of Theorem 1. We break up the argument into a series of small steps.

**Step 1.** Let $m'$ and $m''$ be distinct elements of $\mathcal{M}_m$. Then $\omega_{m'} \neq \omega_{m''}$.

Suppose that $\omega_{m'} = \omega_{m''}$. Let $U_{i_1}, U_{i_2}, \ldots, U_{i_l}$ and $U_{j_1}, U_{j_2}, \ldots, U_{j_l}$ be sequences of minimal length such that $m' = U_{i_1} U_{i_2} \cdots U_{i_l}(m)$ and $m'' = U_{j_1} U_{j_2} \cdots U_{j_l}(m)$.

Then $s_i s_{i_2} \cdots s_{i_l}$ and $s_j s_{j_2} \cdots s_{j_l}$ are both reduced expressions for $\omega_{m'}^{-1} \omega_m$. By Tits’ Word Theorem, $s_i s_{i_2} \cdots s_{i_l}$ can thus be obtained from $s_j s_{j_2} \cdots s_{j_l}$ by a sequence of braid moves (i.e. replace $s_i s_{i+1} s_i$ by $s_{i+1} s_i s_{i+1}$ or vice versa or replace $s_i s_j$ by $s_j s_i$ if $|i - j| \geq 2$.) But by Properties 3 and 4 of the $U_i$ action,
$U_i U_j \cdots U_i(m)$ is invariant under braid moves. We conclude that $m' = m''$, which is a contradiction. Therefore, $\omega_{m'} \neq \omega_{m''}$.

**Step 2.** Let $u \in Q_m$. Then there is a unique chain $m_u \in M_m$ that has increasing labels between $0$ and $u$ and between $u$ and $1$.

Choose any $m' \in M_m$ such that $u \in m'$. Suppose $u$ has rank $i$ in $L$. Apply $U_1, U_2, \ldots, U_{i-1}, U_{i+1}, \ldots, U_{n-1}$ repeatedly to $m'$ to obtain $m_u$. The chain $m_u$ is unique in $M_m$ because it is unique in $L$.

**Step 3.** To each point $u$ of $Q_m$ we can associate the subset $\Lambda_u$ of $[n]$ consisting of the labels on any maximal chain of $[0, u]$ in $L$. Then any two distinct points of $Q_m$ correspond to distinct subsets of $[n]$.

Let $u, v$ be distinct elements of $Q_m$ and suppose $\Lambda_u = \Lambda_v$. Then $\omega_{m_u} = \omega_{m_v}$, contradicting Step 1.

An important tool for the remainder of the proof will be the weak order on permutations of $[n]$.

**Definition 5.1.** Let $v, w$ be permutations of $[n]$. We say that $v \leq_R w$ if there exist $t_1, t_2, \ldots, t_r$ such that $v = ws_{i_1} s_{i_2} \cdots s_{i_r}$ and $ws_{i_1} s_{i_2} \cdots s_{i_k+1} s_{i_k}$ has one less inversion than $ws_{i_1} s_{i_2} \cdots s_{i_k+1}$ for $k = 1, 2, \ldots, r$.

It is known (see, for example, [4, Prop. 2.5]) that $v \leq_R w$ if and only if $\text{INV}(v) \subseteq \text{INV}(w)$, where we define the set of inversions of $v$, $\text{INV}(v)$, by

$$\text{INV}(v) = \{(v(j), v(i)) \in [n] \times [n] : i < j, v(i) > v(j)\}.$$ 

**Step 4.** The labels on the elements of $M_m$ consist of all those permutations $\omega$ satisfying $\omega \leq_R \omega_m$, each occurring exactly once.

Compare the definitions of $M_m$ and $\leq_R$. We see that if $m' \in M_m$ then $\omega_{m'} \leq_R \omega_m$ and if $\omega \leq_R \omega_m$ then there exists $m' \in M_m$ satisfying $\omega_{m'} = \omega$. The fact that $\omega$ occurs only once follows from Step 1.

