We present high-statistics results for neutral $B$-meson mixing and heavy-light-meson leptonic decays in the quenched approximation from tadpole-improved clover actions at $\beta = 6.0$ and $\beta = 6.2$. We consider quantities such as $B_{B_{d(s)}}$, $f_{d(s)}$, $f_{B_{d(s)}}$ and the full $\Delta B = 2$ matrix elements as well as the corresponding $SU(3)$-breaking ratios. These quantities are important for determining the CKM matrix element $|V_{td}|$.

1. INTRODUCTION

The study of $B^0_d - \bar{B}^0_d$ oscillations allows a clean extraction of the poorly known CKM matrix element $|V_{td}|$. However, the accuracy of this determination is currently limited by the theoretical uncertainty in the calculation of the matrix element,

$$\Delta m_d = \frac{G_F^2}{8\pi^2} M_W^2 |V_{td}|^2 V_{tb}^* \sum_{x,\mu,\nu} \frac{m_t^2}{M_W^2} C_B(\mu)$$

which is related to the mass difference of the two mass eigenstates of the $B^0_d - \bar{B}^0_d$ system,

$$\Delta m_d = \frac{G_F^2}{8\pi^2} M_W^2 |V_{td}|^2 V_{tb}^* \sum_{x,\mu,\nu} \frac{m_t^2}{M_W^2} C_B(\mu)$$

where $G_F$ is the Fermi constant, $M_W$ the $W$-boson mass, $m_t$ the top-quark mass and $\mu$ the renormalisation scale. $S_0(m_t^2/M_W^2)$ and $C_B(\mu)$ are perturbatively-calculated quantities.

An alternative approach, in which many theoretical uncertainties cancel, is to look at the ratio

$$\frac{\Delta m_s}{\Delta m_d} = \frac{|V_{ts}|^2 M_{B_s} \mathcal{M}_{B_s}}{|V_{td}|^2 M_{B_d} \mathcal{M}_{B_d}} = \frac{|V_{ts}|^2 M_{B_s} \mathcal{M}_{B_s}}{|V_{td}|^2 M_{B_d} \mathcal{M}_{B_d}}$$

where $M_{B_{d(s)}}$ is the meson mass. The matrix elements $\mathcal{M}_{B_{d(s)}}$ can be parameterised as

$$\mathcal{M}_{B_{d(s)}} = \frac{8}{3} f_{B_{d(s)}}^2 M_{B_{d(s)}}^2 B_{B_{d(s)}}$$

where $f_{B_{d(s)}}$ is the decay constant, and $B_{B_{d(s)}}$ the $B$-parameter of $B^0_{d(s)}$ mesons.

In this work, we obtain the ratio $r_{sd}$ from the direct calculation of $\mathcal{M}_{bs}/\mathcal{M}_{bd}$ as well as from the calculations of $f_B/f_{B_d}$ and $B_B/B_{B_d}$.

2. SIMULATION DETAILS

We use the tadpole-improved Sheikholeslami-Wohlert (SW) quark action,

$$S^{SW}_F = S^W_F - i g_0 c_{SW} \frac{\kappa}{2} \sum_{x,\mu,\nu} \bar{q}(x) P_{\mu\nu}(x) \sigma_{\mu\nu} q(x)$$

to perform simulations on a $24^3 \times 48$ lattice at $\beta = 6.2$ and a $16^3 \times 48$ lattice at $\beta = 6.0$. Here $S^W_F$ is the standard Wilson action, $g_0$ the bare gauge coupling, $c_{SW}$ the clover coefficient, $\kappa$ the hopping parameter, and $P_{\mu\nu}$ a lattice definition of the gauge-field strength tensor. Table I gives the simulation parameters. We use KLM normalisation for the quark fields.

3. OPERATOR MATCHING

Matching onto the $\overline{MS}$ scheme is performed at one-loop in perturbation theory using the coupling $\alpha_{\overline{MS}}(\mu)$ defined from the plaquette $\square$. Since
the clover-leaf interaction term is proportional to \( g_0 \), we can use the perturbative results obtained from a tree-level clover action \(^2\) with modifications appropriate for tadpole-improvement and KLM normalisation.

For the matching of four-fermion operators, we use the basis

\[
\begin{align*}
O_1^{lat} &= \gamma_{\mu} \times \gamma_{\mu} + \gamma_{\mu} \gamma_5 \times \gamma_{\mu} \gamma_5, \\
O_2^{lat} &= \gamma_{\mu} \times \gamma_{\mu} - \gamma_{\mu} \gamma_5 \times \gamma_{\mu} \gamma_5, \\
O_3^{lat} &= I \times I + \gamma_5 \times \gamma_5, \\
O_4^{lat} &= I \times I - \gamma_5 \times \gamma_5, \\
O_5^{lat} &= \sigma_{\mu\nu} \times \sigma_{\mu\nu}.
\end{align*}
\]

We set the coupling and matching scales to \( \mu = 1/a \) and, for consistency with the literature, run divergent operators to 5 GeV, using 2-loop continuum RG in the \( \overline{MS} \) scheme with the appropriate number of flavours.

