SOME ELEMENTARY THEOREMS ABOUT
DIVISIBILITY OF 0-CYCLES ON ABELIAN
VARIETIES DEFINED OVER FINITE FIELDS

HÉLÈNE ESNAULT

ABSTRACT. If $X$ is an abelian variety over a field, and $L \in \text{Pic}(X)$,
we know that the degree of the 0-cycle $L^g$ is divisible by $g!$. As a
0-cycle, it is not, even over a field of cohomological dimension 1,
but we show that over a finite field, there is some hope.

1. INTRODUCTION

Let $X$ be an abelian variety defined over a field $k$, and let $L \in \text{Pic}(X)$. Then the Riemann-Roch theorem implies that the degree of 0-cycle $L^g$
is divisible by $g!$. An important example is when $X$ is the product of
an abelian variety with its dual $A \times A^\vee$, $A$ of dimension $n$, thus $g = 2n$,
and $L$ is the Poincaré bundle, normalized so as to be trivial along the
2 zero sections. In this case, the highest product $L^g$ is just $g!$ times
the origin, as a 0-cycle in $CH_0(A \times A^\vee)$. In this note we investigate
the question of $g!$-divisibility of the 0-cycle $L^g$ in $CH_0(X)$. We show
that already for $g = 2$, there are counter-examples (see Remark 4.1).
This answers negatively a question by B. Kahn: there are no divided
powers in the Chow groups of abelian varieties, not even in their étale
motivic cohomology. Indeed, his question was the motivation to study
divisibility of the 0-cycle $L^g$. Our method consists in relating this
divisibility for $g = 2$ to the existence of theta characteristics on smooth
projective curves over the given field. Over finite fields, Serre’s theorem
asserts that there are always theta characteristics. We derive from this
that if $g = 2n$ and the field is finite, one always has 2-divisibility (see
Theorem 2.1, Remark 4.3). Thus, the 2-divisibility is an arithmetic
statement (see Remark 4.2). In order to find a non-trivial class of
invertible sheaves $L$ for which one has $g!$-divisibility, one needs more
arithmetic. In Theorem 3.1 we show that a principal polarization $L$
of geometric origin has the strong property that $L^g$ is $g!$-divisible as a
0-cycle. Aside of Serre’s theorem mentioned above, the proof relies on
Hélène Esnault

(a translation of) Mattuck’s results on geometric polarization ([2]), on abelian class field theory by K. Kato-S. Saito ([3]) and on S. Bloch’s theorem on 0-cycles on abelian varieties ([2]). Perhaps it gives some hope that \( g! \)-divisibility is true in general over a finite field.

Acknowledgement: The note is an answer to a question by B. Kahn. S. Bloch explained to us long ago the use of abelian class field theory to compute 0-cycles over finite field. This note relies on this idea. J.-P. Serre explained to us his theta theorem. We thank them all, and also E. Howe, A. Polishchuk, and E. Viehweg for answering our questions. In particular, Remark 4.2 comes from a discussion with E. Viehweg.

2. \( 2! \)-divisibility

**Theorem 2.1.** Let \( X \) be an abelian variety of dimension \( g = 2n \) defined over a finite field. Let \( L \in \text{Pic}(X) \) be a line bundle. Then the 0-cycle \( L^g \) is divisible by 2 in the Chow group of 0-cycles of \( X \).

**Proof.** If \( A \) is a sufficiently ample line bundle, then \( L \otimes A = B \) is very ample as well. One has \( L^g \equiv A^g + B^g \mod 2\text{CH}_0(X) \), thus one may assume that \( L \) is as ample as necessary. For \( L \) sufficiently ample, then there is a finite field extension \( k' \supset k \) of odd degree, such that the intersection \( C \subset X \times_k k' \) of \( (g - 1) \) linear sections of \( L \times_k k' \) in general position is smooth. One has \( \omega_C = (L \times_k k')^{\otimes (g-1)} \mid_C \equiv (L \otimes_k k') \mid_C \mod 2\text{Pic}(C) \), thus via the Gysin homomorphism \( \text{Pic}(C) \to \text{CH}_0(X \times_k k') \), one has \( (L \times_k k')^g \equiv \iota_*(\omega_C) \mod 2\text{CH}_0(X \times_k k') \). On the other hand, Serre’s theorem [1], p.61, Remark 2, asserts that a smooth curve over a finite field admits a theta characteristic, that is that \( \omega_C \) is \( 2 \)-divisible in \( \text{Pic}(C) \). This shows that \( (L \times_k k')^g \in 2\text{CH}_0(X \times_k k') \), thus by projection formula, since \( k' \supset k \) is odd, that \( L^g \in 2\text{CH}_0(X) \) as well. \( \square \)

