FINITE-PARTICLE APPROXIMATIONS FOR INTERACTING BROWNIAN PARTICLES WITH LOGARITHMIC POTENTIALS

YOSUKE KAWAMOTO, HIROFUMI OSADA

Abstract. We prove the convergence of $N$-particle systems of Brownian particles with logarithmic interaction potentials onto a system described by the infinite-dimensional stochastic differential equation (ISDE). For this proof we present two general theorems on the finite-particle approximations of interacting Brownian motions. In the first general theorem, we present a sufficient condition for a kind of tightness of solutions of stochastic differential equations (SDE) describing finite-particle systems, and prove that the limit points solve the corresponding ISDE. This implies, if in addition the limit ISDE enjoy a uniqueness of solutions, then the full sequence converges. We treat non-reversible case in the first main theorem. In the second general theorem, we restrict to the case of reversible particle systems and simplify the sufficient condition. We deduce the second theorem from the first. We apply the second general theorem to Airy$_\beta$ interacting Brownian motion with $\beta = 1, 2, 4$, and the Ginibre interacting Brownian motion. The former appears in the soft-edge limit of Gaussian (orthogonal/unitary/symplectic) ensembles in one spatial dimension, and the latter in the bulk limit of Ginibre ensemble in two spatial dimensions, corresponding to a quantum statistical system for which the eigen-value spectra belong to non-Hermitian Gaussian random matrices. The passage from the finite-particle stochastic differential equation (SDE) to the limit ISDE is a sensitive problem because the logarithmic potentials are long range and unbounded at infinity. Indeed, the limit ISDEs are not easily detectable from those of finite dimensions. Our general theorems can be applied straightforwardly to the grand canonical Gibbs measures with Ruelle-class potentials such as Lennard-Jones 6-12 potentials and and Riesz potentials.

1. Introduction

Interacting Brownian motion in infinite dimensions is prototypical of diffusion processes of infinitely many particle systems, initiated by Lang [12, 13], followed by Fritz [3], Tanemura [30], and others. Typically, interacting Brownian motion $X = (X^i)_{i \in \mathbb{N}}$ with Ruelle-class (translation invariant) interaction $\Psi$ and inverse temperature $\beta \geq 0$ is given by

$$dX^i_t = dB^i_t - \frac{\beta}{2} \sum_{j \neq i} \nabla \Psi(X^i_t - X^j_t) dt \quad (i \in \mathbb{N}).$$

(1.1)

Here an interaction $\Psi$ is called Ruelle-class if $\Psi$ is super stable in the sense of Ruelle, and integrable at infinity [28].

The system $X$ is a diffusion process with state space $S_0 \subset (\mathbb{R}^d)^\mathbb{N}$, and has no natural invariant measures. Indeed, such a measure $\hat{\mu}$, if exists, is informally given by

$$\hat{\mu} = \frac{1}{Z} e^{-\beta \sum_{i,j} \Psi(x_i - x_j)} \prod_{k \in \mathbb{N}} dx_k,$$

(1.2)

which cannot be justified as it is because of the presence of an infinite product of Lebesgue measures. To rigorize the expression (1.2), the Dobrushin–Lanford–Ruelle (DLR) framework introduces the notion of a Gibbs measure. A point process $\mu$ is called a $\Psi$-canonical Gibbs measure if it satisfies the DLR equation: for each $m \in \mathbb{N}$ and $\mu$-a.s. $\xi = \sum_i \delta_{\xi_i}$,

$$\mu^m_{r,\xi}(ds) = \frac{1}{Z_{r,\xi}} e^{-\beta \sum_{i \in m} \Psi(s_i - s_j) + \sum_{i \in m} \Psi(s_i - \xi_j)} \prod_{k=1}^m ds_k,$$

(1.3)
where \( s = \sum_i \delta_{s_i}, \ S_r = \{ |x| \leq r \}, \ \pi_r(s) = s(\cap S_r), \) and \( \xi \) is the outer condition. Furthermore, \( \mu_{r, \xi}^n \) denotes the regular conditional probability:

\[
\mu_{r, \xi}^n(ds) = \mu(\pi_r(s) \in ds | s(S_r) = m, \ \pi_r^* = \pi_r^*(\xi)).
\]

Then \( \mu \) is a reversible measure of the delabeled dynamics \( X \) such that \( X_t = \sum_{i \in \mathbb{N}} \delta_{X_t^i} \).

If the number of particles is finite, \( N \) say, then SDE (1.1) becomes

\[
dX^{N,i}_t = dB_t - \frac{\beta}{2} \{ \nabla \Phi^N(X^{N,i}_t) + \sum_{j \neq i}^N \nabla \Psi(X^{N,i}_t - X^{N,j}_t) \} dt \quad (1 \leq i \leq N),
\]

where \( \Phi^N \) is a confining free potential vanishing zero as \( N \) goes to infinity. The associated labeled measure is then given by

\[
\hat{\mu}^N = \frac{1}{2} e^{-\beta (\sum_{i=1}^N \Phi^N(x_i) + \sum_{i<j} \Psi(x_i - x_j))} \prod_{k=1}^N dx_k.
\]

The relation between (1.4) and (1.5) is as follows. We first consider the diffusion process associated with the Dirichlet form with domain \( D^\mu_N \) on \( L^2((\mathbb{R}^d)^N, \hat{\mu}^N) \), called the distorted Brownian motion, such that

\[
\mathcal{E}^\mu_N(f, g) = \int_{(\mathbb{R}^d)^N} \frac{1}{2} \sum_{i=1}^N \nabla_i f \cdot \nabla_i g \hat{\mu}^N(dx_i),
\]

where \( \nabla_i = (\frac{\partial}{\partial x_{ij}})_{j=1}^d, \ x_N = (x_1, \ldots, x_N) \in (\mathbb{R}^d)^N, \) and \( \cdot \) denotes the inner product in \( \mathbb{R}^d \). The generator \( -L^\mu_N \) of \( \mathcal{E}^\mu_N \) is then given by

\[
\mathcal{E}^\mu_N(f, g) = (-L^\hat{\mu}_N f, g)_{L^2((\mathbb{R}^d)^N, \hat{\mu}^N)}.
\]

Integration by parts yields the representation of the generator of the diffusion process such that

\[
L^\hat{\mu}_N = \frac{1}{2} \Delta - \frac{\beta}{2} \sum_{i=1}^N \{ \nabla \Phi^N(x_i) + \sum_{j \neq i}^N \nabla \Psi(x_i - x_j) \} \cdot \nabla_i,
\]

which together with Itô formula yields SDE (1.4).

For a finite or infinite sequence \( x = (x_i) \), we set \( u(x) = \sum_i \delta_{x_i} \), and call \( u \) a delabeling map. For a point process \( \mu \), we say a measurable map \( \ell = \ell(s) \) defined for \( \mu \)-a.s. \( s \) with value \( S^\infty \cup \{ \cup_{N=1}^\infty S^N \} \) is called a label with respect to \( \mu \) if \( u \circ \ell(s) = s \). Let \( \ell_N \) be a label with respect to \( \mu^N \). We denote by \( \ell_m \) and \( \ell_{N,m} \) the first \( m \)-components of these labels, respectively. We take \( \Phi^N \) such that the associated point process \( \mu^N = \mu^N \circ u^{-1} \) converges weakly to \( \mu \):

\[
\lim_{N \to \infty} \mu^N = \mu \quad \text{weakly}.
\]

The associated delabeling \( X^N = \sum_{i=1}^N \delta_{X^N_i} \), is reversible with respect to \( \mu^N \). The labeled process \( X = (X^N) \) and \( X^N = (X^{N,i}) \) can be recovered from \( X \) and \( X^N \) by taking suitable initial labels \( \ell \) and \( \ell_N \), respectively. Choosing the labels in such a way that for each \( m \in \mathbb{N} \)

\[
\lim_{N \to \infty} \mu^N \circ \ell_{-1}^{-1} = \mu \circ \ell_{-1}^{-1} \quad \text{weakly},
\]

we have the convergence of labeled dynamics \( X^N \) to \( X \) such that for each \( m \)

\[
\lim_{N \to \infty} (X^{N,1}, \ldots, X^{N,m}) = (X^1, \ldots, X^m) \quad \text{in law in} \ C([0, \infty); (\mathbb{R}^d)^m).
\]