**Step 5.** Let $u, v \in Q_m$. We know that if $u \leq v$ then $\Lambda_u \subseteq \Lambda_v$. Suppose $\Lambda_u \subseteq \Lambda_v$ for some elements $u, v$ of $Q_m$. Then $u \leq v$.

Construct a permutation $\omega$ as follows:

- Let $\omega(1), \omega(2), \ldots, \omega(|\Lambda_u|)$ be the elements of $\Lambda_u$ taken in increasing order.
- Let $\omega(|\Lambda_u| + 1), \ldots, \omega(|\Lambda_v|)$ be the elements of $\Lambda_v - \Lambda_u$ taken in increasing order.
- Let $\omega(|\Lambda_v| + 1), \ldots, \omega(n)$ be the elements of $[n] - \Lambda_v$ taken in increasing order.

Then, since $u, v \in Q_m$, we have that $\text{INV}(\omega) \subseteq \text{INV}(\omega_m)$ and so $\omega \leq_R \omega_m$. Let $m_{u,v}$ be the element of $M_m$ satisfying $\omega_{m_{u,v}} = \omega$. By Step 3, $u$ and $v$ are both elements of $m_{u,v}$. We conclude that $u \leq v$ in $Q_m$.

We can now exhibit a poset $P_{\omega_m}$ such that $Q_m \cong J(P_{\omega_m})$. Construct $P_{\omega_m}$, a poset on $[n]$ with relation $\leq$ defined by $i \leq j$ if and only if $(i, j) \notin \text{INV}(\omega_m)$. For example, if $\omega_m = 2413$ we get the poset on the left in Figure 1.

**Step 6.** The map $\phi : Q_m \to J(P_{\omega_m})$ defined by $\phi(u) = \Lambda_u$ is an isomorphism.
Suppose $\Lambda_u$ has size $k$.

\[ u \in Q_m \iff \Lambda_u = \{\omega(1),\omega(2),\ldots,\omega(k)\} \text{ for some } \omega \leq \omega_m \]
\[ \iff \Lambda_u = \{\omega(1),\omega(2),\ldots,\omega(k)\} \text{ for some } \omega \text{ satisfying } \]
\[ INV(\omega) \subseteq INV(\omega_m) \]
\[ \iff \Lambda_u \text{ is an order ideal of } P_{\omega_m} \]
\[ \iff \Lambda_u \in J(P_{\omega_m}). \]

Therefore, $\phi$ is a well-defined bijection. If $u$ and $v$ are elements of $Q_m$, by Step 5,

\[ u \leq v \text{ in } Q_m \iff \Lambda_u \subseteq \Lambda_v \iff \Lambda_u \leq \Lambda_v \text{ in } J(P_{\omega_m}) \quad (4) \]

as required.

It follows from this that $Q_m$, up to isomorphism, depends only on $\omega_m$ and not even on the underlying lattice $L$.

**Step 7.** $Q_m$ is a sublattice of $L$.

Let $u, v \in Q_m$ with corresponding subsets $\Lambda_u$ and $\Lambda_v$, respectively. Let $u \vee_L v$ denote the join of $u$ and $v$ in $L$ and let $u \vee_{Q_m} v$ denote the join of $u$ and $v$ in $Q_m$, which we now know is a lattice. In $L$ we have that

\[ u \vee_{Q_m} v \geq u \vee_L v \]

since $Q_m$ is a subposet of $L$. But by (4),

\[ \text{rk}(u \vee_{Q_m} v) = |\Lambda_u \cup \Lambda_v| \leq \text{rk}(u \vee_L v) \]

since there are maximal chains of $[\hat{0}, u \vee_L v]$ going through $u$ and others going through $v$. Thus,

\[ u \vee_{Q_m} v = u \vee_L v. \]

Similarly,

\[ u \wedge_{Q_m} v = u \wedge_L v. \]

We have shown that $Q_m$ is a distributive sublattice of $L$. Furthermore, $L_m$ is a sublattice of $Q_m$ since $L_m$ is a sublattice of $L$ and $Q_m$ contains $m$ and $m_0$. We conclude that $L_m$ is also distributive and hence $L$ is supersolvable.

