Reduction of hospitalizations for myocardial infarction in Italy in the COVID-19 era

Salvatore De Rosa, Carmen Spaccarotella, Cristina Basso, Maria Pia Calabrò, Antonio Curcio, Pasquale Perrone Filardi, Massimo Mancone, Giuseppe Mercurio, Saverio Muscoli, Savina Nodari, Roberto Pedrinelli, Gianfranco Sinagra, and Ciro Indolfi; on behalf of Società Italiana di Cardiologia and the CCU Academy investigators group

Aims
To evaluate the impact of the COVID-19 pandemic on patient admissions to Italian cardiac care units (CCUs).

Methods and Results
We conducted a multicentre, observational, nationwide survey to collect data on admissions for acute myocardial infarction (AMI) at Italian CCUs throughout a 1 week period during the COVID-19 outbreak, compared with the equivalent week in 2019. We observed a 48.4% reduction in admissions for AMI compared with the equivalent week in 2019 (P < 0.001). The reduction was significant for both ST-segment elevation myocardial infarction (STEMI; 26.5%, 95% confidence interval (CI) 21.7–32.3; P = 0.009) and non-STEMI (NSTEMI; 65.1%, 95% CI 60.3–70.3; P < 0.001). Among STEMs, the reduction was higher for women (41.2%; P = 0.011) than men (17.8%; P = 0.191). A similar reduction in AMI admissions was registered in North Italy (52.1%), Central Italy (59.3%), and South Italy (52.1%). The STEMI case fatality rate during the pandemic was substantially increased compared with 2019 [risk ratio (RR) = 3.3, 95% CI 1.7–6.6; P < 0.001]. A parallel increase in complications was also registered (RR = 1.8, 95% CI 1.1–2.8; P = 0.009).

Conclusion
Admissions for AMI were significantly reduced during the COVID-19 pandemic across Italy, with a parallel increase in fatality and complication rates. This constitutes a serious social issue, demanding attention by the scientific and healthcare communities and public regulatory agencies.

Keywords
COVID-19 • SARS-CoV2 • Acute myocardial infarction • STEMI • Cardiac care units

Introduction
The ongoing pandemic caused by the novel SARS-CoV-2 has already been associated with thousands of deaths worldwide. Italy was one of the first Nations in Europe to be affected. During data collection, the most affected area in Italy was the north of the country, where the healthcare system was overwhelmed with the huge number of patients in need of mechanical ventilation or intensive care. As a way to contain the disease, the government established a stepwise strategy starting from the complete lockdown of initial foci in northern Italy on 20 February 2020 and subsequent adoption of progressively more stringent lockdown measures of the entire nation as of 11 March.
Already during the initial outbreak, many healthcare workers noticed a reduction in patient admissions for acute myocardial infarction (AMI), raising concern among cardiologists across Italy.

Methods

We conducted a multicentre, observational, nationwide survey aimed at evaluating consecutive patients with AMI admitted to Italian intensive cardiac care units (CCUs) throughout a 1 week period during the COVID-19 outbreak in Italy: 12–19 March. The same data were also collected for the equivalent week of 2019. All consecutive AMI patients admitted during the 1 week window were included, independently of their age. AMI was defined according to the Fourth Universal Definition of Acute Myocardial Infarction. Major complications were defined as cardiogenic shock, life-threatening arrhythmias, and cardiac rupture/ventricular septal defect (VSD) or severe functional mitral regurgitation.

Data were analysed for two pre-specified groups of patients: (i) ST-segment elevation myocardial infarction (STEMI); and (ii) non-ST-segment elevation MI (NSTEMI). Additional analyses were planned on segment elevation MI (STEMI); and (ii) non-ST-segment MI (NSTEMI). Data on the number of patients admitted for each of the above-reported diagnoses at CCUs were recorded, along with patients’ age and gender. Collection of data about patients admitted for AMI in both 1 week periods in 2020 and 2019 was mandatory for participation in this survey.

Results

A total of 54 hospitals participated in the study. Of these, 28 (51.9%) were academic hospitals and 26 (48.1%) non-academic hospitals. Among them, 48 (88.9%) were coordinating hubs within the STEMI network, 51 (94.4%) had cardiac catheterization facilities, and 32 (59.3%) had a cardiac surgery unit.