We expect this convergence because of the absolute convergence of the drift terms in (1.4) and energy in the DLR equation (1.3) for well-behaved initial distributions although it still requires some work to justify this rigorously even if \( \Psi \in C^3_0(\mathbb{R}^d) \) [12].
If we take logarithmic functions as interaction potentials, then the situation changes drastically. Consider the soft-edge scaling limit of Gaussian (orthogonal/unitary/symplectic) ensembles. Then the $N$-labeled density is given by

$$\rho_{\text{Airy}, \beta}^N(dx_N) = \frac{1}{Z} \prod_{i<j}^N |x_i - x_j|^{\beta} \exp \left\{-\frac{\beta}{4} \sum_{k=1}^N |2\sqrt{N} + N^{-1/6}x_k|^2 \right\} dx_N$$

and the associated $N$-particle dynamics described by SDE

$$dX_t^{N,i} = dB_t^i + \frac{\beta}{2} \sum_{j=1, j \neq i}^N \frac{1}{X_t^{N,i} - X_t^{N,j}} dt - \frac{\beta}{2} \left\{ N^{1/3} + \frac{1}{2N^{1/3}} X_t^{N,i} \right\} dt.$$

The correspondence between (1.9) and (1.10) is transparent and same as above. Indeed, we first consider distorted Brownian motion (Dirichlet spaces with $\beta > 0$) [27]. Its $m$-point correlation function is explicitly given as a determinant of certain kernels if $\beta = 1, 2, 4$ [11, 15]. Indeed, if $\beta = 2$, then the $m$-point correlation function of the limit point process $\rho_{\text{Airy}, 2}$ is

$$\rho_{\text{Airy}, 2}^m(x_m) = \det[K_{\text{Ai}, 2}(x_i, x_j)]_{i,j=1}^m,$$

where $K_{\text{Ai}, 2}$ is the continuous kernel such that, for $x \neq y$,

$$K_{\text{Ai}, 2}(x, y) = \frac{\text{Ai}(x)\text{Ai}'(y) - \text{Ai}'(x)\text{Ai}(y)}{x - y}.$$

We set here $\text{Ai}'(x) = d\text{Ai}(x)/dx$ and denote by $\text{Ai}(\cdot)$ the Airy function given by

$$\text{Ai}(z) = \frac{1}{2\pi} \int_{\mathbb{R}} dk e^{ik(z + k^3/3)}, \quad z \in \mathbb{R}.$$

For $\beta = 1, 4$ similar expressions in terms of the quaternion determinant are known [11, 15].

From the convergence of equilibrium states, we may expect the convergence of solutions of SDEs (1.10). The divergence of the coefficients in (1.10) and the very long-range nature of the logarithmic interaction however prove to be problematic. Even an informal representation of the limit coefficients is nontrivial but has been obtained in [26]. Indeed, the limit ISDEs are given by

$$dX_t^i = dB_t^i + \frac{\beta}{2} \lim_{r \to 0} \frac{1}{|X_t^i - X_t^j|} \int_{|x| < r} \frac{g(x)}{x - X_t^i} dx dt \quad (i \in \mathbb{N}).$$

Here $g(x) = 1_{(0, \infty)}(x)\sqrt{\frac{\pi}{x}}$, which is the shifted and rescaled semicircle function at the right edge.

As an application of our main theorem (Theorem 2.2), we prove the convergence (1.8) to (1.11) for $\rho_{\text{Airy}, \beta}^N$ with $\beta = 2$. We also prove that the limit points of solutions of (1.10) satisfy ISDE (1.11) with $\beta = 1, 2, 4$.

For general $\beta \neq 1, 2, 4$, the existence and uniqueness of solutions of (1.11) is still an open problem. Indeed, the proof in [26] relies on a general theory developed in [18, 19, 20, 21, 25], which reduces the problem to the quasi-Gibbs property and the existence of the logarithmic derivative of the equilibrium state. These key properties are proved only for $\beta = 1, 2, 4$ at present. We refer to [20, 21] for the definition of the quasi-Gibbs property and Definition 2.1 for the logarithmic derivative.

Another typical example is the Ginibre interacting Brownian motion, which is an infinite-particle system in $\mathbb{R}^2$ (naturally regarded as $\mathbb{C}$), whose equilibrium state is the Ginibre point process $\mu_{\text{Gin}}$. The $m$-point correlation function $\rho_{\text{Gin}}^m$ with respect to Gaussian measure $(1/\pi)e^{-|x|^2} dx$ on $\mathbb{C}$ is then given by

$$\rho_{\text{Gin}}^m(x_m) = \det[e^{x_i\bar{x}_j}]_{i,j=1}^m.$$

Finite-particle approximations for interacting Brownian particles with logarithmic potentials.
The Ginibre point process $\mu_{\text{gin}}$ is the thermodynamic limit of $N$-particle point process $\mu_{\text{gin}}^N$ whose labeled measure is given by

$$
\mu_{\text{gin}}^N(dx_N) = \frac{1}{Z} \prod_{i<j}^N |x_i - x_j|^2 e^{-\sum_{i=1}^N |x_i|^2} \, dx_N.
$$

The associated $N$-particle SDE is then given by

$$
dX_i^N, t = dB_i^t - X_i^N, t \, dt + \sum_{j=1,j\neq i}^N \frac{X_i^N, t - X_j^N, t}{|X_i^N, t - X_j^N, t|^2} \, dt \quad (1 \leq i \leq N).
$$

We shall prove that the limit ISDEs are

$$
dX_i^t = dB_i^t + \lim_{r \to \infty} \sum_{|x_j - x_i| < r, j \neq i} \frac{X_i^t - X_j^t}{|X_i^t - X_j^t|^2} \, dt \quad (i \in \mathbb{N}) \quad (1.13)
$$

and

$$
dX_i^t = dB_i^t - X_i^t \, dt + \lim_{r \to \infty} \sum_{|x_j - x_i| < r, j \neq i} \frac{X_i^t - X_j^t}{|X_i^t - X_j^t|^2} \, dt \quad (i \in \mathbb{N}). \quad (1.14)
$$

In [19, 25], it is proved that these ISDEs have the same pathwise unique strong solution for $\mu_{\text{gin}} \circ \ell^{-1}$-a.s. $s$, where $\ell$ is a label and $s$ is an initial point. As an example of applications of our second main theorem (Theorem 2.2), we prove the convergence of solutions of (1.12) to those of (1.13) and (1.14). This example indicates again the sensitivity of the representation of the limit ISDE. Such varieties of the limit ISDEs are a result of the long-range nature of the logarithmic potential.

The main purpose of the present paper is to develop a general theory for finite-particle convergence applicable to logarithmic potentials, and in particular, the Airy and Ginibre point processes. Our theory is also applicable to essentially all Gibbs measures with Ruelle-class potentials such as the Lennard-Jones 6-12 potential and Riesz potentials.

In the first main theorem (Theorem 2.1), we present a sufficient condition for a kind of tightness of solutions of stochastic differential equations (SDE) describing finite-particle systems, and prove that the limit points solve the corresponding ISDE. This implies, if in addition the limit ISDE enjoy uniqueness of solutions, then the full sequence converges. We treat non-reversible case in the first main theorem.

In the second main theorem (Theorem 2.2), we restrict to the case of reversible particle systems and simplify the sufficient condition. Because of reversibility, the sufficient condition is reduced to the convergence of logarithmic derivative of $\mu^N$ with marginal assumptions. We shall deduce Theorem 2.2 from Theorem 2.1 and apply Theorem 2.2 to all examples in the present paper.

If $\Psi(x) = -\log |x|$, $\beta = 2$ and $d = 1$, there exists an algebraic method to construct the associated stochastic processes [7, 8, 9, 10], and to prove the convergence of finite-particle systems [21, 23, 25]. This method requires that interaction $\Psi$ is the logarithmic function with $\beta = 2$ and depends crucially on an explicit calculation of space-time determinantal kernels. It is thus not applicable to $\beta \neq 2$ even if $d = 1$.

As for Sine$_\beta$ point processes, Tsai proved the convergence of finite-particle systems for all $\beta \geq 1$ [31]. His method relies on a coupling method based on monotonicity of SDEs, which is very specific to this model.

The organization of the paper is as follows: In Section 2, we state the main theorems (Theorem 2.1 and Theorem 2.2). In Section 3, we prove Theorem 2.1. In Section 4, we prove Theorem 2.2 using Theorem 2.1. In Section 5, we present examples.
2. Set up and the main theorems

2.1. Configuration spaces and Campbell measures. Let $S$ be a closed set in $\mathbb{R}^d$ whose interior $S_{\text{int}}$ is a connected open set satisfying $\overline{S_{\text{int}}} = S$ and the boundary $\partial S$ having Lebesgue measure zero. A configuration $s = \sum_i \delta_{s_i}$ on $S$ is a Radon measure on $S$ consisting of delta masses. We set $S_r = \{ s \in S ; |s| \leq r \}$. Let $S$ be the set consisting of all configurations of $S$. By definition, $S$ is given by

$$S = \{ s = \sum_i \delta_{s_i} ; s(S_r) < \infty \text{ for each } r \in \mathbb{N} \}.$$ 

By convention, we regard the zero measure as an element of $S$. We endow $S$ with the vague topology, which makes $S$ a Polish space. $S$ is called the configuration space over $S$ and a probability measure $\mu$ on $(S, \mathcal{B}(S))$ is called a point process on $S$.

