Genome-wide profiling to analyze the effects of FXR activation on mouse renal proximal tubular cells

Gui, Ting; Gai, Zhibo

Abstract: To assess the effect of farnesoid X receptor (FXR), a bile acid nuclear receptor, on renal proximal tubular cells, primary cultured mouse kidney proximal tubular cells were treated with GW4064 (a FXR agonist) or DMSO (as controls) overnight. Analysis of gene expression in the proximal tubular cells by whole genome microarrays indicated that FXR activation induced genes involved in fatty acid degradation and oxidation reduction. Among them, genes involved in glutathione metabolism were mostly induced. Here we describe in details the contents and quality controls for the gene expression and related results associated with the data uploaded to Gene Expression Omnibus (accession number GSE70296).

Abstract

To assess the effect of farnesoid X receptor (FXR), a bile acid nuclear receptor, on renal proximal tubular cells, primary cultured mouse kidney proximal tubular cells were treated with GW4064 (a FXR agonist) or DMSO (as controls) overnight. Analysis of gene expression in the proximal tubular cells by whole genome microarrays indicated that FXR activation induced genes involved in fatty acid degradation and oxidation reduction. Among them, genes involved in glutathione metabolism were mostly induced. Here we describe in details the contents and quality controls for the gene expression and related results associated with the data uploaded to Gene Expression Omnibus (accession number GSE70296).

Specifications

| Organism/cell line/tissue | *Mus musculus/kidney/proximal tubular epithelial cells* |
Sex | Male
---|---
Sequencer or array type | Agilent-026655 Mouse GE 4x44k v2
Data format | Raw data: TXT files, normalized data: TXT
Experimental factors | GW4064 vs. DMSO
Experimental features | A unique microarray dataset of FXR effect on renal proximal tubular cells
Consent | All protocols were approved by the Cantonal Veterinary Office in Zurich
Sample source location | Zurich, Switzerland

**Direct link to deposited data [provide URL below]**
Deposited data can be found here: http://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE70296

**Experimental Design, Materials and Methods**

**Primary culture of mouse kidney proximal tubular cells**

Primary proximal tubule cells were isolated from kidneys of C57/BJ mice as described previously (1). Briefly, kidney cortices from mice were dissected, sliced, minced and digested in 0.25% trypsin solution (Life Technologies BRL, Grand Island, NY) in a shaking incubator at 37°C for 1 hour. Trypsin was neutralized with growth medium (DMEM and 10% FBS containing 100 U/ml penicillin and 0.1 mg/ml streptomycin). The suspension was pipetted and was passed through a 100-μm cell strainer (Becton Dickinson Labware, Franklin Lakes, NJ). The samples were centrifuged (600 rpm for 5 minutes) to pellet the tubules, washed with 10 ml of medium, centrifuged, and washed twice more. The final pellet, consisting mostly of renal tubules, was resuspended in culture medium (REBM bullet kit, Clonetics), plated onto culture dishes (Nalge Nunc International, Naperville, IL) and incubated at 37°C in a carbon dioxide incubator with medium changes every 2 days until confluent. Experiments were carried out in serum-free DMEM. To activate FXR, cells were starved for 12 h in 0.2% FBS DMEM, then incubated by the addition of 1μM GW4064 (Sigma-Aldrich, St. Louis, MO USA), or DMSO (as controls) overnight.

**Microarray and gene expression analysis**

RNA was extracted from primary cultured mouse proximal tubule cells using RNeasy Microarray Tissue mini kit (73304, Qiagen, Germany), followed by on column DNase digestion to remove any contaminating genomic DNA. RNA samples from 4 dishes per group were subjected to microarray analysis. Briefly, 100 ng of total RNA was reverse-transcribed into double-stranded cDNA, which was linearly amplified and labelled with Cy3 dye. Following quantification using a Nanodrop spectrophotometer (Witec, Luzern, Switzerland) and quality assessment with Agilent 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA), 1.6 μg of the obtained Cy3-labeled cRNA was hybridized to Mouse GE 4x44K v2 Microarrays (Agilent Technologies, Santa Clara, CA) according to the manufacturer’s protocol. Arrays were scanned with an Agilent G2565CA Microarray Scanner System (Agilent, Santa Clara, CA). Raw intensity data were obtained using Agilent’s Feature Extraction Software version 10.7 for array image analysis and the calculation of spot intensity measurements. All microarray data were submitted to the Gene Expression Omnibus (2)(accession number GSE70296).

**Normalization**
Data analysis was carried out with R/Bioconductor (3). The processed intensities and normalized across samples were loaded by using quantile normalization. All microarray data was submitted to the Gene Expression Omnibus (accession number GSE70296). Differential expression was computed using the limma package (4, 5). More details on analysis methods can be found at http://fgcz-bfabric.uzh.ch/wiki/tiki-index.php?page=app.two_groups. Gene oncology analysis, network analysis and KEGG pathway analysis of the microarray data were completed using the DAVID Bioinformatics Resources (National Institute of Allergy and Infectious Diseases, NIH, USA).

Basic analysis

First, gene expression was compared between GW4064-treated cells versus DMSO-treated cells. By using a ≥1.7-fold change as a cut-off, 550 genes were significantly expressed by FXR activation. Among them, 193 genes were down-regulated and 357 genes were up-regulated (Fig. 1 A). Interestingly, by KEGG pathway analysis, several pathways involved in fatty acid metabolism and oxidation reduction were induced by FXR activation. Pathways belonging to oxidation reduction include glutathione metabolism pathway, drug metabolism pathway and xenobiotics metabolism pathway (Fig. 1 B). Furthermore, by comparison between public available ChIP-seq data (GSE57305, altered mRNA expression profile of GW4064 treated mouse livers compared to vehicle control, http://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE57305 ) with our microarray data (GSE70296, effect of GW4064 on primary cultured mouse kidney proximal tubule cells), we identified that activated FXR could regulate similar pathways in mouse liver in vivo as the pathways in mouse proximal tubular cells (such as glutathione metabolism pathway, drug metabolism pathway, fatty acid metabolism pathway and pyruvate metabolic process pathway), indicating a universal role of FXR in both mouse kidney and liver (Table 1).

Discussion

We described here a unique mRNA profile of GW4064 treated mouse kidney proximal tubular cells. This dataset is composed of genome-wide expression profiling data measured by Agilent platform. We showed that FXR activation by GW4064 induced genes involved in fatty acid metabolism and oxidation reduction. Among them, glutathione metabolism pathway was mostly induced by FXR activation.