3. \( g! \)-divisibility

Let \( C \) be a smooth projective curve of genus \( g \) defined over a finite field \( k = \mathbb{F}_q \). Then \( C \) has carries a 0-cycle \( p \) of degree 1. Let \( J \) be the Jacobian of \( C \). The rest of this section is trivial if \( g \leq 1 \) thus we assume that \( g \geq 2 \). We consider the cycle map

\[ \psi_p : C \to J, \quad y \mapsto \mathcal{O}_C(y - \deg(y) \cdot p). \]

The cycle map induces a birational morphism which we still denote by \( \psi_p \)

\[ \psi_p : \text{Sym}^g(C) \to J, (x_1, \ldots, x_g) \mapsto \otimes_{i=1}^g \psi_p(x_i). \]
In particular, writing \( p = \sum_i m_i p_i = q_1 - q_2 \), with \( q_i \) effective, one has \( \deg(q_1) - \deg(q_2) = \sum_i m_i \deg(p_i) = 1 \). We denote by \( \pi : C^g \to \text{Sym}^g(C) \) the quotient map. It defines the divisor
\[
D_p = \sum_i m_i (\psi_p \circ \pi)_* (C^g - 1 \times p_i), \quad L_p = \mathcal{O}_J(D_p) \in \text{Pic}(J).
\]

We know that \( L_p \) is a principal polarization, thus the 0-cycle \( L_p^g \) has degree \( g! \). The purpose of this section is to show

**Theorem 3.1.** The 0-cycle \( L_p^g \) in the Chow group \( CH_0(J) \) of 0-cycles of \( J \) is divisible by \( g! \) in \( CH_0(J) \), that is there is a 0-cycle \( \xi \in CH_0(J) \) of degree 1 with \( L_p^g = g! \cdot \xi \in CH_0(J) \).

**Proof.** Since the 0-cycle \( p \) of degree 1 won’t change during the proof, we simplify the notation and set \( \psi = \psi_p, D = D_p, L = L_p \). We consider the Poincaré bundle
\[
P = p_1^* L \otimes p_2^* L \otimes \mu^* L^{-1} \in \text{Pic}(J \times J)
\]
where \( \mu : J \times J \to J, \mu(x, y) = x + y \). Via the cycle map
\[
\iota_* : \text{Alb}(C) = \text{Pic}(C)^0 = \text{Pic}(J)^0 \xrightarrow{\psi_*} CH_0(J)^{\deg=0} \xrightarrow{h} J(k),
\]
where \( h \) is the Albanese mapping of \( J \), one defines
\[
\iota_* \omega_C(-2(g - 1)p) = y \in J(k).
\]