A symmetric and locally integrable function $\rho^n : S^n \to [0, \infty)$ is called the $n$-point correlation function of a point process $\mu$ on $S$ with respect to the Lebesgue measure if $\rho^n$ satisfies

$$\int_{A_1 \times \cdots \times A_m} \rho^n(x_1, \ldots, x_n)dx_1 \cdots dx_n = \int_S \prod_{i=1}^m \frac{s(A_i)!}{s(A_i) - k_i)!}d\mu$$

for any sequence of disjoint bounded measurable sets $A_1, \ldots, A_m \in \mathcal{B}(S)$ and a sequence of natural numbers $k_1, \ldots, k_m$ satisfying $k_1 + \cdots + k_m = n$. When $s(A_i) - k_i < 0$, according to our interpretation, $s(A_i)!/(s(A_i) - k_i)! = 0$ by convention. Hereafter, we always consider correlation functions with respect to Lebesgue measures.

A point process $\mu_x$ is called the reduced Palm measure of $\mu$ conditioned at $x \in S$ if $\mu_x$ is the regular conditional probability defined as

$$\mu_x = \mu(\cdot - \delta_x|s(\{x\}) \geq 1).$$

A Radon measure $\mu^{[1]}$ on $S \times S$ is called the 1-Campbell measure of $\mu$ if $\mu^{[1]}$ is given by

$$(2.1) \quad \mu^{[1]}(dxds) = \rho^1(x)\mu_x(ds)dx.$$ 

2.2. Finite-particle approximations (general case). Let $\{\mu^N\}$ be a sequence of point processes on $S$ such that $\mu^N(\{s(S) = N\}) = 1$. We assume:

(H1) Each $\mu^N$ has a correlation function $\{\rho^{N,n}\}$ satisfying for each $r \in \mathbb{N}$

$$(2.2) \quad \lim_{N \to \infty} \rho^{N,n}(x) = \rho^n(x) \quad \text{uniformly on } S^n_r \text{ for all } n \in \mathbb{N},$$

$$(2.3) \quad \sup_{N \in \mathbb{N}} \sup_{x \in S^n_r} \rho^{N,n}(x) \leq c_2(r) c_2^{-1}.$$

where $0 < c_1(r) < \infty$ and $0 < c_2(r) < 1$ are constants independent of $n \in \mathbb{N}$.

It is known that $2.2$ and $2.3$ imply weak convergence $\text{[10]} \text{[20]}$ Lemma A.1. As in Section $\text{[11]}$ let $\ell$ and $\ell_N$ be labels of $\mu$ and $\mu^N$, respectively. We assume:

(H2) For each $m \in \mathbb{N}$, $\text{[17]}$ holds. That is,

$$(2.4) \quad \lim_{N \to \infty} \mu^N \circ \ell_N^{-1} = \mu \circ \ell^{-1} \quad \text{weakly in } S^m.$$

We shall later take $\mu^N \circ \ell_N^{-1}$ as an initial distribution of a labeled finite-particle system. Hence $\text{H2}$ means convergence of the initial distribution of the labeled dynamics. There exist infinitely many different labels $\ell$, and we choose a label such that the initial distribution of the labeled dynamics converges. $\text{H2}$ will be used in Theorem $2.2$ and Theorem $2.1$.

For $X = (X^i)_{i=1}^\infty$ and $X^N = (X^{N,i})_{i=1}^N$, we set

$$X^i_{\ell^1} = \sum_{j \neq i} \delta_{X^i_j}, \quad \text{and} \quad X^N_{\ell^1} = \sum_{j \neq i} \delta_{X^{N,i}_j},$$
where $X^{N,\cdot_i}$ denotes the zero measure for $N = 1$. Let $\sigma^N, \sigma : S \times S \to \mathbb{R}^d$ and $b^N, b : S \times S \to \mathbb{R}^d$ be measurable functions. We introduce the finite-dimensional SDE of $X^N = (X^N_{\cdot,i})_{i=1}^N$ with these coefficients such that for $1 \leq i \leq N$

\[
(2.4) \quad dX^N_{t,i} = \sigma^N(X^N_{t,i}, X^{N,\cdot_i}) dB^i_t + b^N(X^N_{t,i}, X^{N,\cdot_i}) dt
\]

(2.5) $X^N_0 = s$.

We assume:

(2) SDE (2.4) and (2.5) has a unique solution for $\mu^N \circ \ell^{-1}_{N,1} \text{-a.s.}$, $s$ for each $N$: this solution does not explode. Furthermore, when $\partial S$ is non-void, particles never hit the boundary.

We set $a^N = \sigma^N \sigma^N$ and assume:

(4) $a^N$ are bounded and continuous on $S \times S$, and converge uniformly to $a$ on $S_r \times S$ for each $r \in \mathbb{N}$. Furthermore, $a^N$ are uniformly elliptic on $S_r \times S$ for each $r \in \mathbb{N}$ and $\nabla_x a^N$ are uniformly bounded on $S \times S$.

From (4) we see that $a^N$ converge uniformly to $a := \sigma^R \sigma$ on each compact set $S_r \times S$, and that $a^N$ and $a$ are bounded and continuous on $S \times S$. There thus exists a positive constant $c_3$ such that

\[
(2.6) \quad \|a\|_{S \times S}, ||\nabla_x a||_{S \times S}, \sup_{N \in \mathbb{N}} ||a^N||_{S \times S}, \sup_{N \in \mathbb{N}} ||\nabla_x a^N||_{S \times S} \leq c_3.
\]

Here $\cdot \cdot S \times S$ denotes the uniform norm on $S \times S$. Furthermore, we see that $a$ is uniformly elliptic on each $S_r \times S$. From these, we expect that SDEs (2.4) have a sub-sequential limit.

\[
\lim_{N \to \infty} \{X^N_{t,i} - X^N_{0,i}\} = \lim_{N \to \infty} \int_0^t \sigma^N(X^N_{t,i}, X^{N,\cdot_i}) dB^i_u + \lim_{N \to \infty} \int_0^t b^N(X^N_{t,i}, X^{N,\cdot_i}) du
\]

\[
= \int_0^t \sigma(X^N_{t,i}, X^{N,\cdot_i}) dB^i_u + \lim_{N \to \infty} \int_0^t b^N(X^N_{t,i}, X^{N,\cdot_i}) du.
\]

To identify the second term on the right-hand side and to justify the convergence, we make further assumptions. As the examples in Section 1 suggest, the identification of the limit is a sensitive problem, which is at the heart of the present paper.

We set the maximal module variable $X^{N,m}$ of the first $m$-particles by

\[
X^{N,m} = \max_{i=1}^m \sup_{t \in [0,T]} |X^N_{t,i}|.
\]

and by $\ell^N_r$ the maximal label with which the particle intersects $S_r$; that is,

\[
\ell^N_r = \max \{i \in \mathbb{N} \cup \{\infty\}; |X^N_{t,i}| \leq r \text{ for some } 0 \leq t \leq T\}.
\]

We assume the following.

(I) For each $m \in \mathbb{N}$

\[
(2.7) \quad \lim_{u \to \infty} \liminf_{N \to \infty} P^{N,\ell^{-1}_{N,1}}(X^{N,m} \leq a) = 1
\]

and there exists a constant $c_4 = (4, m, a)$ such that for $0 \leq t, u \leq T$

\[
(2.8) \quad \sup_{N \in \mathbb{N}} \sum_{i=1}^m E^{N,\ell^{-1}_{N,1}}[|X^N_{t,i} - X^N_{u,i}|^4; X^{N,m} \leq a] \leq c_4 |t - u|^2.
\]

Furthermore, for each $r \in \mathbb{N}$

\[
(2.9) \quad \lim_{L \to \infty} \liminf_{N \to \infty} P^{N,\ell^{-1}_{N,1}}(\ell^N_r \leq L) = 1.
\]

Let $\mu^{N,[1]}$ be the one-Campbell measure of $\mu^N$ defined as (2.1). Set $c_5(r, N) = \mu^{N,[1]}(S_r \times S)$. Then by (2.5) $\sup_{N \in \mathbb{N}} c_5(r, N) < \infty$ for each $r \in \mathbb{N}$. Without loss of generality, we can assume that $c_5 > 0$ for all $r, N$. Let $\mu^{N,[1]} = \mu^{N,[1]}(\cdot \cap \{S_r \times S\})$. Let $\tilde{\mu}^{N,[1]}$ be the probability measure
defined as $\mu_r^{N,1} = (\mu_r^{N,1}(\cdot \cap \{S_r \times S\}))$.

