Hierarchical Co–FeS₂/CoS₂ heterostructures as a superior bifunctional electrocatalyst†

Ka Wang,a Weilan Guo,a Shancheng Yan, a,* Haizeng Songa and Yi Shiabc

The traditional method of preparing hydrogen and oxygen as efficient clean energy sources mainly relies on the use of platinum, palladium, and other precious metals. However, the high cost and low abundance limit wide application of such metals. As such, one challenging issue is the development of low-cost and high-efficiency electrocatalysts for such purposes. In this study, we synthesized Co–FeS₂/CoS₂ heterostructures via a hydrothermal method for efficient hydrogen evolution reaction (HER) and oxygen evolution reaction (OER). Benefiting from their unique three-dimensional hierarchical nanostructures, Co-doped FeS₂ and CoS₂ formed heterostructures on Co–FeS₂ petals, which bestowed remarkable electrocatalytic properties upon Co–FeS₂/CoS₂ nanostructures. Co–FeS₂/CoS₂ effectively catalyzed the OER with an overpotential of 278 mV at a current density of 10 mA cm⁻² in 1 M KOH solution, and also is capable of driving a current density –10 mA cm⁻² at an overpotential of –103 mV in 0.5 M H₂SO₄ solution. The overpotential of the OER and HER only decreased by 5 mV and 3 mV after 1000 cycles. Our Co–FeS₂/CoS₂ materials may offer a promising alternative to noble metal-based electrocatalysts for water splitting.

1. Introduction

In response to global energy and environmental problems, researchers have made tremendous efforts to explore and develop high-performance and low-cost electrocatalysts for HER and OER to replace platinum, palladium and other precious metals.¹⁻⁵ Non-noble metal electrocatalysts such as Fe, Co, Ni, Mo, and their sulfides,⁶⁻⁸ phosphides⁹⁻¹² or their alloys¹¹⁻¹⁷ have been investigated widely as electrocatalysts over the past decades. Among them, the low-cost, earth-abundant iron sulfide has attracted much attention as an electrocatalytic material due to its excellent catalytic activity.⁷⁻¹² However, the catalytic performance of iron sulfide is limited by its low surface area and lack of active sites.¹⁹ If the non-noble metals electrocatalysts are grown on carbon material substrates, doping with homologous elements not only reduces the catalytic resistance but also exposes more active sites.²⁰⁻²₂ Furthermore, the formation of epitaxial heterostructures can regulate the energy barrier between the two interfaces to reduce the catalytic kinetic energy.²³⁻²⁵

2. Experimental section

2.1 Chemicals and materials

WOS1009 carbon cloth (CC) was supplied by CeTech Co., Ltd. FeSO₄·7H₂O, was purchased from Shanghai Titan Scientific Co., Ltd. CH₃CSNH₂ was purchased from Aladdin Ltd. Co(NO₃)₂·6H₂O, sulfur powder (S), thiourea (SC(NH₂)₂), Na₂S·9H₂O, C₂H₅OH, H₂SO₄, and KOH were purchased from Nanjing Chemical Reagent Co., Ltd. Ultrapure water was obtained using a Millipore pure water filter (Millipore Q, USA).
2.2 Synthesis of Co–FeS$_2$/CoS$_2$ heterostructures

In this experiment, the carbon cloth (1.8 cm × 2.2 cm) was first ultrasonically clean for 15 minutes using ultrapure water and anhydrous ethanol and then dried. Subsequently, FeSO$_4$·7H$_2$O (1.2 mM), Co(NO$_3$)$_2$·6H$_2$O (0.156 mM), and SC(NH$_2$)$_2$ (1.8 mM) were added to a 30 mL reaction kettle followed by 25 mL of ultrapure water and stirred for 15 minutes to form a transparent homogeneous solution. Sulfur powder (0.72 mM) was then introduced to the above reactor and stirred at a low speed for 15 minutes. After the stirring was stopped, the magnetic stirrer was removed and sulfur powder film was formed on the liquid surface. The clean and dried carbon cloth was inserted vertically into reaction kettle solution and maintained at 180 °C for 8 hours. After the reactor cooled down to room temperature, the solution was removed, and then samples were washed using ultrapure water and absolute ethanol.