The astute reader will notice that, while we have shown that $L$ is supersolvable and that $L_m \subseteq Q_m$, we have not fulfilled our promise to show that $L_m = Q_m$. However, this follows from the following lemma.

**Lemma 5.2.** For each element $m'$ of $\mathcal{M}_m$, we have $Q_{m'} = L_{m'}$.

**Proof.** Let $m'$ be an element of $\mathcal{M}_m$ such that $\omega_{m'}$ has $l$ inversions. The proof is by induction on $l$ with the result being trivially true for $l = 0$. Since we know that $L_{m'} \subseteq Q_{m'} \subseteq Q_m$, it suffices to restrict our attention to $Q_m$. We will label the elements of $Q_m$ by their corresponding subsets of $[n]$. By (4), join and meet in $Q_m$ are just set union and set intersection, respectively.

Referring to Figure 5, suppose $m'$ is the vertical chain. Suppose that $|T| = i - 1$ and $a > b$ so that $m'$ has a descent at rank $i$. Now

\[ T + \{b\} = ((T + \{a,b\}) \cap \{1,2,\ldots,a-1\}) \cup T \]
and \( \{1, 2, \ldots, a - 1\} \in \mathfrak{m}_0 \). Therefore, \( T + \{b\} \in L_{m'} \) and so we get that \( L_{U_i(m')} \subseteq L_{m'} \) as sets. Suppose the descents of \( m' \) are at ranks \( i_1, i_2, \ldots, i_k \). Then, as sets,

\[
Q_{m'} = Q_{U_i_1(m')} \cup Q_{U_i_2(m')} \cup \cdots \cup Q_{U_i_k(m')} \cup m' \\
= L_{U_i_1(m')} \cup L_{U_i_2(m')} \cup \cdots \cup L_{U_i_k(m')} \cup m' \quad \text{by induction} \\
\subseteq L_{m'}.
\]

\[ \square \]

**Example 5.3.** A non-crossing partition of \([n]\) is a partition of \([n]\) into blocks with the property that if some block \( B \) contains \( i \) and \( k \) and some block \( B' \) contains \( j \) and \( l \) with \( i < j < k < l \) then \( B = B' \). We order the set of non-crossing partitions by refinement: if \( \mu \) and \( \nu \) are non-crossing partitions of \([n]\) we say that \( \mu \leq \nu \) if every block of \( \mu \) is contained in some block of \( \nu \). The resulting poset \( NC_n \), which is a subposet of the lattice \( \Pi_n \) of partitions of \([n]\), is itself a lattice and has been studied extensively. More information on \( NC_n \) can be found in Simion’s survey article [13] and the references given there.

\( \Pi_{n+1} \) was shown to be supersolvable in [16] and so can be given a snelling \( \lambda \) as in Example 2.6. We can choose the M-chain to be the maximal chain consisting of the bottom element and those partitions of \([n+1]\) whose only non-singleton block is \([i]\) where \( 2 \leq i \leq n+1 \). In the literature, \( \lambda \) is often seen in the following form, which can be shown to be equivalent. If \( \nu \) covers \( \mu \) in \( \Pi_{n+1} \), then \( \nu \) is obtained from \( \mu \) by merging two blocks \( B \) and \( B' \) of \( \mu \). We set

\[
\lambda(\mu, \nu) = \max\{\min B, \min B'\} - 1.
\]

It was observed by A. Björner and P. Edelman in [2] that \( \lambda \) restricts to \( NC_{n+1} \) to give an EL-labeling for \( NC_{n+1} \). In fact, it is readily checked that we get a snelling for \( NC_{n+1} \). Theorem 1 now gives a new proof of the supersolvability of \( NC_{n+1} \).

Figure 6 shows \( NC_4 \) with \( L_m = Q_m \) highlighted for when \( m \) is the maximal chain \( \hat{0} < 24-1-3 < 234-1 \). In this case, \( P_{\omega_m} \) is just 3 incomparable elements and so \( J(P_{\omega_m}) = B_3 \cong Q_m \).

