The purpose of this study was to develop a statistical model of anhedonia of depression. The study included 748 healthy controls (350 women, 46.79%, age 21.27 ± 4.72) and 80 patients (32 women, 40%, age 38.36 ± 16.42). The Physical Anhedonia Scale (PhAS), the Social Anhedonia Scale (CSAS), the Positive and Negative Affect Scale (PANAS) and the Beck Depression Inventory (BDI) were administered. Classical Measurement Theory (CTT) and Item Response Theory (IRT) were applied to the collected data. We observed that the general factor of depression status was significantly related with positive emotion ($r = -0.37$, $P < 0.05$), negative emotion ($r = 0.62$, $P < 0.05$) and BDI ($r = 0.48$, $P < 0.01$). A significant difference also was observed between controls and patients. The bifactor model of anhedonia of depression provided a better fit to the data than a unidimensional model. The bifactor model appears to be useful to describe anhedonia in depression.

Keywords: depression; anhedonia; bifactor model analysis

Introduction
Depression is a high-prevalent and debilitating mental disorder associated with low mood, anhedonia, and alterations in behavior and emotional processing (Kaiser, Andrews-Hanna, Wager & Pizzagalli, 2015). The global point prevalence and lifetime prevalence of depressive symptoms are 12.9% and 10.8% respectively (Lim, Tam & Lu, 2018). Anhedonia and depressed mood are core diagnostic criteria for a major depressive episode (MDE) which is a part of MDD according to the Diagnostic and Statistical Manual of Mental Disorders (Fifth Edition, DSM-5) (Marty & Segal, 2015). According to Pelizza’s study, there were one-third depression patients experienced apparently anhedonia (Pelizza & Ferrari, 2009). Anhedonia refers to the reduction of the ability to experience pleasure (Loas, 1996), and there is emotional function damage to anhedonia individuals. The subjective experience of positive emotional stimulation is reduced (positive emotion is weakened), and emotional impairment will further affect social function. In Bethany’s study, they found that lower self-reported position was associated with poor course of MDD (Morris, Bylsma & Rottenberg, 2009). The DSM-5 defines anhedonia as the “diminished interest or pleasure in nearly all activities” which often clinically presented as decreased motivational drive.
and consummatory pleasure (Barbano & Cador, 2006). Previous research had indicated that approximately 70% of individuals with MDD experience clinically significant anhedonic symptoms, making it more challenging for patients to achieve functional recovery (Shankman et al., 2010). What’s more, anhedonia predicts poorer drug treatment response among both adults and adolescents (Uher et al., 2012; Mcmakin et al., 2012).

Different categories of anhedonia can be measured by some outstanding questionnaires such as FCPCS, SHAPS and TEPS (Fawcett, Clark et al., 1983; Snaith et al., 1995; Gard et al., 2006), what’s more, the Chapman physical anhedonia scale (PhAS) and the Chapman social anhedonia scale (SAS) were the most widely used questionnaires (Kosmadakis et al., 1995; Chapman et al., 1976; Horan et al., 2008). In the past, most of the studies independently discussed physical anhedonia (PhA) or social anhedonia (SA) composition, but lacked in-depth analysis of its internal structure. There is no doubt that PhA and SA are two unique components of pleasure impairment (Chapman et al., 1976), but as two major trait dimensions, the Chapman scale essentially measure a kind of pleasure ability. After reviewing the literature, it’s found that there was a high correlation between PhA and SA (Horan et al., 2008), which comprehensively reflected the all-sided emotion management defect. The ability to experience physical pleasure and social pleasure should not be superfluous to each other (Cohen et al., 2011). These two components were usually combined to perform their functions in mental illness. Due to the initial limitations of the scale, the researchers had to select the “true anhedonia” subgroup of subjects who had reached the cut-off point of PhA and SA scores simultaneously (Pelizza & Ferrari, 2009), while PhA and SA scores were generally positively correlated. There was still a debate about whether the two components reflect consistent psychological attributes (Berenbaum & Oltmanns, 1992). The core role of anhedonia may be derived from the impairment of the ability to experience pleasure itself, rather than PhA or SA. These two dimensions should have internal links and related attributes that require in-depth structural analysis. The first purpose of our research was to verify the measurement validity of Chapman anhedonia questionnaire in Chinese clinical and non-clinical population. More importantly, we used bifactor analysis to extract the common components of the two, which was of great value for further understanding the nature of psychopathological trait emotion.