Let $\pi_r,s$ be a map from $S_r \times S$ to itself such that $\pi_r,s(x,s) = (x, \sum_{|x-s| < s} \delta_{x,s})$, where $s = \sum_{|x-s| < s} \delta_{x,s}$. Let $\mathcal{F}_{r,s} = \sigma[\pi_{r,s}]$ be the sub-$\sigma$-field of $\mathcal{B}(S_r \times S)$ generated by $\pi_{r,s}$. Because $S_r$ is a subset of $S$, we can and do regard $\mathcal{F}_{r,s}$ as a $\sigma$-field on $S \times S$, which is trivial outside $S_r \times S$.

We set a tail-truncated coefficient $b_{r,s}^N$ of $b^N$ and their tail parts $b_{r,s}^{N,tail}$ by

\begin{equation}
    b_{r,s}^N = \mathbb{E}^{\mu_r^{N,1}}[b^N | \mathcal{F}_{r,s}], \quad b^N = b_{r,s}^N + b_{r,s}^{N,tail}.
\end{equation}

We can and do take a version of $b_{r,s}^N$ such that

\begin{align}
    b_{r,s}^N(x,y) &= 0 \quad \text{for } x \notin S_r, \quad (2.11) \\
    b_{r,s}^N(x,y) &= b_{r,s}^{N,1}(x,y) \quad \text{for } x \in S_r, \quad (2.12)
\end{align}

We next introduce a cut-off coefficient $b_{r,s,p}^N$ of $b_{r,s}^N$. Let $b_{r,s,p}^N$ be a continuous and $\mathcal{F}_{r,s}$-measurable function on $S \times S$ such that

\begin{align}
    b_{r,s,p}^N(x,y) &= 0 \quad \text{for } x \notin S_r, \quad (2.13) \\
    b_{r,s,p}^N(x,y) &= b_{r,s}^{N,1}(x,y) \quad \text{for } x \in S_{r-1}, \quad (2.14)
\end{align}

and that, for $(S \times S)_{r,p} = \{(x,y) \in S_r \times S; |x - y_i| \leq 1/2^p$ for some $y_i\}$, where $y = \sum_i \delta_{y_i},$

\begin{align}
    b_{r,s,p}^N(x,y) &= 0 \quad \text{for } (x,y) \in (S \times S)_{r,p+1}, \quad (2.15) \\
    b_{r,s,p}^N(x,y) &= b_{r,s}^N(x,y) \quad \text{for } (x,y) \notin (S \times S)_{r,p}. \quad (2.16)
\end{align}

The main requirements for $b^N$ and $b_{r,s,p}^N$ are the following:

**Claim (12)** There exists a $\tilde{p}$ such that $1 < \tilde{p} < \infty$ and that for each $r \in \mathbb{N}$

\begin{equation}
    \limsup_{N \to \infty} \int_{S \times S} |b^N|^\tilde{p} \, d\mu_r^{N,1} < \infty. \quad (2.17)
\end{equation}

Furthermore, for each $r, i \in \mathbb{N}$, there exists a constant $c_6$ such that

\begin{equation}
    \sup_{p \in \mathbb{N}} \sup_{N \in \mathbb{N}} \mathbb{E}_{\mu_r^{N,1}} \left[ \int_0^T |b_{r,s,p}^N(X_{r,i}^N, X_{s,i}^N, \sigma_i)|^p \, dt \right] \leq c_6. \quad (2.18)
\end{equation}

We set $S^m_r = \{s; S_r(s) = m\}$. Let $\| \cdot \|_{S \times S^m}$ denote the uniform norm on $S \times S^m$ and set $L^p(\mu_r^{N,1}) = L^p(S_r \times S, \mu_r^{N,1})$. For a function $f$ on $S \times S^m$ we denote by $\nabla f = (\nabla_x \hat{f}, \nabla_y \hat{f})$, where $\hat{f}$ is a function on $S_r \times S^m$ such that $\hat{f}(x, (y_i)_{i=1}^m) = f(x, (y_i)_{i=1}^m)$ is symmetric in $(y_i)_{i=1}^m$ for each $x$ and $f(x, \sum_i \delta_{y_i}) = f(x, (y_i)_{i=1}^m)$. We decompose $b_{r,s}^N$ as

\begin{equation}
    b_{r,s}^N = b_{r,s,p}^N + b_{r,s}^N - b_{r,s,p}^N \quad (2.19)
\end{equation}

and we assume:

**Claim (13)** For each $m, p, r, s \in \mathbb{N}$ such that $r < s$, there exists $b_{r,s,p}$ such that

\begin{equation}
    \lim_{N \to \infty} \|b_{r,s,p}^N - b_{r,s,p}\|_{S \times S^m} = 0. \quad (2.20)
\end{equation}

Moreover, $b_{r,s,p}^N$ are differentiable in $x$ and satisfying the bounds:

\begin{align}
    \sup_{N \in \mathbb{N}} \|\nabla b_{r,s,p}^N\|_{S \times S^m} &< \infty, \quad (2.21) \\
    \limsup_{N \to \infty} \sup_{N \in \mathbb{N}} \|b_{r,s,p}^N - b_{r,s}^N\|_{L^p(\mu_r^{N,1})} &< \infty. \quad (2.22)
\end{align}
Furthermore, we assume for each $i, r < s \in \mathbb{N}$

\begin{equation}
\lim_{p \to \infty} \limsup_{N \to \infty} E^{\mu^{N \circ \tau^{-1}}}_N \left[ \int_0^T |\{b_{r,s,p}^N - b_{r,s}^N\}(X^{N,i}_t, X^{r,i}_t)|^p dt \right] = 0, \tag{2.23}
\end{equation}

\begin{equation}
\lim_{p \to \infty} E^{\mu^{N \circ \tau^{-1}}}_N \left[ \int_0^T |\{b_{r,s,p} - b_{r,s}\}(X^i_t, X^{r,i}_t)|^p dt \right] = 0, \tag{2.24}
\end{equation}

where $b_{r,s}$ is such that

\begin{equation}
b_{r,s}(x, y) = \lim_{N \to \infty} b_{r,s}^N(x, y) \quad \text{for each } (x, y) \in \bigcup_{p \in \mathbb{N}} (S \times S)^c_{r,p}. \tag{2.25}
\end{equation}

**Remark 2.1.** We see that $\bigcup_{p \in \mathbb{N}} (S \times S)^c_{r,p} = \{S^c \times S\} \cup \{(x, y); x \neq y_i \text{ for all } i\}$ by definition and $b_{r,s}(x, y) = 0$ for $x \not\in S_r$ by (2.14). The limit in (2.25) exists because of (2.16), (2.19), and (2.24).

(I4) There exists a $b^\text{tail} \in C(S; \mathbb{R}^d)$ independent of $r \in \mathbb{N}$ and $s \in S$ such that

\begin{equation}
\lim_{s \to \infty} \limsup_{N \to \infty} \|b_{r,s}^{N,\text{tail}} - b^\text{tail}\|_{L^p(\mu^N_{r,(i)})} = 0. \tag{2.26}
\end{equation}

Furthermore, for each $r, i \in \mathbb{N}$

\begin{equation}
\lim_{s \to \infty} \limsup_{N \to \infty} E^{\mu^{N \circ \tau^{-1}}}_N \left[ \int_0^T |(b_{r,s}^{N,\text{tail}} - b^\text{tail})(X^{N,i}_t, X^{r,i}_t)|^p dt \right] = 0. \tag{2.27}
\end{equation}

We remark that $b^\text{tail}$ is automatically independent of $r$ for consistency (2.16). By assumption, $b^\text{tail} = b^\text{tail}(x)$ is a function of $x$. From (2.10) and (2.19) we have

\begin{equation}
b^N = b_{r,s,p}^N + b^\text{tail} + \{b_{r,s}^N - b_{r,s,p}^N\} + \{b_{r,s}^{N,\text{tail}} - b^\text{tail}\}. \tag{2.28}
\end{equation}

In (I3) and (I4), we have assumed that the last two terms $\{b_{r,s}^N - b_{r,s,p}^N\}$ and $\{b_{r,s}^{N,\text{tail}} - b^\text{tail}\}$ in (2.28) are asymptotically negligible.

Under these assumptions, we prove in Lemma 3.4 that there exists $b$ such that for each $r \in \mathbb{N}$

\begin{equation}
\lim_{s \to \infty} \|b_{r,s} - b\|_{L^p(\mu^N_{r,(i)})} = 0. \tag{2.29}
\end{equation}

We assume:

(I5) For each $i, r \in \mathbb{N}$

\begin{equation}
\lim_{s \to \infty} E^{\mu^{N \circ \tau^{-1}}}_N \left[ \int_0^T |(b_{r,s} - b)(X^i_t, X^{r,i}_t)|^p dt \right] = 0. \tag{2.30}
\end{equation}

We say a sequence $\{X^N\}$ of $C([0, T]; S^N)$-valued random variables is tight if for any subsequence we can choose a subsequence denoted by the same symbol such that $\{X^{N,m}\}_{N \geq m}$ is convergent in law in $C([0, T]; S^m)$ for each $m \in \mathbb{N}$. With these preparations, we state the main theorem in this section.