We now adapt [4], section 6 to the situation where \( p \) is not necessarily a \( k \)-rational point of \( C \), but only a 0-cycle of degree 1. One defines the involution
\[
\delta : J \to J
\]
\[
x \mapsto -x + y = \tau_y \circ (-1)^* (x) = (-1)^* \circ \tau_{-y}
\]
where \( \tau_y \) is the translation by \( y \) while \( (-1)^* \) is the multiplication by \( -1 \). We set
\[
\ell = \psi^* L
\]
\[
\mathcal{P} = (\psi \times 1)^* P = p_1^* \ell \otimes p_2^* L \otimes (\psi \times 1)^* \mu^* L^{-1}.
\]
As in [5], p. 249, for \( d > 2g - 2 \), the Riemann-Roch theorem asserts that
\[
E_d := p_2^* (\mathcal{P} \otimes p_1^* \mathcal{O}_C(dp)) = Rp_2^* (\mathcal{P} \otimes p_1^* \mathcal{O}_C(dp))
\]
is a vector bundle. One has
\[
\otimes_i \mathcal{P}_{|p_i \times J}^{\otimes m_i} = \mathcal{P}_{|C \times \{0\}} = \mathcal{O}_J.
\]
This implies that for any natural number \( f > 0 \) one has
\[
(3.1) \quad \mathcal{P}_{f_1 \times J} \otimes \mathcal{P}_{f_2 \times J}^{-1} = \mathcal{P}_{|C \times \{0\}} = \mathcal{O}_J.
\]
For two natural numbers $e > f > 0$, one has the diagram
\[
\begin{array}{c}
\mathcal{P} \otimes p_1^* \mathcal{O}_C((e - f)q_1 - eq_2) \xrightarrow{f_{q_1}} \mathcal{P} \otimes p_1^* \mathcal{O}_C(ep) \\
\downarrow f_{q_2} \\
\mathcal{P} \otimes p_1^* \mathcal{O}_C((e - f)p)
\end{array}
\]
where the horizontal map is induced by $\mathcal{O}_C \to \mathcal{O}_C(fq_1)$ and the vertical one by $\mathcal{O}_C \to \mathcal{O}_C(fq_2)$. Thus one has the relation in $K_0(J)$
\[
Rp_{2*}(\mathcal{P} \otimes p_1^* \mathcal{O}_C(ep)) - Rp_{2*}(\mathcal{P} \otimes p_1^* \mathcal{O}_C((e - f)p)) =
\]
\[
p_{2*}(\mathcal{P} \otimes p_1^* \mathcal{O}_C((e - f)p)|_{f_{q_2} \times J})^{-1} \otimes p_{2*}(\mathcal{P} \otimes p_1^* \mathcal{O}_C(ep)|_{f_{q_1} \times J}) \cong 0.
\]
For $d > 2g - 2$, we then have in the Grothendieck group $K_0(J)$
\[
(3.2) \quad p_{2*}(\mathcal{P} \otimes p_1^* \mathcal{O}_C(dp)) + R^1p_{2*}(\mathcal{P} \otimes \mathcal{O}_C((2g - 2 - d)p) = 0.
\]
On the other hand, one has
\[
\delta^*E_d = p_{2*}(\mathcal{P}^{-1} \otimes p_1^* \omega_C((d - 2g + 2)p))
\]
and Serre duality implies
\[
(3.3) \quad \delta^*(E_d^\vee) = R^1p_{2*}(\mathcal{P} \otimes p_1^* (\mathcal{O}((2g - 2 - d)p)))
\]
(see [5], p. 249). The involution $\delta$ acts on $J$, thus on the Chow groups of $J$. Thus (3.2) and (3.3) imply
\[
\delta^*c_1(E_d) = c_1(E_d) =: M, \ M^2 = \delta^*M^2 = c_2(E_d) + \delta^*c_2(E_d).
\]
Thus we have
\[
(3.4) \quad M^g = M^2 \cdot M^{g-2} =
\]
\[
M^{g-2}c_2(E_d) + \delta^*M^{g-2} \cdot \delta^*c_2(E_d) = Z + \delta^*Z
\]
for
\[
Z := c_2(E_d) \cdot M^{g-2} \in CH_0(J), \ \deg Z = n, 2n = \deg M^g.
\]
Let us set
\[
Z' = Z - n\{0\} \in CH_0(J)_{\deg = 0}.
\]
By abelian class field theory for 0-cycles on varieties defined over finite fields, [3], Corollary p. 274, the Albanese mapping $h$ is an isomorphism. This allows to identify explicitly $\delta^*$ on $CH_0(J)$. Indeed, if $W \in CH_0(J)$ has degree $n$, and if $z \in J(k)$, then
\[
(3.5) \quad h(\tau_z^*(W) - n\{0\}) = \tau_z^*h(W - n\{0\}) + h(\tau_z^*n\{0\} - n\{0\}) =
\]
\[
\tau_z^*h(W - n\{0\}) + nz.
\]
On the other hand, S. Bloch’s theorem [2], Theorem 3.1 asserts that the second Pontryagin product dies in $CH_0(J \times_k \bar{k})$, where $\bar{k}$ is the algebraic closure of $k$, thus by class field theory again [3], p. 274 Proposition 9, it dies in $CH_0(X)$. Thus

$$\tau_*^*a = a \text{ for all } a \in CH_0(X)^{deg=0}.$$ (3.6)

Thus (3.5) and (3.6) imply

$$h(\tau_*^*(W) - n\{0\}) = h(W - n\{0\}) + nz.$$ (3.7)

On the other hand

$$h((-1)^*W - n\{0\}) = -h(W - n\{0\}).$$ (3.8)

Thus, (3.4), (3.7) and (3.8) imply

$$h(M^g - 2n\{0\}) = -ny.$$ (3.9)

We now apply again Serre’s theorem [1], p. 61, Remark 2, which asserts that over a finite field, a smooth projective curve has a theta divisor. Thus $\omega_C(-(2g-2)p) \in 2\text{Pic}^0(C)$ and a fortiori via the Gysin homomorphism $\psi$, one has

$$y = 2\xi_0 \in CH_0(J)^{deg=0}, \text{ for some } \xi_0 \in CH_0(J)^{deg=0}.$$ (3.10)

Thus (3.9), (3.10), and [3], loc. cit. imply

$$M^g = 2n(\{0\} - \xi_0).$$ (3.11)

It remains to compare $M^\vee$ and $L$. As a divisor, one has $M^\vee \otimes_k \bar{k} = \{L \in \text{Pic}^0(J)(\bar{k}), \Gamma(C \times_k \bar{k}, L((g-1)p)) \neq 0\}$. Thus $M^\vee \otimes_k \bar{k} = \mathcal{O}_{J \times_k \bar{k}}(D)$, as we know, both underlying divisors are physically the same and they are both reduced. Thus $M^\vee = \mathcal{O}_J(D) \otimes \mathcal{L}$ for some $\mathcal{L} \in \text{Pic}^0(J)$ which is torsion. On the other hand, the map $J \to \text{Pic}^0(J), a \mapsto \tau_a^*\mathcal{O}_J(D) \otimes \mathcal{O}_J(D)^{-1}$ is an isomorphism over $\bar{k}$, thus is an isomorphism over $k$. This implies that $M^\vee = \tau_a^*\mathcal{O}_J(D)$ for some $a \in J$. Thus (3.11) implies

$$L^g = 2n\tau_a^*(\xi_0 - \{0\}), \quad 2n = g!.$$ (3.12)

This finishes the proof.