2.3 Materials characterization

The crystal phase properties of the samples were analyzed with a Bruker D8 Advance X-ray diffractometer (XRD) using Cu Kα radiation at 40 kV and 40 mA, for 2θ ranging from 20° to 70°, with a scan rate of 0.1° per second. Raman spectra were obtained by Raman spectroscopy (JY T64000) excited at 514.5 nm of a 100 mW Ar$^+$ laser. Scanning electron microscopy (FE-SEM; JSM-7000F) was used to obtain the surface morphology of the sample. The energy dispersive spectrometer (EDS; Inca x-stream 034A0) was used to confirm the elemental composition of the sample. Transmission electron microscope (TEM) and high resolution transmission electron microscope (HRTEM) images were obtained by using a JEOL type JEM2100 instrument at an accelerating voltage of 200 kV. The chemical compositions of samples were determined by using X-ray photoelectron spectroscopy (XPS) analysis (PHI5000 Versaprobe).
2.4 Electrochemical measurements

Electrochemical measurements were performed with a CHI760E electrochemical analyzer (CH Instruments, Chenhua Co., Shanghai, China). A conventional three-electrode cell was used, including the sample as a working electrode, a calomel electrode as a reference electrode, and a graphite rod as a counter electrode. 1 M KOH and 0.5 M H2SO4 solution were used as the electrolyte solution, nitrogen was bubbled into the solution for 30 minutes before testing. In this paper, the positive scan curve is selected as the LSV curve (between 0 and 0.8 V, 2 mV s−1) for OER and the negative scan curve is selected as the LSV curve for HER (between 0.8 and 0.2 V, 2 mV s−1). The Tafel slope is calculated from the logarithmic relationship between overpotential and current density based on the LSV curve. The electrochemical active surface areas (ECSA) were calculated from the double layer charging curves using cyclic voltammograms (CVs) at different scan rates of 2–160 mV s−1 in potential range from 0 to 0.20 V vs. RHE for HER. Electrochemical impedance spectroscopy (EIS) was performed with a frequency range of 105–0.1 Hz. The stability assessment was performed by 1000 cycles of the testing at a scan rate of 100 mV s−1.

3. Results and discussion

In the experiment, we prepared Co–FeS2/CoS2 heterostructures with superior electrocatalytic performance through the selection of sulfur sources, regulation of cobalt content, optimization of loading, addition and optimization of dual sulfur sources (as can be seen in ESI†). Fig. 1a shows the X-ray diffraction (XRD) patterns for Co–FeS2/CoS2 heterostructures and FeS2. The peaks at 28.5°, 33.1°, 37.1°, 40.8°, 47.5° and 56.3° can be indexed to the (111), (200), (210), (220), (311) planes of FeS2 (JCPDS#42-1340).19,26 The peaks at 35.9°, 49.5°, 54.7°, 57.7° and 62.7° correspond to the planes of CoS2 (JCPDS#41-1471).8,27 From the XRD pattern, it can be seen that the Co–FeS2/CoS2 heterostructures exhibit good crystallinity. Fig. 1b shows the Raman spectra of the Co–FeS2/CoS2 heterostructures, FeS2 and CoS2. The Raman spectrum for the Co–FeS2/CoS2 heterostructures shows a broad primary peak centered around 372 cm−1, which is likely the result of contributions from the most intense FeS2 peaks at 378 cm−1 and the primary CoS2 peak at 384 cm−1.28

As shown in Fig. 1c, Co–FeS2/CoS2 exhibits a microflower-like morphology with diameters ranging from 4 to 6 micrometer. Fig. 1d shows the nano-petals structures on the Co–FeS2/CoS2 heterostructures, the nano-petals crosslinked together to form a 3D microflower-like structures,29 which not only increase the specific surface area but also accelerate the outward diffusion rate of the generated gas in the solution for water splitting.30,31 Fig. 1e is a high-resolution SEM image showing the bumps of CoS2 on the nano-petals of the Co–FeS2/CoS2 heterostructures; Co-doped FeS2 decreased the kinetic energy barrier of the catalytic reaction, synergistic catalysis by heterostructures of Co–FeS2/CoS2 further improves electrocatalytic activity.10,32–34 Fig. 1f shows the SEM image and the energy-dispersive X-ray
(EDX) spectrum elemental mapping images of Fe, S and Co, for the Co–FeS2/CoS2 heterostructures, revealing the distribution of the three elements. Fig. 1g is a TEM image of Co–FeS2/CoS2 heterostructures, the inside of the ellipse is a bump of CoS2 which further increased the surface area of the sample and adjusted the kinetic energy. Fig. 1h is a high resolution TEM (HRTEM) image of Co–FeS2/CoS2 heterostructures, the interplanar spacing (210) of FeS2 is 0.24 nm, the interplanar spacings (210) of the CoS2 bump are 0.25 nm, and the inset showed the selected area electron diffraction (SAED) pattern, which shows the monocrystallinity of the sample. All these potentially explain the excellent electrocatalytic performance of the Co–FeS2/CoS2 heterostructures.