### 6. Lattice Snellings and Good \( \mathcal{H}_n(0) \) Actions

Our main aim for this Section is to prove Theorem 2.

Recall that \( P \) denotes a finite graded bowtie-free poset of rank \( n \) with \( \hat{0} \) and \( \hat{1} \). We suppose that \( P \) has a good \( \mathcal{H}_n(0) \) action and we let \( \chi_P \) denote the character of the defining representation of this action on the space \( \mathbb{C}M(P) \). In other words,
we suppose that there exist functions $U_1, U_2, \ldots, U_{n-1} : \mathcal{M}(P) \rightarrow \mathcal{M}(P)$ satisfying
the following properties:

(1) The action of $U_1, U_2, \ldots, U_{n-1}$ is local.
(2) $U_i^2 = U_i$ for $i = 1, 2, \ldots, n - 1$.
(3) $U_i U_j = U_j U_i$ if $|i - j| \geq 2$.
(4) $U_i U_{i+1} U_i = U_{i+1} U_i U_{i+1}$ for $i = 1, 2, \ldots, n - 2$.
(5) $\omega F_P(x) = \text{ch}(\chi_P)$.

As we have previously suggested, given any maximal chain $m$ of $P$, we define the
descent set of $m$ to be the set

$$\{ i \in [n-1] : U_i(m) \neq m \}.$$ 

We wish to show that $P$ is snellable. The following approach was suggested by R. Stanley. Suppose $P$ has a unique maximal chain $m_0$ with empty descent set. Given
a maximal chain $m$ of $P$, suppose we can find $U_{i_1}, U_{i_2}, \ldots, U_{i_r}$ with $r$ minimal such that

$$U_{i_1} U_{i_2} \cdots U_{i_r}(m) = m_0.$$ (5)

Then to $m$ we associate the permutation $\omega_m = s_{i_1} s_{i_2} \cdots s_{i_r}$ and we label the edges of $m$ by $\omega_m(1), \omega_m(2), \ldots, \omega_m(n)$ from bottom to top. Our proof of the validity of this
approach divides into four main parts. The first task is to show that $m_0$ exists and
is unique. The next is to show that, given $m$, we can always find $U_{i_1}, U_{i_2}, \ldots, U_{i_r}$ satisfying (5). The third task is to show that $\omega_m$ is well-defined. Finally, we must
show that this gives a snelling for $P$.

**Definition 6.1.** Given maximal chains $m$ and $m'$ of $P$, we say that the expression

$$U_{i_1} U_{i_2} \cdots U_{i_r}(m) = m'$$

is restless if $U_{i_r}(m) \neq m$ and if

$$U_{i_j} U_{i_{j+1}} \cdots U_{i_r}(m) \neq U_{i_{j+1}} \cdots U_{i_r}(m) \quad \text{for } j = 1, 2, \ldots, r - 1.$$ 

We say that two sequences $U_{i_1} U_{i_2} \cdots U_{i_r}$ and $U_{j_1} U_{j_2} \cdots U_{j_r}$ are in the same braid class if we can get from one to the other by applying Properties 3 and 4 repeatedly.

It can be readily checked that if $U_{i_1} U_{i_2} \cdots U_{i_r}$ and $U_{j_1} U_{j_2} \cdots U_{j_r}$ are in the same braid class and if $U_{i_1} U_{i_2} \cdots U_{i_r}(m) = m'$ is restless, then $U_{j_1} U_{j_2} \cdots U_{j_r}(m) = m'$ is restless. Here we use the bowtie-free property of $P$. 