To estimate the systematic error associated with the one-loop matching, we vary the scale \( \mu \) in a range from \( 1/a \) to \( \pi/a \). Decay constants are not affected since they are normalized by \( f_\pi \) and \( B \)-parameters change by about 3% \( (f_\pi \) varies by approximately 3%). Since we are mainly interested in \( SU(3) \)-breaking ratios for which these effects are even smaller, we neglect these small variations in what follows.

### 4. ANALYSIS AND RESULTS

We determine \( \kappa_c \) and \( \kappa_s \) from pseudoscalar meson masses. We set the scale with \( M_\rho \) for spectral quantities and \( f_\pi \) for decay constants. In fact, these two quantities yield remarkably similar scales. (See Table 3.) We then linearly extrapolate and interpolate heavy-light decay constants, \( B \)-parameters and \( \Delta B = 2 \) matrix elements to \( \kappa_c \) and \( \kappa_s \), keeping \( \kappa_c, \kappa_s, aM_\rho \) and \( af_\pi \) in the bootstrap loop. Fig. 1 shows examples of these extrapolations.

**Table 2**

Critical and strange hopping parameters and inverse lattice spacings.

| \( \beta \) | \( \kappa_c \) | \( \kappa_s \) | \( a^{-1}(M_\rho)(\text{GeV}) \) | \( a^{-1}(f_\pi)(\text{GeV}) \) |
|---|---|---|---|---|
| 6.0 | 0.13924(1) | 0.13757(8) | 1.96(5) | 1.92(4) |
| 6.2 | 0.13793(1) | 0.13670(9) | 2.57(8) | 2.58(9) |

**Figure 1.** Light-quark-mass dependence of the heavy-light \( B \)-parameter, \( B_\rho \), and extrapolation (interpolation) to \( \kappa_l = \kappa_c \) (\( \kappa_s \)) at \( \beta = 6.0 \) and 6.2.

For heavy-quark (HQ) extrapolations, we define \( (M_P \) is the heavy-light meson mass)

\[
\Phi_f(M_P) = \frac{af_f}{Z_A} \sqrt{M_P} \left\{ \frac{\alpha_s(M_P)}{\alpha_s(M_B)} \right\}^{\frac{11}{2}}
\]

\[
\Phi_{\Delta F=2}(M_P) = a^4M_P \left\{ \frac{\alpha_s(M_P)}{\alpha_s(M_B)} \right\}^{\frac{11}{4}}
\]

Then for \( X(M_P) = \Phi_f(M_P), \Phi_{\Delta F=2}(M_P), B(M_P) \) and \( SU(3) \)-breaking ratios, HQET predicts

\[
X(M_P) = A_X \left\{ 1 + B_X \left( \frac{M_P}{M_P} \right) + C_X \left( \frac{M_P}{M_P} \right)^2 + ... \right\}
\]

Fig. 2 shows examples of the HQ extrapolations.
For SU(3)-breaking ratios, we find that taking the ratio before or after the HQ extrapolation leads to nearly indistinguishable results. We use the former for our final results since SU(3)-breaking ratios have milder HQ-mass dependences.

Our main results are summarised in Table 3.

We obtain $r_{sd}$ from the direct calculation of $M_{bs}/M_{bd}$ as well as from $f_{B_s}/f_{B_d}$ and $B_{Bs}/B_{B_d}$. Our results for the direct calculation are consistent with those of [3], obtained with propagating Wilson quarks, and, at $\beta = 6.0$, with the static result of [4]. However, as Fig. 3 suggests, it is more difficult to control the chiral and HQ extrapolations of the matrix elements in the direct calculation because these extrapolations are more pronounced.

Because we have results at only two values of the lattice spacing, we cannot extrapolate to the continuum limit. We therefore consider the $\beta = 6.2$ results to be our best, noting that decay constants may still suffer from relatively large discretisation errors (roughly a 2σ effect between 6.0 and 6.2) while SU(3)-breaking ratios and $B$-parameters are consistent within errors at the two $\beta$ values.

Although formally one need not include the $a\partial_\mu P$ correction to the axial current when using a mean-field improved, tree-level clover action, it would be interesting to investigate its effect on our results in view of understanding how non-perturbatively, $O(a)$-improved decay constants may behave. We plan to do so in the future.

For a comparison of our results with other recent results, we refer the reader to [5].

### Table 3

Summary of results. Errors are statistical only.

| $\beta$ | 6.0 | 6.2 |
|---------|-----|-----|
| $f_{D_s}$(MeV) | 239(6) | 221(9) |
| $f_D$(MeV) | 213(6) | 193(10) |
| $f_{B_s}$(MeV) | 221(7) | 190(12) |
| $f_B$(MeV) | 191(10) | 161(16) |
| $B_{B_s}^{\text{nlo}}$(5GeV) | 0.86(2) | 0.85(2) |
| $B_{B}^{\text{nlo}}$(5GeV) | 0.83(4) | 0.85(3) |
| $B_{B_s}/B_{B}$ | 1.03(3) | 0.99(3) |
| $(M_{B_s}/M_{B})^2 B_{B_s}/B_{B}$ | 1.38(7) | 1.37(13) |
| $M_{bs}/M_{bd}$ | 1.52(19) | 1.70(28) |