Item Response Theory (IRT) is a theory that uses mathematical modeling to improve the accuracy of psychological measurement. IRT has been widely used in various fields of psychological measurement, including intelligence tests and clinical symptom assessment. Especially, the bifactor model which was newly developed had the performance in improving clinical psychological symptom assessment deserves more attention (Gibbons & Hedeker, 1992). Bifactor model not only improved the accuracy of measurement tools, but also enabled us to have a deeper understanding of the characteristics of psychological symptoms (Thomas, 2011). Bifactor model is a hierarchical model which is assumed that the symptoms of several related psychological disorders are determined by two factors, one is general factor and the other is specific factor. Simms indicated that there was consensus that the large role of general distress or negative affect (NA) plays in the mood and anxiety disorders (Simms et al., 2008). What’s more, they recognized that general factors were insufficient to explain the observed heterogeneity among individuals with emotional or anxiety problems. Instead, most models contain the acknowledgement that specific components may exist to help distinguish between symptom groups (e.g. panic and generalized anxiety) that have universal pain or NA as a component. Finally, these models typically include a hierarchical structure characterized by a general factor at the top (e.g., general distress, NA, internalizing) that
subsumes multiple specific symptom facets at the lower level (Simms, Daniel, Watson & O’Hara, 2008).

For anhedonia, PhA and SA are different clinical manifestations. They should be determined by general anhedonia factors and reflect specific factors of physical anhedonia and social anhedonia to some extent. Elucidating this relationship would be helpful in understanding the nature of anhedonia and its role in psychiatric disorders such as depression. Only through this precise analysis, accurate measurement and effective intervention can be achieved. In order to tease out anhedonia and its clinical manifestations, we used hierarchical bifactor model to extract the general anhedonia components from the PhA and SA. In addition, this research compared the statistical relationship between PhA and SA and clinical indicators (depression, emotion and clinical symptoms), and analyzed the results of the two-dimensional and hierarchical model based on Chapman’s questionnaire. At the same time, we verified the applicability of our model to data by comparing different dimensional models.

**Methods**

**Subjects**

804 university students volunteered to participate in the study, and 56 questionnaires with missing values had been excluded. The final valid control sample was 748 people with mean age 21.27 ± 4.72 (350 women, 46.79%). 83 people with depression from three medical institutions participated in the study, and 3 questionnaires with missing values had been excluded. The final valid patients’ sample was 80 people aged 38.36 ± 16.42 (32 women, 40%). All the subjects were told that their answers are completely confidential. During the study, the patients’ emotional reaction and behavior were monitored by doctors and nurses, and the study was terminated immediately if there was any abnormal situation.

**Material**

A demographic questionnaire collected data including age, gender, years of education, monthly family income, marital status and employment status.

The somatic anhedonia was measured by the PhAS (Physical Anhedonia Scale) which assessed the impairment of an individual’s ability to experience representative measurable physical stimuli, such as food, sex, and the higher scores indicated higher levels of somatic anhedonia. It includes 61 items, and its test-retest reliability is 0.87 and Cronbach’s α is 0.84 (Chapman, Chapman & Raulin, 1976).

The social anhedonia was measured by the SAS (Social Anhedonia Scale) which assessed the individual’s ability to experience non-physical stimuli, such as talking to others or communicating emotional expressions (Eckblad et al., 1982) And the higher scores indicated lower level of pleasure in social interaction. It has 40 items, and its test-retest reliability was 0.80 and Cronbach’s α was 0.82.

PANAS (Positive and Negative Affect Schedule) was used to assess individual’s positive and negative emotion (Watson, Clark & Tellegen, 1988). It has 20 words for positive emotion dimension and 20 words for negative emotion dimension. High positive emotion scores indicated an individual’s energetic, attentive and happy emotional state, while low scores indicate apathy. High scores of negative emotions indicated subjective feelings of confusion and distress, while low scores indicated calmness. In this study, the Cronbach’s α of positive emotion dimension was 0.86 and negative emotion dimension was 0.84.

Depression was measured by Beck Depression Inventory (BDI). BDI has 13 items and each item is assessed with a score of 0–3. In this study, the Cronbach’s α of BDI was 0.88.