**Figure 6.** $NC_4$ with snelling
To every sequence \(i_1, i_2, \ldots, i_r\) such that \(U_{i_1}U_{i_2} \cdots U_{i_r}(m) = m'\), we can associate a counting vector of length \(n - 1\) where the \(j\)th coordinate equals the number of times that \(i_j\) appears in the sequence \(i_1, i_2, \ldots, i_r\). We say that the expression \(U_{i_1}U_{i_2} \cdots U_{i_r}(m) = m'\) is lexicographically minimal (or lex. minimal for short) if no sequence \(U_{j_1}U_{j_2} \cdots U_{j_r}\) in the braid class of \(U_{i_1}U_{i_2} \cdots U_{i_r}\) and satisfying \(U_{j_1}U_{j_2} \cdots U_{j_r}(m) = m'\) has a lexicographically less counting vector.

The following result will help us to complete our first two tasks.

**Lemma 6.2.** Let \(m'\) be any maximal chain of \(P\). Suppose \(U_i(m') \neq m'\). Then there do not exist \(i_1, i_2, \ldots, i_r\) satisfying \(U_{i_1}U_{i_2} \cdots U_{i_r}(m) = m'\).

**Proof.** Suppose there exist \(i_1, i_2, \ldots, i_r\) satisfying \(U_{i_1}U_{i_2} \cdots U_{i_r}(m') = m'\). It suffices to consider the case when \(U_{i_1}U_{i_2} \cdots U_{i_r}(m') = m'\) is restless and lex. minimal. Let \(l \in [n - 1]\) denote the minimum element of the sequence \(i_1, i_2, \ldots, i_r, i\). Since our equation is restless \(U_l\) must occur at least twice in the sequence.

Take any pair of \(U_l\) appearances with no \(U_l\) between them. If we had no \(U_{l+1}\) between them, we could apply Property 3 until we had an appearance of \(U_{l+1}\), contradicting the restless property since \(U_l^2 = U_l\). If there is just one \(U_{l+1}\) between them, we can apply Property 3 to get \(U_lU_{l+1}U_l\) appearing and then apply Property 4 to get \(U_{l+1}U_lU_{l+1}\), contradicting the lex. minimal property. We conclude that, between the two appearances of \(U_l\), there are at least two appearances of \(U_{l+1}\). Choose any two of these appearances of \(U_{l+1}\) that don’t have another \(U_{l+1}\) between them and apply the same argument to show that there must be at least two appearances of \(U_{l+2}\) between them. Repeating this process, we eventually get \(U_lU_l\) appearing, yielding a contradiction. \(\square\)

More generally, we can apply the same argument to prove the following statement:

**Lemma 6.3.** Suppose \(U_{i_1}U_{i_2} \cdots U_{i_r}(m) = m_0\) is restless and lex. minimal. Let \(l\) denote the minimum element of the sequence \(i_1, i_2, \ldots, i_r\). Then \(U_l\) appears exactly once and for \(l < i \leq n - 1\), there must be an appearance of \(U_{i-1}\) between any two appearances of \(U_l\).

The following result is essentially a rephrasing of Property 5 of our good \(H_n(0)\) action into more amenable terms.

**Proposition 6.4.** For all \(S \subseteq [n-1]\), \(\alpha_P(S)\) equals the number of maximal chains of \(P\) with descent set contained in \(S\).

**Proof.** We know that

\[
\chi_P = \sum_{S \subseteq [n-1]} b_{P,S} \chi_S
\]

for some set of coefficients \(\{b_{P,S}\}_{S \subseteq [n-1]}\) and hence

\[
\text{ch}(\chi_P) = \sum_{S \subseteq [n-1]} b_{P,S} L_{S,n}.
\]

By (2) and Property 5, we see that \(b_{P,S} = \beta_P(S^c)\).
Now let \( J = \{i_1, i_2, \ldots, i_k\} \subseteq [n - 1] \). Then
\[
\sum_{S \supseteq J} \beta_p(S^c) = \sum_{S \subseteq [n-1]} \beta_p(S^c) \chi_S(U_{i_1} U_{i_2} \cdots U_{i_k}) \\
= \chi_S(U_{i_1} U_{i_2} \cdots U_{i_k}) \\
= \# \{ m \in \mathcal{M}(P) : m \text{ has no descents in } J \}
\]
by Lemma 6.2. Therefore,
\[
\sum_{S \supseteq J} \beta_p(S^c) = \sum_{S \supseteq J} \# \{ m \in \mathcal{M}(P) : m \text{ has descent set } S^c \}.
\]
Since this holds for all \( J \subseteq [n - 1] \), we get that
\[
\beta_p(S) = \# \{ m \in \mathcal{M}(P) : m \text{ has descent set } S \}
\]
for all \( S \subseteq [n - 1] \). By Inclusion-Exclusion, this is equivalent to
\[
\alpha_p(S) = \# \{ m \in \mathcal{M}(P) : m \text{ has descent set contained in } S \}.
\]