A total of 319 AMIs were registered during the 2020 week, with a 48.4% reduction (95% CI 44.6–52.5) compared with the equivalent week of 2019 (P < 0.001). No difference was registered in mean patient age (65.1% in 2019 vs. 66.5 in 2020; P = 0.495). Within the STEMI...
among STEMI cases was similar in 2020 (29.8%) and 2019 (30.9%). The reduction in admission for NSTEMI was also similar among
women (66.7%; P = 0.018). Both patient- and system-related declared delays were substantially increased during the COVID-19 outbreak. In fact, the time from symptom onset to coronary angiography was increased by 39.2% in 2020 compared with the equivalent week in 2019, while the time from first medical contact to coronary revascularization was increased by 31.5%.

Weekly hospitalizations for NSTEMI went down from 350 in 2019 to 122 in 2020 (65.4% reduction; 95% CI 60.3–70.3; P < 0.001) (Figure 1). No difference was registered in mean patient age (68.9 in 2019 vs. 69.6 in 2020; P = 0.812). The proportion of female patients among NSTEMI cases was similar in 2020 (29.8%) and 2019 (30.9%). The reduction of admission for NSTEMI was also similar among women (66.7%; P < 0.001) and among men (65.4%; P < 0.001). The proportion of NSTEMI patients undergoing percutaneous coronary intervention (PCI) was reduced by 13.3% (P = 0.023) from 2019 (76.7% of NSTEMIs) to 2020 (66.1% of NSTEMIs). The reduction in admissions for NSTEMI was comparable among academic (66.4%) and non-academic hospitals (58.7%) (P = 0.163). The NSTEMI case fatality rate was 3.3% during the pandemic, compared with 1.7% in 2019 (RR = 1.9, 95% CI 0.5–6.7; P = 0.309). Major complications were registered in 10.7% of cases in 2020 and in 5.1% in 2019 (RR = 2.1, 95% CI 1.05–4.1; P = 0.037). Among NSTEMI patients, 12 (9.8%) were SARS-CoV2 positive. No deaths were registered among these.

Since the time course of the COVID-19 outbreak was not synchronous across Italy, we divided the country into three macro-areas to look for possible variations. However, a similar reduction in AMI admissions was registered in North Italy (52.1%), Central Italy (39.3%), and South Italy (52.1%).

A similar reduction in hospitalizations was also registered for HF. In fact, only 82 patients were hospitalized for HF during the 2020 week, compared with 154 during the equivalent week in 2019 (46.8%...
reduction, 95% CI 39.5–55.3; \( P = 0.005 \)). The mean age of HF patients was 72.3 ± 10.1 years in 2019 and 72.9 ± 9.7 in 2020 (\( P = 0.769 \)). The reduction of admissions for HF was similar among men (44.1%; \( P = 0.017 \)) and women (49.2%; \( P = 0.010 \)).

A substantial reduction in hospitalizations was noted for AF. In fact, a total of 41 AF-related hospitalizations were registered during the 2020 week, with a 53.4% reduction (95% CI 43.9–64.9) compared with the equivalent week in 2019 (\( P = 0.017 \)), when 88 patients were hospitalized for the same diagnosis. The mean age of AF patients was 70.0 ± 7.5 years in 2019 and 64.6 ± 12.3 in 2020 (\( P = 0.139 \)).

Finally, a 29.4% reduction (95% CI 0.45–0.89) was registered for DF (\( P = 0.349 \)) while a 63.2% reduction (95% CI 0.14–0.61) was found for PE (\( P = 0.667 \)).

### Discussion

The main finding of the present study is the dramatic reduction in the number of hospitalizations for AMI across Italy during the COVID-19 pandemic. In fact, admissions for AMI were halved during the pandemic compared with the equivalent period of the previous year. The identification of the mechanisms leading to the reduction in admissions for myocardial infarction are beyond the scope of the present work. Nevertheless, it is tempting to speculate that probably a multiplicity of factors, rather than a unique mechanism, contributed to the phenomenon. First, it is possible that the fear of contagion at the hospital has discouraged access to emergency medical services (EMS), particularly after the media diffused the news that the infection was largely spread across hospitalized patients and healthcare personnel due to the lack of personal protection equipment. The similar reduction in AMI admissions across Italy, despite the fact that one might have expected a stronger impact in the North, the most affected area, seems to point in that direction.\(^2\) A second hypothesis is linked to the fact that the emergency medical system was focused on COVID-19 and most healthcare resources were relocated to manage the pandemic. This might have induced an attitude towards deferral of less urgent cases, at both the patient and the healthcare system levels. In line with this hypothesis, the reduction in hospitalizations for STEMI (26.5%) was less striking than with NSTEMI (65.1%). These results are in line with contemporary findings, where an estimated 38% reduction in STEMI activations was reported by US cardiac catheterization laboratories,\(^6\) while a 40% reduction was noticed in Spain.\(^7\) Of note, this seems to also be true for the in-hospital management of AMI patients. In fact, despite the proportion of patients undergoing primary PCIs remaining very high among those admitted for STEMI also during the COVID-19 pandemic, the rate of PCI performed among admitted NSTEMI patients dropped significantly. Despite some CCUs being switched to COVID-19 beds, the reduction of admission for AMI was not linked to the lack of non-COVID-19 beds, as CCU beds in non-COVID-19 areas remained available. Finally, we cannot completely exclude that a true reduction in the incidence of acute cardiovascular disease as the potential result of low physical stress and widespread prevalence of the resting state during the quarantine, especially in the initial phase of the social containment, might have partly contributed to the lower number of admissions for AMI. However, this latter hypothesis is not entirely in line with the delay that we and others observed between symptom onset and hospital admissions for STEMI.\(^8\)