**Theorem 2.1.** Assume (H1)–(H4) and (I1)–(I5). Then, $\{X^N\}_{N \in \mathbb{N}}$ is tight in $C([0, T]; S^N)$ and, any limit point $X = (X^i)_{i \in \mathbb{N}}$ of $\{X^N\}_{N \in \mathbb{N}}$ is a solution of the ISDE

\begin{equation}
dx^i_t = \sigma(X^i_t, X^{r,i}_t)dB^i_t + \{b(X^i_t, X^{r,i}_t) + b^\text{tail}(X^i_t)\}dt. \tag{2.31}
\end{equation}

**Remark 2.2.** If diffusion processes are symmetric, we can dispense with (2.8), (2.18), (2.28), (2.24), (2.27), and (2.30) as we see in Subsection 2.3. Indeed, using the Lyons-Zheng decomposition we can derive these from static conditions (H4), (2.17), (2.20), (2.22), (2.26), and (2.29). We remark that we can apply Theorem 2.1 to non-symmetric diffusion processes by assuming these dynamical conditions.
2.3. Finite-particle approximations (reversible case). For a subset $A$, we set $\pi_A : S \to S$ by $\pi_A(s) = s \cap A$. We say a function $f$ on $S$ is local if $f$ is $\sigma([K])$-measurable for some compact set $K$ in $S$. For a local function $f$ on $S$, we say $f$ is smooth if $f$ is smooth, where $\bar{f}(x_1, \ldots)$ is a symmetric function such that $\bar{f}(x_1, \ldots) = f(x)$ for $x = \sum \delta_{x_i}$. Let $\mathcal{D}_t$ be the set of all bounded, local smooth functions on $S$. We write $f \in L^p(S, \mu)$ if $f \in L^p(S, \mu)$ for all $r \in N$. Let $C^0_0(S) \otimes \mathcal{D}_t = \{ \sum_{i=1}^N f_i(x_i) g_i(y) ; f_i \in C^0_0(S), g_i \in \mathcal{D}_t, N \in N \}$ denote the algebraic tensor product of $C^0_0(S)$ and $\mathcal{D}_t$.

**Definition 2.1.** A $\mathbb{R}^d$-valued function $d^\mu \in L^1_{\text{loc}}(\mu)$ is called the logarithmic derivative of $\mu$ if, for all $\varphi \in C^0_0(S) \otimes \mathcal{D}_t$,

$$\int_{S \times S} d^\mu(x, y) \varphi(x, y) \mu^{[1]}(dxdy) = - \int_{S \times S} \nabla_x \varphi(x, y) \mu^{[1]}(dxdy).$$

**Remark 2.3.** (1) The logarithmic derivative $d^\mu$ is determined uniquely (if exists).
(2) If the boundary $\partial S$ is nonempty and particles hit the boundary, then $d^\mu$ would contain a term arising from the boundary condition. For example, if the Neumann boundary condition is imposed on the boundary, then there would be local time-type drifts. We shall later assume that particles never hit the boundary, and the above formulation is thus sufficient in the present situation.
(3) A sufficient condition for the explicit expression of the logarithmic derivative of point processes is given in [13, Theorem 45]. Using this, one can obtain the logarithmic derivative of point processes appearing in random matrix theory such as sine, Airy, Ginibre point process (see Examples in Section 5). For canonical Gibbs measures with Ruelle-class interaction potentials, one can easily calculate the logarithmic derivative employing DLR equation [25, Lemma 10.10].

We assume:

- (J1) Each $\mu^N$ has a logarithmic derivative $d^N$, and the coefficient $b^N$ is given as

$$b^N = \frac{1}{2} \{ \nabla_x a^N + a^N d^N \}.$$  

Furthermore, the vector-valued functions $\{\nabla_x a^N\}_N$ are continuous and converge to $\nabla_x a$ uniformly on each $S_t \times S$, where $\nabla_x a^N$ is the $d$-dimensional column vector such that

$$\nabla_x a^N(x, y) = (\sum_{i=1}^d \frac{\partial}{\partial x_i} a_{1i}^N(x, y), \ldots, \sum_{i=1}^d \frac{\partial}{\partial x_i} a_{di}^N(x, y)).$$

**Remark 2.4.** From (J1) we see that the delabeled dynamics $X^N = \sum_{i=1}^N \delta_{X_i^N}$ of $X^N$ is reversible with respect to $\mu^N$. Thus (J1) relates the measure $\mu^N$ with the labeled dynamics $X^N$. For each $N < \infty$, $X^N$ has a reversible measure. Indeed, the symmetrization $(\mu^N \circ \ell^{-1})_{\text{sym}}$ of $\mu^N \circ \ell^{-1}$ is a reversible measure of $X^N$ as we see for $\mu^N$ in Introduction, where $(\mu^N \circ \ell^{-1})_{\text{sym}} = \frac{1}{N!} \sum_{\sigma \in \mathfrak{S}_N} (\mu^N \circ \ell^{-1})_{\sigma \sigma^{-1}}$ and $\mathfrak{S}_N$ is the symmetric group of order $N$. When $N = \infty$, $X$ does not have any reversible measure in general. For example, infinite-dimensional Brownian motion $B = (B^i)_{i \in N}$ on $(\mathbb{R}^d)^N$ has no reversible measures. We also remark that the Airy$_{ij}$ $(\beta = 1, 2, 4)$ interacting Brownian motion defined by [11] has a reversible measure given by $\mu_{\text{Airy}, \beta} \circ \ell^{-1}$ with label $\ell(s) = (s_1, s_2, \ldots)$ such that $s_i > s_{i+1}$ for all $i \in N$ because $\ell$ gives a bijection from (a subset of) $S$ to $\mathbb{R}^N$ defined for $\mu_{\text{Airy}, \beta}$-a.s. $s$, and thus the relation $X_t = \ell(X_t)$ holds for all $t$.

We prove that convergence of the logarithmic derivative implies weak convergence of the solutions of the associated SDEs. Each logarithmic derivative $d^N$ belongs to a different $L^p$-space $L^p(\mu^{[1]}_N)$, and $\mu^{[1]}_N$ are mutually singular. Hence we decompose $d^N$ to define a kind of $L^p$-convergence.
Let $u, u^N, w : S \to \mathbb{R}^d$ and $g, g^N, v, v^N : S^2 \to \mathbb{R}^d$ be measurable functions. We set

\begin{align}
(2.34) & \quad \mathcal{g}_s(x,y) = \int_S \chi_s(x-y)v(x,y)dy + \sum_i \chi_s(x-y_i)g(x,y_i), \\
(2.35) & \quad g^N_s(x,y) = \int_S \chi_s(x-y)v^N(x,y)dy + \sum_i \chi_s(x-y_i)g^N(x,y_i), \\
(2.36) & \quad w^N_s(x,y) = \int_S \{1 - \chi_s(x-y)\}v^N(x,y)dy + \sum_i (1 - \chi_s(x-y_i))g^N(x,y_i),
\end{align}

where $y = \sum_i \delta_{y_i}$ and $\chi_s \in C_0^\infty(S)$ is a cut-off function such that $0 \leq \chi_s \leq 1$, $\chi_s(x) = 0$ for $|x| > s + 1$, and $\chi_s(x) = 1$ for $|x| \leq s$. We assume the following.

