Should isolated aberrant right subclavian artery be ignored in the antenatal period? A management dilemma

Abstract

Objective: To investigate the frequency and types of chromosomal abnormalities in fetuses with the aberrant right subclavian artery (ARSA) and to evaluate its association with other ultrasonographic findings.

Materials and Methods: In all, 11,666 fetal anatomic surveys were performed between March 2014 and March 2020. The cases diagnosed as ARSA were examined. Accompanying ultrasound findings and chromosomal abnormalities were collected.

Results: ARSA was detected in 140 fetuses (1.2%). The ARSA appeared isolated in 47.1% (66/140) of cases and the remaining 52.9% (74/140) of cases were associated with cardiac or extracardiac malformations and soft markers. Chromosomal abnormalities were detected in 17.8% (25/140) of all cases. Trisomy 21 was the most common chromosomal anomaly with a prevalence of 11.4% (16/140). The corresponding rate was 3% (2/66) and 18.9% (14/74) for isolated and non-isolated ARSA, respectively. DiGeorge syndrome was detected in 3% (n=2) and Turner syndrome was in 3% (n=2) of the isolated group. ARSA was not an isolated finding in any of the 4 fetuses with trisomy 18.

Conclusion: Isolated ARSA may be the only antenatal predictor of trisomy 21 or other chromosomal anomalies, including DiGeorge or Turner syndrome. Hence, visualization of the right subclavian artery should be a part of the fetal anatomic survey and genetic analysis should be recommended even in the absence of associated findings.

Keywords: Aberrant right subclavian artery, DiGeorge syndrome, Down syndrome, Turner syndrome, prenatal diagnosis

Öz

Amaç: Aberran sağ subklavyen arteri (ASSA) olan fetüslerde kromozomal anomalilerin sıklığı ve tiplerini belirlemek ve diğer sonografik bulgularla iliskisini değerlendirilmektedir.

Gereç ve Yöntemler: Mart 2014 ile Mart 2020 tarihleri arasında toplam 11,666 fetal anatomik inceleme yapıldı. ASSA tanısı konulan olgular incelendi. Eşlik eden ultrason bulguları ve kromozom anormallikleri toplandı.

Bulgular: Yüz kırk fetüste (%1,2) ASSA tespit edildi. ASSA, olguların %47,1’inde (66/140) izole olarak görüldü ve olguların geri kalan %52,9’u (74/140) kardiak anomaliler, ekstrakardiak malformasyonlar veya minor belirteçler ile ilişkili bulundu. Tüm olguların %17,8’inde (25/140) kromozom anomalileri tespit edildi. Trizomi 21, %11,4 (16/140) prevalansı ile en sık görülen kromozomal anomaliydi. İzole ve izole olmayan ASSA için karşılık gelen oranlar sırasıyla %3 (2/66) ve %18,9 (14/74) idi. İzole grupta %3 (n=2) DiGeorge sendromu ve %3 (n=2) Turner sendromu da saptandı. ASSA, trizomi 18’i olan 4 olgunun hiçbirinde izole bir bulgu değildi.

Sonuç: İzole ASSA, trizomi 21’in veya DiGeorge veya Turner sendromu dahil diğer kromozomal anomalilerin tek antenatal prediktörü olabilir. Bu nedenle, sağ subklavyen arterin görselleştirilmesi fetal anatominin incelenmenin bir parçası olmalı ve ilişkili bulguların yokluğunda bile genetik analiz önerilmelidir.

Anahtar Kelimeler: Aberrant right subclavian artery, DiGeorge syndrome, Down syndrome, Turner syndrome, prenatal diagnosis

Introduction

Aberrant right subclavian artery (ARSA) is the most common congenital abnormality of the aortic arch with a frequency of 1-1.5% in an apparently healthy population\(^1-3\). In normal anatomy, the right subclavian artery originates from the brachiocephalic trunk, one of the three main branches of the aortic arch. In contrast, ARSA is an anatomic variation in which the right subclavian artery originates from the aortic arch directly as an additional artery, usually distal to the left subclavian artery. It must course from the left side to right of the arch and ductus arteriosus, and passing behind the trachea to the opposite side. In all patients with a diagnosis of ARSA, detailed fetal anatomical scanning and echocardiography were performed to look for additional abnormal ultrasound findings. The cases of ARSA were divided into two groups as isolated if ARSA was the only antenatal sonographic finding in the 2nd or 3rd trimester, and non-isolated, those with concomitant sonographic findings including cardiac or extracardiac abnormalities and soft markers. Nuchal fold thickness, aplasia or hypoplasia of nasal bone, echogenic intracardiac focus, hyperechogenic bowel, mild pyelectasis, and short femur (<5\(^{th}\) percentile) were accepted as soft markers. Extracardiac abnormalities referred to all abnormal sonographic findings including fetal growth restriction, except for cardiac anomalies. Fetal biometric measurements were made according to Hadlock nomograms and estimated fetal weight (EFW) was calculated with the Hadlock formula. Those with abdominal circumference (AC)/EFW <3\(^{rd}\) percentile or absent-reverse end-diastolic flow in the umbilical artery or AC/EFW <10\(^{th}\) percentile combined with a pulsatility index >95\(^{th}\) percentile in either the umbilical or uterine artery were considered to have an intrauterine growth restriction\(^4-10\).