It should also be pointed out that in this COVID-19 outbreak, the time from first medical contact to coronary revascularization was substantially increased in STEMI patients. This is a very important issue since it has been previously demonstrated that primary PCI and reperfusion therapies are necessary, but not sufficient: the efficiency of the care pathway in expediting each step of the process matters tremendously for STEMI patients,\(^10–13\) but is also very relevant to other coronary syndromes.\(^14\) In this regard, the substantial increase in case fatality and complication rates observed during the pandemic points in the same direction.

These data return a frightening picture of about half of AMI patients not reaching out to the hospital at all, which will probably significantly increase mortality for AMI and bring with it a number of patients with post-MI HF, despite the fact that acute coronary syndrome management protocols were promptly implemented.\(^15\) In addition to that, the higher case fatality and major complication rates registered during the hospitalization in this report must sound an alarm bell to healthcare professionals and public regulatory agencies. The higher reduction of admissions for STEMI among women (41.2%) compared with men (25.4%) extends the proportion of the problem, as the already intolerable gender gap in the treatment of AMI is further widened by this social emergency and will most probably result in a further increase in cardiovascular mortality and morbidity among women.\(^10,11\) The lower admission rate for HF (46.8%), PE (63.2%), DF (29.4%), and AF (53.4%) is also worrisome.

### Table 3 Major complications rates

|  | 2019 | 2020 | RR (95% CI) | \( P \)-value |
|---|---|---|---|---|
| AMI | 54 | 618 | 46 (7.4) | 319 | 50 (15.7) | 2.1 (1.4–3.1) | <0.001 |
| STEMI | 54 | 268 | 28 (10.4) | 197 | 37 (18.8) | 1.8 (1.1–2.8) | 0.009 |
| NSTEMI | 54 | 350 | 18 (5.1) | 122 | 13 (10.7) | 2.1 (1.05–4.1) | 0.037 |

Absolute number of patients admitted and the number of major complications during the 2019 (light blue columns) and the 2020 (yellow-shaded columns) index weeks are reported. Risk ratios are reported in the next column, together with 95% confidence intervals (95% CI), followed by the \( P \)-value. Every line reports data on a single disease: AMI = acute myocardial infarction; STEMI = ST-segment elevation myocardial infarction; NSTEMI = non-ST-segment elevation myocardial infarction; Adm = admissions; RR = risk as ratio.
Study limitations
Collecting clinical data during a pandemic is challenging and is exposed to several risks. First, the organization of in-hospital cardiology assistance has certainly been impacted by the situation, as many hospitals underwent functional reorganization to assist COVID-19 patients. For this reason, to avoid under-reporting, we asked participating centres to cross-check their records against records from their catheterization laboratories and COVID-19 wards, as well as with their medical management. Nevertheless, a residual risk might have persisted. Secondly, the management of the pandemic drained most resources, and extensive data collection was not possible, especially during the initial phase. For this reason, we had no choice but to leave out non-essential but potentially relevant variables, such as infant size, clinical risk scores, or the time from symptom onset to admission for NSTEMI cases. For the same reason, the study period was limited to 2 weeks. Despite no relevant differences in weather conditions and no environmental alerts being recorded between those weeks in 2019 and 2020, the use of such a short period for data collection still represents a source for potential bias. Finally, as this is an observational study, we just describe a phenomenon. No demonstration of cause can be drawn from this study.

In conclusion, while healthcare systems along with public opinion, media, and patients were focused on the COVID-19 pandemic, a worrying reduction in admissions for AMI was observed across Italy with a parallel increase in case fatality and complication rates. Timely adoption of countermeasures must be considered to avoid a large and long-standing social impact.