**J2** Each $\mu^N$ has a logarithmic derivative $d^N$ such that

\begin{equation}
(2.37) \quad d^N(x,y) = u^N(x) + g^N_s(x,y) + w^N_s(x,y).
\end{equation}

Furthermore, we assume that

1. $u^N$ are in $C^1(S)$. Furthermore, $u^N$ and $\nabla u^N$ converge uniformly to $u$ and $\nabla u$, respectively, on each compact set in $S$.
2. For each $s \in \mathbb{N}$, $\int_S \chi_s(x-y)v^N(x,y)dy$ are in $C^1(S)$. Furthermore, functions $\int_S \chi_s(x-y)v^N(x,y)dy$ and $\nabla_x \int_S \chi_s(x-y)v^N(x,y)dy$ converge uniformly to $\int_S \chi_s(x-y)v(x,y)dy$ and $\nabla_x \int_S \chi_s(x-y)v(x,y)dy$, respectively, on each compact set in $S$.
3. $g^N$ are in $C^1(S^2 \setminus \{x \neq y\})$. Furthermore, $g^N$ and $\nabla_x g^N$ converge uniformly to $g$ and $\nabla_x g$, respectively, on $S^2 \setminus \{|x-y| \geq 2^{-p}\}$ for each $p > 0$. In addition, for each $r \in \mathbb{N}$,

\begin{equation}
(2.36) \quad \lim_{N \to \infty} \lim_{s \to \infty} \int_{x \in S_r,|x-y| \leq 2^{-s}} \chi_s(x-y)|g^N(x,y)|^p \rho_{x^N,1}(y)dx dy = 0,
\end{equation}

where $\rho_{x^N,1}$ is a one-correlation function of the reduced Palm measure $\mu^N_r$.
4. There exists a continuous function $w : S \to \mathbb{R}$ such that

\begin{equation}
(2.37) \quad \lim_{s \to \infty} \lim_{N \to \infty} \int_{S_r \times S} |w^N_s(x,y) - w(x)|^p d\rho_{x^N,1} = 0, \quad w \in L_p^{loc}(S,dx).
\end{equation}

Let $p$ be such that $1 < p < \hat{p}$. Assume **H1** and **J2**. Then from [19] Theorem 45 we see that the logarithmic derivative $d^\mu$ of $\mu$ exists in $L_p^{loc}(\mu[1])$ and is given by

\begin{equation}
(2.38) \quad d^\mu(x,y) = u(x) + g(x,y) + w(x).
\end{equation}

Here $g(x,y) = \lim_{s \to \infty} \mathcal{g}_s(x,y)$ and the convergence of $\lim \mathcal{g}_s$ takes place in $L_p^{loc}(\mu[1])$. We now introduce the ISDE of $X = (X^i)_{i \in \mathbb{N}}$:

\begin{align}
(2.39) & \quad dX^i_t = \sigma(X^i_t, X^{2i}_t)dB^i_t + \frac{1}{2} \{\nabla_x a(X^i_t, X^{2i}_t) + a(X^i_t, X^{2i}_t)\} d\mu^N(X^i_t, X^{2i}_t) dt \\
(2.40) & \quad X^i_0 = s.
\end{align}

Here $\nabla_x a$ is defined similarly as (2.38). If $\sigma$ is the unit matrix and **J2** is satisfied, we have

\begin{equation}
(2.41) \quad dX^i_t = dB^i_t + \frac{1}{2} \{u(X^i_t) + w(X^i_t) + g(X^i_t, X^{2i}_t)\} dt.
\end{equation}

In the sequel, we give a sufficient condition for solving ISDE (2.39) (and (2.41)).

Let $D$ be the standard square field on $S$ such that for any $f, g \in D_0$ and $s = \sum_i \delta s_i$, $D[f, g](s) = \frac{1}{2} \{ \sum_i \nabla_i f \cdot \nabla_i g \}(s)$,
We assume: the closure (using a general theory of quasi-regular Dirichlet forms, we deduce the existence of the associated S-valued diffusion \((P, X)\) \([14]\). By construction, \((P, X)\) is \(\mu\)-reversible.

Let \(\text{Erf}(t) = \frac{2}{\sqrt{\pi}} \int_0^t e^{-x^2} dx\) be the error function. Let \(S_r = \{|x| < r\}\) as before. We assume:

\[[\text{J4}]\] \(\text{Cap}^\mu(\{S_{s_i}\}) = 0\).

Let \(\text{Erf}(t) = \frac{2}{\sqrt{\pi}} \int_0^t e^{-x^2} dx\) be the error function. Let \(S_r = \{|x| < r\}\) as before. We assume:

\[[\text{J5}]\] There exists a \(Q > 0\) such that for each \(R > 0\)

\[
(2.42) \quad \lim_{r \to \infty} \sup_{N \in \mathbb{N}} \left\{ \int_{S_{r+R}} \rho^{N,1}(x) dx \right\} \text{Erf} \left( \frac{r}{\sqrt{(r+R)Q}} \right) = 0.
\]

We write \(s_i = \ell_N(s_i)\) and assume for each \(r \in \mathbb{N}\)

\[
(2.43) \quad \lim_{L \to \infty} \limsup_{N \to \infty} \sum_{i \geq L} \int_{S_i} \text{Erf} \left( \frac{|s_i| - r}{\sqrt{Q}} \right) \mu^N(ds_i) = 0.
\]

We remark that \((2.43)\) is easy to check. Indeed, we prove in Lemma 4.6 that, if \(s_i = \ell_N(s_i)\) is taken such that

\[
(2.44) \quad |s_1| \leq |s_2| \leq \cdots,
\]

then \((2.43)\) follows from \((\text{H1})\) and \((\text{J4})\) below.

\[
(2.45) \quad \lim_{q \to \infty} \limsup_{N \to \infty} \int_{S_{q,N}} \text{Erf} \left( \frac{|x| - r}{\sqrt{Q}} \right) \rho^{N,1}(x)dx = 0.
\]

Let \(\ell\) be the label as before. Let \(X = (X^i)_{i \in \mathbb{N}}\) be a family of solution of \((2.39)\) satisfying \(X_0 = s\) for \(\mu \circ \ell^{-1}\) a.s. \(s\). We call \(X\) satisfies \(\mu\)-absolute continuity condition if

\[
(2.46) \quad \mu_t \prec \mu \quad \text{for all } t \geq 0,
\]

where \(\mu_t\) is the distribution of \(X_t\) and \(\mu_t \prec \mu\) means \(\mu_t\) is absolutely continuous with respect to \(\mu\).

Here \(X_t = \sum_{i \in \mathbb{N}} \delta_{X_t^i}\), for \(X_t = (X^i_t)_{i \in \mathbb{N}}\). By definition \(X = \{X_t\}_t\) is the delabeled dynamics of \(X\) and by construction \(X_0 = \mu\) in distribution.

We say ISDE \((2.39)\) has \(\mu\)-uniqueness of solutions in law if \(X\) and \(X'\) are solutions with the same initial distributions satisfying the \(\mu\)-absolute continuity condition, then they are equivalent in law. We assume:

\[[\text{J6}]\] ISDE \((2.39)\) has \(\mu\)-uniqueness of solutions in law.
Let $X^N$ be a solution of \((2.4)\). From \((2.32)\) we can rewrite \((2.4)\) as

\begin{equation}
(2.47) \quad dX^N_{t,i} = \sigma^N(X^N_{t,i}, X^N_{t,\sigma(i)})dB^i_t + \frac{1}{2} \{\nabla_x a^N + a^N \partial X^N_{t,i}, X^N_{t,\sigma(i)}\}dt.
\end{equation}

We set $X^{N,m} = (X^{N,1}, X^{N,2}, \ldots, X^{N,m})$ for $1 \leq m \leq N$ and $X^m = (X^1, X^2, \ldots, X^m)$. We say $\{X^N\}$ is tight in $C([0,\infty); S^N)$ if each subsequence $\{X^{N'}\}$ contains a subsequence $\{X^{N''}\}$ such that $\{X^{N'',m}\}$ is convergent weakly in $C([0,\infty); S^m)$ for each $m \in \mathbb{N}$.

**Theorem 2.2.** Assume (H1)–(H4) and (J1)–(J5). Assume that $X^N_0 = \mu^N \circ \ell_0^{-1}$ in distribution. Then $\{X^N\}$ is tight in $C([0,\infty); S^N)$ and each limit point $X$ of $\{X^N\}$ is a solution of \((2.39)\) with initial distribution $\mu \circ \ell^{-1}$. Furthermore, if we assume (J6) in addition, then for any $m \in \mathbb{N}$

\begin{equation}
(2.48) \quad \lim_{N \to \infty} X^{N,m} = X^m \text{ weakly in } C([0,\infty), S^m).
\end{equation}

**Remark 2.5.** To prove \((2.48)\) it is sufficient to prove the convergence in $C([0,T];S^m)$ for each $T \in \mathbb{N}$. We do this in the following sections.

**Remark 2.6.** (1) A sufficient condition for (J3) is obtained in [20, 21]. Indeed, if $\mu$ is a $(\Phi, \Psi)$-quasi-Gibbs measure with upper semi-continuous potential $(\Phi, \Psi)$, then (J3) is satisfied. This condition is mild and is satisfied by all examples in the present paper. We refer to [20, 21] for the definition of quasi-Gibbs property.

(2) From the general theory of Dirichlet forms, we see that (J4) is equivalent to the non-collision of particles [4]. We refer to [16] for a necessary and sufficient condition of this non-collision property of interacting Brownian motions in finite-dimensions, which gives a sufficient condition of non-collision in infinite dimensions. We also refer to [17] for a sufficient condition for non-collision property of interacting Brownian motions in infinite-dimensions applicable to, in particular, determinantal point processes.