4. Remarks

**Remark 4.1.** B. Kahn asked whether étale motivic cohomology of abelian varieties has divided powers. Theorem 2.1, read backwards, yields a negative answer. Let $k$ be a field, and let $C$ be a genus 2 curve defined over this field with the two properties that it carries a 0-cycle $p$ of degree 1 and it does not have a theta characteristic. Let $J$ be the
Jacobian of $C$ and $\psi_p =: \psi : C \to J$ be the cycle map assigned to the choice of $p$. The composite map $\iota_\ast : \text{Alb}(C) = \text{Pic}(C)^0 = \text{Pic}(J)^0 \xrightarrow{\psi} CH_0(J)^{\deg=0} \xrightarrow{\Delta_p} J(k)$ being an isomorphism, one has $\iota_\ast \omega_C(2(g-1)p) \in J(k)$ is not 2-divisible. Thus a fortiori, the class of the Gysin image of $\omega_C$ won’t be 2-divisible in any cohomology which has the property that it maps to étale cohomology and the kernel maps to the Albanese. For example, étale motivic cohomology.

It remains to give a concrete curve. One could take for $k$ the function field of the fine moduli space of pointed genus 2 curves with some level over a given algebraically closed field $F$. This has transcendence degree 3 over $F$ and is of course very large. Here is an example due to J.-P. Serre over the field $k = \mathbb{C}(t)$ of cohomological dimension 1:

$C$ is defined by its hyperelliptic equation $y^2 = x^6 - x - t$. It has 2 rational points at $\infty$. The Galois group of $x^6 - x - t$ is the symmetric group in 6 letters, which acts with 2 orbits on the space of theta characteristics over $\overline{k}$, one with 6 elements and one with 10.

Remark 4.2. This remark arose in discussions with E. Viehweg in view of Theorem 2.1. If $X$ is a product of curves $X = C_1 \times \ldots \times C_g$ over a field $k$, then the Pic functor is quadratic after Mumford, which means that a line bundle $L$ on $X$ is a sum of line bundles $L_{ij}$ coming via pull-back from only 2 factors $(ij), i \neq j$. Thus the expansion of $L^g$ will have two kinds of summands. Those of the type $L_{i_1j_1} \cdots L_{i_gj_g}$ with all pairs $(i_c, j_c)$ being different. The coefficient of such a summand is $g!$ thus this term is $g!$ divisible. Then those of the type $L_{i_1j_1}^2 \cdots L_{i_a,j_a}^2 \cdots L_{i_{a+1},j_{a+1}}^2 \cdots L_{i_{a+b},j_{a+b}}$ with all pairs $(i_c, j_c)$ being different and $2a+b = g$. The coefficient of such a summand is $\frac{g!}{2^a}$. Thus $g!$ divisibility of any $L^g$ on a product of $g$ curves splits up into two kinds of divisibility. Over any field $k$, geometry always forces $\frac{g!}{2^a}$ divisibility for $a = \lfloor \frac{g}{2} \rfloor$, where $[c]$ means the integral part of a real number $c$. On the other hand, let $k$ be a field which has the property that any curve has a theta characteristic, e.g. a finite field ([1], p.61, Remark 2). Then the argument of Theorem 2.1 implies that if $L \in \text{Pic}(C_1 \times C_2)$, then $L^2$ is 2-divisible. Indeed, one reduces as in the proof of Theorem 2.1 to the case where $L = \mathcal{O}(\Gamma)$ for a smooth curve $\Gamma \subset C_1 \times C_2$ and by the adjunction formula one has $L^2 = i_\Gamma^* \omega_{\Gamma} - p_1^* \omega_{C_1} \cdot \Gamma - p_2^* \omega_{C_2} \cdot \Gamma$ where $p_i : C_1 \times C_2 \to C_i$ and $i_\Gamma : \Gamma \to C_1 \times C_2$ is the closed embedding. Thus over such a field, $L^g$ is always $g!$-divisible in $CH_0(C_1 \times \ldots \times C_g)$.

Remark 4.3. The conclusion of Theorem 2.1 is of course true over any field $k$ over which any smooth projective curve has a theta characteristic.