Prenatal invasive diagnostic tests for karyotype analysis including fluorescence in situ hybridization (FISH) analysis were proposed in each case of ARSA. Blood samples were taken in the postnatal period for genetic analysis from infants whose parents did not accept the antenatal invasive test. The presence of ARSA in all cases was confirmed through postnatal echocardiography or computed tomography. Cases without prenatal or postnatal genetic diagnostic tests and postnatal confirmation were excluded from the study.

Statistical Analysis

We used the IBM SPSS 21.0 for Windows (SPSS Inc., Chicago, IL, USA) statistical package for the statistical evaluation of our...
research data. The measured variables are presented as mean ± standard deviation and categorical variables are presented as numbers and percentages (%). The Kolmogorov-Smirnov test was used to determine whether the numerical data matched normal distribution. The Student’s t-test and Mann-Whitney U test were used to compare the groups. A p-value <0.05 was considered to be statistically significant.

Results

The anatomic screening data of a total of 11,666 fetuses were assessed and ARSA was identified in 140 fetuses over the study period. The antenatal prevalence of ARSA in our study was 1.2%. ARSA was diagnosed in the second trimester in 92/140 (65.7%) patients and the third trimester in 48/140 (34.3%) patients. At the time of diagnosis, the mean gestational age was 22.3±4.5 weeks, and the mean maternal age was 31.2±5.5 years. ARSA appeared isolated in 47.1% (66/140) of cases and it was found to be associated with a cardiac or extracardiac abnormal finding and/or a soft marker in the remaining 52.9% (74/140). Cardiac anomalies, extracardiac malformations, and soft markers were detected in 21.6% (16/74), 51.3% (38/74), and 40.5% (30/74) of cases, respectively. Some of the fetuses had more than one type of abnormal finding (e.g. cardiac and/or extracardiac anomalies and soft markers in the same fetus).

Antenatal screening tests were performed in 97/140 (69.2%) patients, including 57 first-trimester screening, 18 triple tests, and 22 quadruple tests. In 24 of these patients, cell-free fetal DNA screening was also performed.

Prenatal invasive diagnostic tests and karyotype analysis using FISH were performed in 88/140 cases. Sampling was performed by amniocentesis in 65/88 cases, cordocentesis in 13/88, and chorionic villus biopsy in the remaining 10/88 cases. Postnatal genetic examinations were performed in the remaining 52/140 cases. Chromosomal abnormalities were detected in 17.8% (25/140) of all cases. The corresponding rate was 9% (6/66) and 25.6% (19/74) for isolated and non-isolated ARSA, respectively. Trisomy 21 was the most common chromosomal anomaly with a prevalence of 11.4% (16/140). The corresponding rate was 3% (2/66) and 18.9% (14/74) for isolated and non-isolated ARSA, respectively. The other chromosomal anomalies were trisomy 18, 22q11.2 deletion (DiGeorge syndrome), and Turner syndrome. The distribution of chromosomal abnormalities in fetuses with ARSA is shown in Table 1.

The list of sonographic findings observed in fetuses with non-isolated ARSA is shown in Table 2. The most common cardiac anomaly associated with ARSA was a ventricular septal defect (n=6, 4.2%), and the most common extracardiac finding and soft marker was fetal growth restriction (n=8, 5.7%) and echogenic cardiac focus (n=12, 8.5%), respectively.

Details of cases with a chromosomal abnormality are presented in Table 3.

Table 1. Distribution of chromosomal abnormalities in fetuses with ARSA by gestational age and maternal age

|                | Isolated (n=66) | Non-isolated (n=74) | Total (n=140) |
|----------------|-----------------|---------------------|---------------|
| Mean GA at diagnosis, weeks (SD) | 21.6±4.2 | 23.4±2.8 | 22.3±4.5 |
| Mean maternal age, years (SD) | 32.3±5.3 | 31.4±5.1 | 31.2±5.5 |
| Maternal age ≥35 | 21 (31.8) | 20 (27) | 41 (29.2) |
| Trisomy 21 * | 2 (3) | 14 (18.9) | 16 (11.4) |
| DiGeorge syndrome | 2 (3) | 1 (1.3) | 3 (2.1) |
| Turner syndrome | 2 (3) | None | 2 (1.4) |
| Trisomy 18 | None | 4 (5.4) | 4 (2.8) |
| All anomalies ** | 6 (9) | 19 (25.6) | 25 (17.8) |