In particular, setting \( S = \emptyset \), we see that \( P \) has exactly one maximal chain, which we denote by \( m_0 \), with no descents. Also, given a maximal chain \( m \) of \( P \), by Lemma 6.2 and the finiteness of \( P \), we can find \( U_{i_1}, U_{i_2}, \ldots, U_{i_r} \) with \( r \) minimal such that \( U_{i_1} U_{i_2} \cdots U_{i_r}(m) = m_0 \). This completes our first two tasks.

Given any maximal chain \( m \) of \( P \), we consider the braid classes of the set of sequences \( U_{i_1}, U_{i_2}, \ldots, U_{i_r} \), such that \( U_{i_1} U_{i_2} \cdots U_{i_r}(m) = m_0 \) is restless. Our next task is to show that there is only one such braid class. Every braid class contains at least one element \( U_{i_1}, U_{i_2}, \ldots, U_{i_r} \), such that \( U_{i_1} U_{i_2} \cdots U_{i_r}(m) = m_0 \) is restless and lex. minimal. For such an element, the minimum, \( l \), of \( i_1, i_2, \ldots, i_r \) is the lowest rank for which \( m \neq m_0 \), by Lemma 6.3. It follows that \( l \) is the same for all the braid classes. It suffices to consider the case when \( l = 1 \).

The following result is central to our proof that there is just one braid class.

**Lemma 6.5.** Suppose that the expressions \( U_{i_1} U_{i_2} \cdots U_{i_r}(m) = m_0 \) and \( U_{j_1} U_{j_2} \cdots U_{j_s}(m) = m_0 \) are both restless. Then there exists an element of the braid class of \( U_{i_1} U_{i_2} \cdots U_{i_r} \) and an element of the braid class of \( U_{j_1} U_{j_2} \cdots U_{j_s} \), both ending on the right with the same \( U_1 \).

**Proof.** Suppose \( U_{i_1} U_{i_2} \cdots U_{i_r} \) and \( U_{j_1} U_{j_2} \cdots U_{j_s} \) are in different braid classes. Without loss of generality, we take them both to be lex. minimal. If \( U_1 \) can be moved to the right-hand end in both by applying Property 3, then there’s nothing to prove. Suppose, by applying Property 3, that \( U_1 \) can be brought to the right end in one sequence but not in the other. Then \( P \) must have the edges shown in Figure 7, where \( m \) and \( m_0 \) are the maximal chains on the left and right, respectively. We see that we get a contradiction with the bowtie-free property unless \( a = b \). In this case, \( U_2 \) appears at least twice in the latter sequence to the right of the unique appearance of \( U_1 \), contradicting Lemma 6.3. We conclude that \( U_1 \) can’t be brought to the right end in either sequence. Now we consider that portion of each sequence to the right of the unique \( U_1 \). By the same logic, the maximal chains we get when we apply these portions to \( m \) must have the same element at rank 2.

Consider the unique \( U_2 \) in each of these portions. By a similar argument, we conclude that either we’ve nothing to prove or else \( U_2 \) can’t be brought to the
right of either sequence by applying Property 3. In the latter case, we consider the portion of each sequence to the right of the unique $U_2$. The maximal chains we get when we apply these portions to $m$ must have the same element at rank 3. Repeating the same argument, we are eventually reduced to the case where $U_i$ is the element at the right end of both sequences, for some $i$.