(3) From \((2.32)\) of (J5), we deduce that each tagged particle $X^i$ does not explode [4, 13]. We remark that the delabeled dynamics $X = \sum_1^\infty \delta_X^i$ are $\mu$-reversible, and they thus never explode. Indeed, as for configuration-valued diffusions, explosion occurs if and only if infinitely many particles gather in a compact domain, so the explosion of tagged particle does not imply that of the configuration-valued process.

(4) It is known that, if we suppose (H1), (J1)–(J5), then ISDE \((2.39)\) has a solution for $\mu \circ \ell^{-1}$-a.s. satisfying the non-collision and non-explosion property [19]. Indeed, let $X = (X^i)$ be the $S^N$-valued continuous process consisting of tagged particles $X^i$ of the delabeled diffusion process $X = \sum_{i \in \mathbb{N}} \delta_X^i$, given by the Dirichlet form of (J3). Then from (J4) and (J5) \((2.42)\) we see $X$ is uniquely determined by its initial starting point. It was proved that $X$ is a solution of \((2.39)\) in [19].

**Remark 2.7.** Assumption (J6) follows from tail triviality of $\mu$ [25], where tail triviality of $\mu$ means that the tail $\sigma$-field $\mathcal{T} = \bigcap_{n>0} \sigma[\mathbb{P}^n]$ is $\mu$-trivial. Indeed, from tail triviality of $\mu$ and marginal assumptions ((E1), (F1), and (F2) in [25]), we obtain (J6). Tail triviality holds for all determinantal point processes [22] and grand canonical Gibbs measures with sufficiently small inverse temperature $\beta > 0$.

3. **Proof of Theorem 2.1**

The purpose of this section is to prove Theorem 2.1. We assume the same assumptions as Theorem 2.1 throughout this section. We begin by proving \((2.20)\).

**Lemma 3.1.** \((2.20)\) holds.

**Proof.** From (H1) and \((2.20)\), we obtain

\begin{equation}
(3.1) \quad \lim_{N \to \infty} b^N_{r,s,p} = b_{r,s,p} \text{ for } \mu^i[1]-\text{a.s. and in } L^p(\bar{\mu}^i[1]).
\end{equation}
We next prove the convergence of \( \{b_{r,s,p}\} \) as \( p \to \infty \). Note that
\[
\|b_{r,s,p} - b_{r,s,q}\|_{L^p(\bar{\mu}_t^{[1]})} \\
\leq \|b_{r,s,p} - b_{r,s,p}^N\|_{L^p(\bar{\mu}_t^{[1]})} + \|b_{r,s,p}^N - b_{r,s,q}\|_{L^p(\bar{\mu}_t^{[1]})} + \|b_{r,s,q} - b_{r,s,q}\|_{L^p(\bar{\mu}_t^{[1]})}.
\]
From (2.22) for each \( \epsilon \) there exists a \( p_0 \) such that for all \( p, q \geq p_0 \)
\[
\sup_{N \in \mathbb{N}} \|b_{r,s,p}^N - b_{r,s,q}\|_{L^p(\bar{\mu}_t^{[1]})} < \epsilon
\]
By (3.1), there exists an \( N = N_{p,q} \) such that
\[
\|b_{r,s,p} - b_{r,s,q}\|_{L^p(\bar{\mu}_t^{[1]})} < \epsilon, \quad \|b_{r,s,q} - b_{r,s,q}\|_{L^p(\bar{\mu}_t^{[1]})} < \epsilon.
\]
Putting (3.3) and (3.4) into (3.2), we deduce that \( \{b_{r,s,p}\}_{p \in \mathbb{N}} \) is a Cauchy sequence in \( L^p(\bar{\mu}_t^{[1]}) \).

Hence from (2.10), (2.22), and (2.25) we see
\[
\text{lim}_{p \to \infty} b_{r,s,p} = b_{r,s} \quad \text{in} \quad L^p(\bar{\mu}_t^{[1]}).
\]
Recall that \( b_{r,s} = E\bar{\mu}_t^{[1]}[b^N_r|\mathcal{F}_{r,s}] \) by (2.10). Then, because \( \mathcal{F}_{r,s} \subset \mathcal{F}_{r,s+1} \), we have
\[
E\bar{\mu}_t^{[1]}[b^N_r|\mathcal{F}_{r,s}] = E\bar{\mu}_t^{[1]}[b^N_{r,s+1}|\mathcal{F}_{r,s}] = E\bar{\mu}_t^{[1]}[b_{r,s+1}|\mathcal{F}_{r,s}].
\]
From this and (2.17) we obtain
\[
\sup_{r < s} \limsup_{N \to \infty} \|b^N_{r,s}\|_{L^p(\bar{\mu}_t^{[1]})} \leq \limsup_{N \to \infty} \|b^N_r\|_{L^p(\bar{\mu}_t^{[1]})} < \infty.
\]
Combining (2.25), (3.6), and (3.7), we have
\[
b_{r,s} = \lim_{N \to \infty} b^N_{r,s} = \lim_{N \to \infty} E\bar{\mu}_t^{[1]}[b^N_{r,s+1}|\mathcal{F}_{r,s}] = E\bar{\mu}_t^{[1]}[b_{r,s+1}|\mathcal{F}_{r,s}].
\]
From (H1), (2.25), (3.6), and Fatou’s lemma, we see that
\[
\sup_{r < s} \|b_{r,s}\|_{L^p(\bar{\mu}_t^{[1]})} \leq \sup_{r < s} \liminf_{N \to \infty} \|b^N_{r,s}\|_{L^p(\bar{\mu}_t^{[1]})} < \infty.
\]
From (3.8) we deduce that \( \{b_{r,s}\}_{s+r+1} \) is martingale in \( s \). Applying the martingale convergence theorem to \( \{b_{r,s}\}_{s+r+1} \) and using (3.9), we deduce that there exists a \( b_r \) such that
\[
b_{r,s} = E\bar{\mu}_t^{[1]}[b_{r}|\mathcal{F}_{r,s}]
\]
and that
\[
\lim_{s \to \infty} b_{r,s} = b_r \quad \text{for} \quad \bar{\mu}_t^{[1]}-\text{a.s.} \quad \text{and in} \quad L^p(\bar{\mu}_t^{[1]}).
\]
By the consistency of \( \{\bar{\mu}_t^{[1]}\}_{t \geq 0} \) in \( r \), the function \( b_r \) in (3.10) can be taken to be independent of \( r \). This together with (3.10) completes the proof of (2.25). \( \square \)

We proceed with the proof of the latter half of Theorem 2.1. Recall SDE (2.4). Then
\[
X_t^{N,i} - X_0^{N,i} = \int_0^t \sigma^N(X_u^{N,i}, X_u^{N,\bar{\mu}})dB_u^i + \int_0^t b^N(X_u^{N,i}, X_u^{N,\bar{\mu}})du.
\]
Using the decomposition in (2.28), we see from (3.11) that
\[
X_t^{N,i} - X_0^{N,i} = \int_0^t \sigma^N(X_u^{N,i}, X_u^{N,\bar{\mu}})dB_u^i + \int_0^t \{b_{r,s,p}^N + b_{r,s,p}^{\text{tail}}\}(X_u^{N,i}, X_u^{N,\bar{\mu}})du
\]
\[
+ \int_0^t \left( \{b_{r,s} - b_{r,s,p}^N\} + b_{r,s}^{\text{tail}} - b_{r,s}^{\text{tail}} \right)(X_u^{N,i}, X_u^{N,\bar{\mu}})du.
\]
Let \( \partial_{i,j} = \frac{\partial}{\partial x_i x_j}, \) \( x_i = (x_i)_d, \) \( x_m = (x_i)_m \in (\mathbb{R}^d)^m. \) Set \( \nabla_i = (\partial_{i,j})_{j=1}^d. \) Let 
\[ \psi \in C^{\infty}_{\partial}(S^m) \] and 
\[ a_i^N \partial_{i,j} \psi(x_m) = \sum_{k,l=1}^d a_{k,l}^N(x_i) \partial_{k,l} \psi(x_m). \] Applying the Itô formula to \( \psi \) and \( \text{(3.12)}, \) and putting \( X_t^{N,m} = (X^N_{t,1}, \ldots, X^N_{t,m}), \) we deduce that
\[
(3.13) \quad \psi(X_t^{N,m}) - \psi(x_m^{N,m}) = \sum_{i=1}^m \left( \int_0^t \nabla_i \psi(X_u^{N,m}) \cdot \sigma^N(X_u^{N,i}, X_u^{N,oi}) dB_u^i \right.
\[
+ \int_0^t \frac{1}{2} a_i^N \partial_{i,j} \psi(X_u^{N,m}) + \{b_{r,s,p}^N + b_{\text{tail}}^N\}(X_u^{N,i}, X_u^{N,oi}) \cdot \nabla_i \psi(X_u^{N,m}) du
\[
+ \sum_{i=1}^m \int_0^t \nabla_i \psi(X_u^{N,m}) \cdot \{b_{r,s}^N - b_{r,s,p}^N\}(X_u^{N,i}, X_u^{N,oi}) du
\[
+ \left. \sum_{i=1}^m \int_0^t \nabla_i \psi(X_u^{N,m}) \cdot \{b_{r,s}^N - b_{\text{tail}}^N\}(X_u^{N,i}, X_u^{N,oi}) du. \right)
\]
We set
\[
Q_{r,s,p}^N = \sum_{i=1}^m \int_0^T \left\{ b_{r,s}^N - b_{r,s,p}^N \right\}(X_u^{N,i}, X_u^{N,oi}) du,
\]
\[
R_{r,s}^N = \sum_{i=1}^m \int_0^T \left\{ b_{r,s}^N - b_{\text{tail}}^N \right\}(X_u^{N,i}, X_u^{N,oi}) du.
\]