*p<0.024, ** p<0.003, p>0.05 for all other parameters. Percentage values are shown in parentheses, Student’s t-test, Mann-Whitney U test, ARSA: Aberrant right subclavian artery

Discussion

Previous studies revealed the prevalence rate of ARSA ranging between 0.4% and 2% among the general population\(^3\,10\,15\). Our study is one of the largest on ARSA in the literature and we identified 140 cases of ARSA with a prevalence rate of 1.2%. During the last decade, many studies in the literature investigated isolated or non-isolated ARSA with additional abnormalities and its relationship with chromosomal anomalies\(^9\). Esmer et al.\(^8\) first reported 14 trisomy-21 cases between 18 and 33 weeks of gestation and ARSA was detected in 5/14 (35.7%). In one of these cases, ARSA was the only abnormal ultrasound finding. Gul et al.\(^9\) also reported 17 cases of ARSA and only one case was diagnosed with trisomy 21. ARSA was the only ultrasound finding in this fetus. Similarly, Borenstein et al.\(^10\) published a case series of 8 fetuses with Down syndrome with ARSA, and in one of them, the ARSA was isolated. Zalel et al.\(^16\) reported three cases of ARSA in eight fetuses with Down syndrome, but none of these cases was isolated. In another large study, Svirsky et al.\(^17\) found a high prevalence of trisomy 21 in fetuses with ARSA, but none in the isolated group.

In our study, we demonstrated 16 cases of trisomy-21 in fetuses with ARSA and two were in the isolated group. Paladini et al.\(^18\) reported a case series of 27 fetuses with ARSA and Down syndrome and ARSA was an isolated sonographic finding in eight (29.6%). In this study, the authors suggested that in addition to nasal bone aplasia/hypoplasia and nuchal fold thickness, ARSA should be one of the most important ultrasound markers of Down syndrome in the 2nd trimester. In 2006, Chaoui et al.\(^10\) reported the prevalence of ARSA in fetuses with major chromosomal abnormalities as 34% (16/47). Ratios were found as 28.5% (4/14), 55.5% (5/9), and 50% (2/4) in trisomy 21, trisomy 18, and trisomy 13, respectively. Also, ARSA was detected at a rate of 43% (3/7) in Turner syndrome and 14% (1/7) in DiGeorge syndrome. ARSA was not the only ultrasound finding in any of these cases.
Table 2. Sonographic findings of fetuses with non-isolated ARSA in second or third trimester (some of the fetuses had more than one abnormal finding)

| Cardiac anomalies                  | n (%) | Extracardiac findings                  | n (%) | Soft markers                        | n (%) |
|-----------------------------------|-------|----------------------------------------|-------|-------------------------------------|-------|
| Ventricular septal defect         | 6 (4.2) | Fetal growth restriction               | 8 (5.7) | Echogenic Intracardiac focus       | 12 (8.5) |
| Coarctation of aorta              | 3 (2.1) | Ventriculomegaly                       | 7 (5)  | Mild pyelectasis                    | 8 (5.7) |

| 14   | 28           | 20+3            | Positive (cfDNA)  | None            | None                 | Mild pyelectasis | Trisomy 21 |
Although the relationship between ARSA and Down syndrome has been demonstrated, there are conflicting data in the literature regarding the association of isolated ARSA and trisomy 21 or other chromosomal abnormalities to recommend karyotyping\textsuperscript{(20)}. Rembouskos et al.\textsuperscript{(21)} detected DiGeorge syndrome in a case of ARSA with only increased NT as an additional finding and emphasized the addition of FISH analysis for microdeletion syndromes to fetal karyotyping, even if ARSA was the only ultrasound finding on the second or third trimester. We detected three cases with 22q11 deletion and in two of them, ARSA was the only ultrasound finding in the second or third trimester.

We detected three cases with 22q11 deletion and in two of them, ARSA was the only ultrasound finding in the second-trimester fetal anatomic survey and one case with DORV and thymic hypoplasia.

Aortic arch abnormalities can be observed in Turner syndrome. However, there are limited data in the literature about the relationship between Turner syndrome and ARSA. In a study with 99 patients with Turner syndrome, ARSA was reported in 8\% of cases\textsuperscript{(22)}.

ARSA was the only ultrasound finding in the second-trimester fetal anatomic screening in two fetuses in which we found Turner syndrome. Antenatal screening tests were not performed in one of the cases, but the other had increased nuchal translucency at the first-trimester screening.

### Conclusion

ARSA may be the only ultrasound finding in trisomy 21 and also in DiGeorge and Turner syndrome in the second or third trimester. Hence, imaging the right subclavian artery should be part of the fetal anatomical survey and standard karyotyping and FISH analysis should be recommended, even in isolated ARSA, especially in patients who do not have antenatal screening tests.