Fig. 2a presents the full XPS survey spectrum of the Co–FeS2/CoS2 heterostructures, also confirming the presence of Fe, S and Co elements. Fig. 2b shows the XPS spectrum of Fe (2p); the characteristic peaks of Co–FeS2/CoS2 were detected at 707.8 (Fe 2p3/2) and 720.5 eV (Fe 2p1/2) due to the Fe2+ of the FeS2 structure.7 The peaks at 712.5 and 727.0 eV can be attributed to a small amount of Fe3+ being oxidized to Fe3+8. The XPS spectra of Co–FeS2/CoS2 were measured in the S (2p) region, as shown in Fig. 2c. The binding energies of S (2p) at 162.8 and 164.0 eV belong to S2− of FeS2.9,10 There were some oxidized S species found (168.8 eV) in Co–FeS2/CoS2.11 As shown in Fig. 2d, the Co 2p spectrum can be deconvoluted into four peaks: the Co 2p3/2 and Co 2p1/2 peaks at 782.1 and 797.3 eV can be attributed to Co2+ bound to oxygen,12 while another two peaks at 785.8 and 802.8 eV are ascribed to higher oxidized cobalt species (Co3+).13

We further analyzed the main process of formation of Co–FeS2/CoS2 heterostructures. We speculate the following reaction process: solid sulfur powder attached to the carbon cloth at 180 °C is melted into small droplets. At the sulfur powder droplets and solution interface, due to the severe excess in sulfur powder compared to Fe2+, Co2+, and S2−, Co2+ was incorporated into the reaction of Fe2+, S2−, and sulfur powder droplets (S0). When Co–FeS2 was formed, Co3+ further reacted with sulfur powder droplets (S0)/S2− to form CoS2, thus forming the Co–FeS2/CoS2 heterostructures.

To our knowledge, Co–FeS2/CoS2 heterostructures has not yet been explored for the electrocatalytic splitting of water into hydrogen and oxygen. Unique 3D hierarchical nanostructures not only increase the surface area but also facilitates the release of hydrogen and oxygen from the electrode surface. The superior oxygen evolution performance of the Co–FeS2/CoS2 heterostructures were mainly attributed to the presence of the CoS2 phase and the formation of heterostructures with the Co–FeS2.46 In addition, density functional theory calculation revealed that sulfur was responsible for the active sites for proton adsorption and reduction; the high catalytic activity was stemmed from a large reduction of the kinetic energy barrier of H atom adsorption on FeS2 surface upon Co doping in the iron pyrite structure.18,19 The formation of heterostructures for Co–FeS2 and CoS2 further lowers the kinetic

Fig. 3  (a) LSV curves of Co–FeS2/CoS2, Co–FeS2 (S), Co–FeS2 (SC(NH2)2), and bare CC for OER in 1 M KOH solution; (b) corresponding Tafel plots; (c) LSV curves of Co–FeS2/CoS2 before and after 1000 CV cycles.
energy barrier of the reaction to gain superior electrocatalytic performance.\textsuperscript{23–25}

We used a typical three-electrode system with a sweeping rate of 2 mV s\textsuperscript{−1} to test the OER electrocatalytic activity and stability of the Co–FeS\textsubscript{2}/CoS\textsubscript{2} heterostructures. For comparison study, the electrocatalytic activity of Co–FeS\textsubscript{2} synthesized using sulfur powder or thiourea was also tested. Fig. 3a shows the linear sweep voltammetry (LSV) curves, showing that bare CC almost has no OER activity. Co–FeS\textsubscript{2}/CoS\textsubscript{2} heterostructures shows superior OER activity, with an overpotential of only 278 mV required to drive 10 mA cm\textsuperscript{−2}. This is better than the overpotential of 292 mV for Co–FeS\textsubscript{2} (S) and 333 mV for Co–FeS\textsubscript{2} (SC(NH\textsubscript{2})\textsubscript{2}). Fig. 3b shows that the Tafel slope of Co–FeS\textsubscript{2}/CoS\textsubscript{2} is 73 mV dec\textsuperscript{−1}, which is superior to the measured 98 mV dec\textsuperscript{−1} of Co–FeS\textsubscript{2} (S) and 102 mV dec\textsuperscript{−1} of Co–FeS\textsubscript{2} (SC(NH\textsubscript{2})\textsubscript{2}). As shown in Fig. 3c, the overpotential of Co–FeS\textsubscript{2}/CoS\textsubscript{2} is only 283 mV after 1000 cycles, which signifies Co–FeS\textsubscript{2}/CoS\textsubscript{2} heterostructures have good electrochemical stability in strongly alkaline solutions.