**Proposition 6.6.** If $U_{i_1}U_{i_2} \cdots U_{i_r}(m) = m_0$ and $U_{j_1}U_{j_2} \cdots U_{j_r}(m) = m_0$ are both restless then $s_{i_1}s_{i_2} \cdots s_{i_r} = s_{j_1}s_{j_2} \cdots s_{j_r}$.

*Proof.* It suffices to prove the result in the case when $r$ is as small as possible. We prove the result by induction on $r$, the result being trivially true when $r = 0$.

For $r > 0$, by the previous lemma, there exists an element $U_{i_1}U_{i_2} \cdots U_{i_{r-1}}U_i$ of the braid class of $U_{i_1}U_{i_2} \cdots U_{i_r}$ and an element $U_{j_1}U_{j_2} \cdots U_{j_{r-1}}U_i$ of the braid class of $U_{j_1}U_{j_2} \cdots U_{j_r}$. Consider $U_i(m)$. By the induction hypothesis,

$$s_{i_1}s_{i_2} \cdots s_{i_{r-1}} = s_{j_1}s_{j_2} \cdots s_{j_{r-1}}.$$

Therefore, since permutations are invariant under braid moves,

$$s_{i_1}s_{i_2} \cdots s_{i_r} = s_{j_1}s_{j_2} \cdots s_{j_{r-1}}s_{i_1} = s_{j_1}s_{j_2} \cdots s_{j_{r-1}}s_{i_1} = s_{j_1}s_{j_2} \cdots s_{j_r}. \qed$$

Finally, we can make the following definition:

**Definition 6.7.** If $U_{i_1}U_{i_2} \cdots U_{i_r}(m) = m_0$ is restless then we define $\omega_m = s_{i_1}s_{i_2} \cdots s_{i_r}$.

For every maximal chain $m$ of $P$, we label the edges of $m$ from bottom to top by $\omega_m(1), \omega_m(2), \ldots, \omega_m(n)$. Our final task is to show that this gives an edge-labeling, and in particular a snelling, for $P$. We divide the proof into a number of small steps.

**Step 1.** If $U_{i_1}U_{i_2} \cdots U_{i_r}(m) = m_0$ is restless then $\omega_m = s_{i_1}s_{i_2} \cdots s_{i_r}$ is a reduced expression. Furthermore, if $\omega_m = s_{j_1}s_{j_2} \cdots s_{j_r}$ is another reduced expression, then $U_{j_1}U_{j_2} \cdots U_{j_r}(m) = m_0$ is restless.

The first assertion follows from the fact that if $\omega_m = s_{i_1}s_{i_2} \cdots s_{i_r}$ is not reduced then we can apply a sequence of braid moves to get $s_is_i$ appearing. This contradicts the restless property. The second assertion follows from Tits’ Word Theorem. \[ ]

**Step 2.** The permutation $\omega_m$ has a descent at $i$ if and only if $U_i(m) \neq m$. In this case, $\omega_{U_i(m)}$ is the same as $\omega_m$ except that the $i$th and $(i+1)$st elements have been switched, removing the descent.
When \( U_i(m) \neq m \)
\[ \Leftrightarrow \quad U_i U_{i_2} \cdots U_{i_r}(m) = m_0 \text{ is restless for some } i_1, i_2, \ldots, i_r \]
\[ \Leftrightarrow \quad s_{i_1} s_{i_2} \cdots s_{i_r} = \omega_m \text{ is a reduced expression for some } i_1, i_2, \ldots, i_r \]
\[ \Leftrightarrow \quad \omega_m s_i \text{ has one less inversion than } \omega_m \]
\[ \Leftrightarrow \quad \omega_m \text{ has a descent at } i. \]

When \( U_i(m) \neq m \) and \( \omega_m = s_{i_1} s_{i_2} \cdots s_{i_r} s_i \) is reduced we see that \( \omega U_i(m) = s_{i_1} s_{i_2} \cdots s_{i_r} s_i \), yielding the second statement. 