**Statistical Analyses**

Classical measurement theory (CTT) and IRT were used to analyze the results of PhAS and SAS, and bifactor model was used to compare model fitting analysis, descriptive analysis was based on the original structure of PhA and SA. Then the changes in the original scale score, the general factor score and the special factor score were compared with
a series of evaluation variables. The specific statistical analyses were based on our previous research (Xie et al., 2012). So, we can get the most accurate results of the severity of the scale. In order to prove the advantages of hierarchical bifactor model, we also analyzed several confirmatory factor analyses to compare the fitting degree of different models, including unidimensional (anhedonia), bidimensional (physical and social anhedonia), and bifactor model (general anhedonia, specific factors such as physical and social anhedonia). Bifactor model can be seen as a combination of single-dimension and two-dimension model, as shown in Figure 1.

Finally, the correlation between anhedonia factor and other psychological variables was tested, including positive and negative emotions, depressive symptoms, and the clinical evaluation of depression degree. All CTT analyses used SPSS23.0, and model fitting comparison was based on confirmatory factor analysis used Lisrel 8.50. Polybif software was used to calculate standardized scores of general factors and two special factors, as well as parameters of each item (Gibbons & Hedeker, 1992).

**Results**

*Classical measurement theory analysis of the Chapman anhedonia scale*

The score of PhAS of controls was significantly lower than in depression patients, and the score of SAS of controls was also significantly lower than in depression patients. See Table 1 for full results.

![Figure 1: Bifactor structure model.](image)

**Table 1: Questionnaire scores as a function of group (mean and standard deviation).**

| Measurement | Group (x ± s) | t     | P    |
|-------------|--------------|-------|------|
| Controls (n = 748) | Depression (n = 80) |
| PhAS       | 17.97 (7.96) | 26.60 (10.49) | 8.91 | <0.001 |
| SAS        | 10.95 (5.77) | 16.65 (8.20)  | 6.06 | <0.001 |
| PANAS      | 30.61 (6.75) | 23.35 (6.92)  | 9.12 | <0.001 |
| PA         | 22.04 (6.17) | 28.50 (7.39)  | 8.72 | <0.001 |
| BDI        | 6.67 (5.67)  | 14.20 (7.60)  | 10.88| <0.001 |

*Note: PA is for positive affect, NA is for negative affect.*
Next, we conducted correlation analysis among subscales, items and total scores. There was a significant positive correlation ($r = 0.52, P < 0.01$) between the two subscales of PhAS and SAS. The scores of items in PhAS and SAS were significantly correlated with the total scores of the other subscale, which were 94.64% and 91.67% respectively. The correlation coefficient ($r_i$) between each item of PhAS and the total SAS score ranged from −0.12 to 0.33 ($P < 0.01$). And the correlation coefficient ($r_j$) between each item of SAS and the total PhAS score ranged from 0.05 to 0.42 ($P < 0.01$). What’s more, the correlation between the two subscales in patients was higher, $r_i$ ranged from −0.14 to 0.45 and $r_j$ ranged from −0.05 to 0.51 ($P < 0.01$). These results implied that the items had multidimensional characteristics, so the multidimensional model should be suitable for the next analysis.

**IRT Bifactor analysis of the Chapman anhedonia questionnaire**

We conducted confirmatory two-factor model analysis on the original scale. As shown in Table 2, the load of 56 PhAS items and 36 SAS items was greater than 0.30. There were

| Item no. | Abbreviated CRPA item | General loadings | Specific loadings | Symptom severitya |
|----------|------------------------|------------------|------------------|------------------|
| 1        | lovemaking usually be intensely pleasurable | -0.308 | 0.202 | -0.472 |
| 2        | enjoy the feel of silk et al. | -0.009 | 0.467 | 0.268 |
| 3        | enjoy feeling the strength in muscles | 0.091 | 0.322 | 0.160 |
| 4        | dancing or the idea of it always dull | 0.498 | 0.113 | 0.460 |
| 5        | piano music dull and unexciting | 0.542 | 0.094 | 0.756 |
| 6        | the test of food has always been important | -0.011 | 0.407 | 0.539 |
| 7        | have little fun from physical activities | 0.581 | 0.022 | 0.747 |
| 8        | seldom enjoy any kind of sexual experience | 0.459 | 0.022 | 0.793 |
| 9        | seldom want to sing along with a good song | 0.401 | 0.069 | 0.638 |
| 10       | always hated the feeling after vigorous activity | 0.463 | 0.054 | 0.517 |
| 11       | seldom matter the color painted on things | 0.339 | 0.056 | 0.680 |
| 12       | the sound of rustling leaves never pleased | 0.555 | 0.152 | 0.766 |
| 13       | prefer King down indoors to sunbathing | 0.520 | 0.037 | 0.490 |
| 14       | little things ever really enjoyed doing | 0.641 | -0.071 | 0.163 |
| 15       | can’t know why people like music so much | 0.617 | 0.040 | 0.764 |
| 16       | flowers aren’t as beautiful as many people claim | 0.647 | 0.114 | 0.591 |
| 17       | always love having back massaged | 0.075 | 0.358 | 0.044 |
| 18       | never want to ride at an amusement park | 0.558 | 0.114 | 0.798 |
| 19       | always enjoy trying new food | 0.297 | 0.515 | 0.732 |
| 20       | warmth of an open fireplace cant sooth and calm | 0.472 | 0.032 | 0.519 |
| 21       | poets always exaggerate the good of nature | 0.382 | -0.078 | -0.069 |
| 22       | the urge to feel a statue | -0.061 | 0.402 | 0.081 |