HER activity was analyzed by measuring the LSV curves of Co–FeS\textsubscript{2}/CoS\textsubscript{2} and bare CC in 0.5 M H\textsubscript{2}SO\textsubscript{4} solution. In the polarization curve of Fig. 4a, the blank substrate of CC shows negligible HER activity over the measured voltage range, indicating that the HER performance of the CC has little contribution. The Co–FeS\textsubscript{2}/CoS\textsubscript{2} heterostructures grown on the CC substrate achieved geometric current densities of −10 mA cm\textsuperscript{−2} at much lower overpotential of −103 mV versus the reversible hydrogen electrode (RHE) compared to that of Co–FeS\textsubscript{2} (−161 mV for (S) and −173 mV for SC(NH\textsubscript{2})\textsubscript{2}). As shown in Fig. 4b, Co–FeS\textsubscript{2}/CoS\textsubscript{2} heterostructures have a Tafel slope of 56 mV dec\textsuperscript{−1}, smaller than those for Co–FeS\textsubscript{2} 70 mV dec\textsuperscript{−1} for (S) and 68 mV dec\textsuperscript{−1} for SC(NH\textsubscript{2})\textsubscript{2}. To investigate the origin of the superior activity of Co–FeS\textsubscript{2}/CoS\textsubscript{2} heterostructures, we further estimated the ECSA by calculating its non-faradaic double-layer capacitance using cyclic voltammetry measurement, since ECSA value is linearly proportional to $C_{dl}$. As shown in Fig. S10a–d, cyclic voltammograms were measured in the non-faradaic capacitance current range, the $C_{dl}$ value of hierarchical Co–FeS\textsubscript{2}/CoS\textsubscript{2} is 86 mF cm\textsuperscript{−2} is larger than that of Co–FeS\textsubscript{2}(S) (37 mF cm\textsuperscript{−2}) and Co–FeS\textsubscript{2}(SC(NH\textsubscript{2})\textsubscript{2}) (20 mF cm\textsuperscript{−2}). The result indicates that hierarchical architecture and bump feature can maximize the exposure of accessible active sites, which contributes to excellent electrocatalytic performance of Co–FeS\textsubscript{2}/CoS\textsubscript{2} heterostructures. In addition, as shown in Fig. S10e, the reaction kinetics is verified by EIS, the hierarchical Co–FeS\textsubscript{2}/CoS\textsubscript{2} heterostructures present a smaller semicircle than Co–FeS\textsubscript{2}(S) and Co–FeS\textsubscript{2}(SC(NH\textsubscript{2})\textsubscript{2}), which can be associated with interfacial charge transfer process, a lower value corresponds to a faster electron transfer rate. This result demonstrated further the faster catalytic kinetics of Co–FeS\textsubscript{2}/CoS\textsubscript{2} heterostructures.\textsuperscript{49–51} In addition to catalytic activity, stability is another critical factor to evaluate a good electrocatalyst, we investigated the stability of Co–FeS\textsubscript{2}/CoS\textsubscript{2} heterostructures via 1000 cycles scanning. As shown in Fig. 4c, the Co–FeS\textsubscript{2}/CoS\textsubscript{2} electrode lost only 3 mV of overpotential at −10 mV cm\textsuperscript{−2} after
1000 cycles. Furthermore, we analyzed the characterization results of the Co–FeS$_2$/CoS$_2$ heterostructures before and after the 1000 cycles. As shown in Fig. S11,† it was found that the XRD patterns, XPS spectra, SEM, and TEM images of Co–FeS$_2$/CoS$_2$ heterostructures did not significantly changed. The Co–FeS$_2$/CoS$_2$ heterostructures also has excellent electrochemical stability in 0.5 M H$_2$SO$_4$ solution, which is better than the previously reported non-noble metal-based sulfide electrocatalyst, presented in Table 1.

4. Conclusions

In summary, by optimizing experiment conditions, Co–FeS$_2$/CoS$_2$ heterostructures were successfully prepared by the hydrothermal route with excellent OER and HER electrocatalytic performance. Their unique three-dimensional structure not only increases the surface area but also facilitates the release of hydrogen and oxygen from the electrode surface. Co-doped FeS$_2$ and CoS$_2$ formed heterostructures on the petals of Co–FeS$_2$, which change the energy barrier of the catalytic reaction to gain excellent electrocatalytic performance. This study not only provides a low-cost, stable and earth-abundant iron-based electrocatalyst for efficient water splitting, it will also provide an exciting new method for the rational design and scalable preparation of three-dimensional polynary heterostructures as electrocatalysts.