**Step 3.** Let \( S \subseteq [n - 1] \). Then every chain in \( P \) with rank set equal to \( S \) has exactly one extension to a maximal chain of \( P \) with descent set contained in \( S \).

Given any chain \( c \) with rank set \( S \), let \( m \) be any extension of \( c \) to a maximal chain in \( P \). Apply \( U_i \) for \( i \notin S \) repeatedly to \( m \). By Step 2, this will eventually yield an extension of \( c \) which is a maximal chain with descent set contained in \( S \). Therefore, every chain with rank set \( S \) has at least one such extension. We get
\[ \alpha_P(S) \leq \# \{ m \in \mathcal{M}(P) : m \text{ has descent set contained in } S \}. \]

However, by Proposition 6.4,
\[ \alpha_P(S) = \# \{ m \in \mathcal{M}(P) : m \text{ has descent set contained in } S \}. \]

Thus \( c \) has exactly one extension to a maximal chain of \( P \) with descent set contained in \( S \).

**Step 4.** For every maximal chain \( m \) of \( P \), labeling the edges of \( m \) from bottom to top by \( \omega_m(1), \omega_m(2), \ldots, \omega_m(n) \) gives an edge-labeling for \( P \).

Let \( x, y \in P \) be such that \( y \) covers \( x \) and let \( m \) and \( m' \) be maximal chains of \( P \) containing both \( x \) and \( y \). Define \( S = [\text{rk}(x), \text{rk}(y)] \) and let \( m_{(x,y)} \) denote the unique extension of \( x < y \) to a maximal chain with descent set contained in \( S \). By applying \( U_i \) for \( i \notin S \) repeatedly to \( m \), we can reach \( m_{(x,y)} \). By Step 2, \( m \) and \( m_{(x,y)} \) give the same label to the edge \((x, y)\). Similarly, \( m' \) and \( m_{(x,y)} \) give the same label to the edge \((x, y)\). Therefore, \( m \) and \( m' \) give the same label to the edge \((x, y)\) so we have an edge labeling for \( P \).

**Step 5.** This edge-labeling is a snelling for \( P \).

Let \( x, y \in P \) be such that \( x < y \). Let
\[ S = [n - 1] - \{ \text{rk}(x) + 1, \text{rk}(x) + 2, \ldots, \text{rk}(y) - 1 \} \]
in Step 3. The fact that the interval \([x, y]\) has exactly one increasing maximal chain follows from Step 3 and the fact that we now have an edge-labeling. Every maximal chain is labeled by a permutation by definition. Therefore, \( P \) is snellable, proving Theorem 2.

**Remark 6.8.** Theorem 2 does indeed contain information not contained in Corollary 1, in that there exist finite graded bowtie-free posets with 0 and 1 that are snellable but are not lattices. For example, take the lattice \( B_4 \) with a snelling as described in Example 2.3. Now delete the edge \((\{3,4\}, \{2,3,4\})\) in the Hasse diagram of \( B_4 \) to form the Hasse diagram of a new poset. We can check that the new poset has the desired properties.
It seems that we have fully answered the question of finite graded posets with \( \hat{0} \) and \( \hat{1} \) in the bowtie-free case. What can we say about such posets that are not bowtie-free? In Example 4.2 we saw a poset with a bowtie that has a good \( \mathcal{H}_n(0) \) action but which is not snellable. On the other hand, Figure 8 shows a finite graded poset with \( \hat{0} \) and \( \hat{1} \) that has a bowtie but which is still snellable.

This suggests the following question.

**Question.** Let \( C \) denote the class of finite graded posets with \( \hat{0}, \hat{1} \) and a good \( \mathcal{H}_n(0) \) action. Is there some “nice” characterization of \( C \), possibly in terms of edge-labelings?

**Acknowledgments**

The results of this paper all came from questions posed by Richard Stanley. I am very grateful to him for this and for many interesting and helpful discussions, especially regarding good \( \mathcal{H}_n(0) \) actions. I am also grateful to Paul Edelman and Patricia Hersh for enthusiastic help with obtaining references and to Noam Elkies for technical help.