Note: All samples (N = 828) are used for parameter estimation.  
\(^a\) standardized entry difficulty and critical parameters.
28 items in PhAS (50.00%) and 23 items in SAS (63.89%) with the loading number of general factors greater than that of special factors, indicating that the severity of general factors (general anhedonia) evaluated in these items exceeded that of special anhedonia (namely, physical anhedonia or social anhedonia). The information content of the test (Figure 2) reflected the accuracy of the measurement of general factors by the anhedonia scale, and the information content was greater than 5 in a large range of subjects’ characteristics, which can better reflect the general hedonic impairment of the subjects.

We furthermore calculated the correlations between clinical indicators and anhedonia. After the consideration of general factors, the clinical indicators of the clinical patient group and biPhA and biSA were no longer correlated, as shown in Table 3.

Furthermore, all clinical indicators significantly correlated with the general factor, as shown in Table 4.

**Model fitting analysis**

The fitting indexes of different models were compared to verify the superiority of the bifactor model, as shown in Table 5. The results showed that the bifactor model was better than the single-dimension and two-dimension models. According to the original structure of the scale, the bifactor model integrated the single-dimension model and the two-dimensional model. The results confirmed that the bifactor model provided a more consistent model with the

*Note: PhA is for physical anhedonia, SA is for social anhedonia, PA is for positive affect, NA is for negative affect. biPA and biSA were obtained by bifactor model analysis after considering general factors. * P < 0.05, ** P < 0.01.
observed values than the one-dimensional factor model.

**Discussion**
In this study, the theoretical composition of Chapman’s anhedonia questionnaire was quantitatively analyzed with the bifactor model. Different from the traditional physical anhedonia and social anhedonia approach, this study showed that the anhedonia components in both dimensions had multidimensional characteristics, including general factors and two special factors (biPhA and biSA). Compared with the traditional CTT analysis method, IRT analysis was also sensitive to the overall differences between non-clinical samples and depressed patients, showing significant differences in general factors and two special factors. In addition, IRT was more accurate in reflecting the anhedonia characteristics of depression patients, that is, anhedonia and negative affect of depression patients coexist and interact with each other.

**Table 4:** Descriptive statistics and correlations for the general factor ($\bar{x} \pm s, r$).

| Clinical indicators | General factor |
|---------------------|---------------|
|                     | Controls ($n = 748$) | Depression ($n = 80$) |
| PA                  | $-0.33^{**}$ | $-0.37^*$ |
| NA                  | $0.35^{**}$ | $0.62^*$ |
| BDI                 | $0.47^{**}$ | $0.48^{**}$ |

*Note:* PA is for positive affect, NA is for negative affect. * $P < 0.05$, ** $P < 0.01$.

**Table 5:** Model fitting analysis.

| Model            | CFI | GFI | RMSEA | $\chi^2$ | df  | $\Delta \chi^2$ | $\Delta df$ |
|------------------|-----|-----|-------|---------|-----|-----------------|-------------|
| Unidimensional model | 0.71 | 0.79 | 0.04  | 14693.70 | 4949 | 7083.26**       | 95          |

| Bifactor model          | 0.90 | 0.90 | 0.02  | 7610.44  | 4854 | –               | –           |

*Note:* * $P < 0.05$; ** $P < 0.01$. $\Delta \chi^2$ and $\Delta df$ represent fitting comparison in the one-dimensional model, two-dimensional model and bifactor model.
including expectation, emotion management, memory, motivation, learning and social function. Anhedonia may be comprehensive or specific, including sensory and motor impairments, and may occur outside the field of psychopathology or disease. Bifactor model analysis provides a better understanding of anhedonia in the field of depression and it may indicate the most effective way to treat anhedonia in the future.