**Lemma 3.2.** For each \( m, r < s \in \mathbb{N} \)
\[
\lim_{p \to \infty} \limsup_{N \to \infty} \mathbb{E}^{\mu^{N} \sigma^{-N}} \left[ Q_{r,s,p}^N \right] = 0, \quad \lim_{s \to \infty} \limsup_{N \to \infty} \mathbb{E}^{\mu^{N} \sigma^{-N}} \left[ R_{r,s}^N \right] = 0.
\]

**Proof.** Lemma 3.2 follows from \( \text{(2.23)} \) and \( \text{(2.27)} \) immediately. \( \square \)

Let \( \Xi = S^m \times (\mathbb{R}^d)^m \times (\mathbb{R}^d)^m \) and \( \psi \in C^{1,2}_{\partial}(S^m). \) Let \( F : C([0,T]; \Xi) \to C([0,T]; \mathbb{R}) \) such that
\[
F(\xi, \eta, \zeta)(t) = \psi(\xi(t)) - \psi(\xi(0)) - \int_0^t \sum_{i=1}^m \zeta_i(u) \cdot \nabla_i \psi(\xi(u)) du
\]
\[
- \int_0^t \sum_{i=1}^m \left( \frac{1}{2} b_{i}(u) \Delta \psi(\xi(u)) + b_{\text{tail}}(\xi(u)) \cdot \nabla_i \psi(\xi(u)) \right) du,
\]
where \( \xi = (\xi^i_{m=1})^m, \eta = (\eta^i_{m=1})^m, \delta = (\delta^i_{m=1})^m, \zeta = (\zeta^i_{m=1})^m, \) and \( \Delta_i = \sum_{j=1}^d \partial_{i,j}^2. \)

As \( \psi \in C^{1,2}_{\partial}(S^m) \) and \( b_{\text{tail}} \in C(S^m) \) by definition, we see that \( F \) satisfies the following.

(1) \( F \) is continuous.
(2) \( F(\xi, \eta, \zeta) \) is bounded in \( (\xi, \eta) \) for each \( \zeta, \) and linear in \( \zeta \) for each \( (\xi, \eta). \)

Let \( A^{N,m} = (A^N_{i,j,l})_{i,j,l=1}^m \) and \( B_{r,s,p}^{N,m} = (B_{r,s,p}^N)_{i=1}^m \) such that
\[
A_{r,s}^N(t) = a^N(X_t^{N,i}, X_t^{N,oi}), \quad B_{r,s,p}(t) = b_{r,s,p}^N(X_t^{N,i}, X_t^{N,oi}).
\]
Then we see from \( \text{(3.13)} - \text{(3.15)} \) that for each \( m \in \mathbb{N} \)
\[
(3.16) \quad \left| \int F(X_t^{N,m}, A_t^{N,m}, B_{r,s,p}^{N,m}) - \sum_{i=1}^m \int_0^t \nabla_i \psi(X_u^{N,m}) \cdot \sigma^N(X_u^{N,i}, X_u^{N,oi}) dB_u^i \right|
\]
\[
\leq c_7 \left( Q_{r,s,p}^N + R_{r,s}^N \right),
\]
where \( c_7 = \mathbb{E}^{\psi} \) is the constant such that \( c_7 = \max_{i=1}^m \| \nabla_i \psi \|_{\mathbb{R}^m} = (\| \cdot \| A \) is the uniform norm over \( A \) as before). We take the limit of each term in \( \text{(3.16)} \) in the sequel.

**Lemma 3.3.** \( \{X^N_i\}_{N \in \mathbb{N}}, \{A^N_{i,j}\}_{N \in \mathbb{N}} \) and \( \{B_{r,s,p}^N\}_{N \in \mathbb{N}} \) are tight for each \( i, r, s, p \in \mathbb{N}. \)
Proof. The tightness of \( \{X^{N,i}_t\}_{N \in \mathbb{N}} \) is clear from (I1).

We note that \( \{\nabla_i a_N^i\}_N \) is uniformly bounded on \( S_r \times S \) for each \( r \in \mathbb{N} \) by (H4). Hence from this and (I1) there exists a constant \( c_0 \) independent of \( N \) such that for all \( 0 \leq u, v \leq T \)
\[
E^{N,0}_{t,c^{N,i}t} |A^{N,i}(u) - A^{N,i}(v)|^2; \sup_{t \in [0,T]} |X^{N,i}_t| \leq a \leq c_0 |u - v|^2.
\]

By (I1) we see that \( \{A^{N,i}(0)\}_{N \in \mathbb{N}} \) is tight. Combining these deduces the tightness of \( \{A^{N,i}\}_{N \in \mathbb{N}} \).

Recall that \( B^{N,i}_{r,s,p}(t) = b^{N,i}_{r,s,p}(X^{N,i}_t, X^{N,i}_t) \) and that \( b^{N,i}_{r,s,p} \) is \( F_{r,s} \)-measurable by assumption. By construction
\[
P^{N,0}_{t,c^{N,i}t} (X^{N,j}_t \in S_r \text{ for all } 1 \leq j \leq m, 0 \leq t \leq T \mid \mathcal{L}^N_{r+s} \leq m) = 1.
\]

Let \( c_9 = \sup_{N \in \mathbb{N}} \|b^{N,i}_{r,s,p}(\cdot)\|_{S_r} \). From (3.15), (2.21), (3.17), and (2.8) we see
\[
E^{N,0}_{t,c^{N,i}t} |B^{N,i}_{r,s,p}(u) - B^{N,i}_{r,s,p}(v)|^2; \sup_{t \in [0,T]} |X^{N,i}_t| \leq a \leq c_9 |u - v|^2
\]
\[
= E^{N,0}_{t,c^{N,i}t} |b^{N,i}_{r,s,p}(X^{N,i}_u, X^{N,i}_v) - b^{N,i}_{r,s,p}(X^{N,i}_u, X^{N,i}_v)|^2; \sup_{t \in [0,T]} |X^{N,i}_t| \leq a \leq \mathcal{L}^N_{r+s} \leq m
\]
\[
\leq E^{N,0}_{t,c^{N,i}t} \sum_{r,s,m=1}^m |X^{N,i}_r - X^{N,i}_s|^2; \sup_{t \in [0,T]} |X^{N,i}_t| \leq a \leq \mathcal{L}^N_{r+s} \leq m
\]
\[
\leq c_9 \sum_{r,s,m=1}^m |u - v|^2 \text{ for all } 0 \leq u, v \leq T.
\]

From this, (2.7), and (2.9), we deduce the tightness of \( \{B^{N,i}_{r,s,p}\}_{N \in \mathbb{N}} \). \( \square \)

Lemma 3.4. \( \{(X^{N,i}, A^{N,i}, B^{N,i}_{r,s,p})_{i=1}^m\}_{N \in \mathbb{N}} \) is tight in \( C([0,T], \mathbb{R}^m) \) for each \( m, r, s, p \in \mathbb{N} \).

Proof. Lemma 3.4 is obvious from Lemma 3.3. Indeed, the tightness of the probability measures on a countable product space follows from that of the distribution of each component. \( \square \)

Assumption (I1) and Lemma 3.3 combined with the diagonal argument imply that for any subsequence of \( \{(X^{N,i}, A^{N,i}, B^{N,i}_{r,s,p})_{i=1}^m\}_{N \in \mathbb{N}, r<s<\infty} \), there exists a convergent-in-law subsequence, denoted by the same symbol. That is, for each \( p, s, r, m \in \mathbb{N} \),
\[
\lim_{N \to \infty} (X^{N,i}, A^{N,i}, B^{N,i}_{r,s,p})_{i=1}^m = (X^i, A^i, B^i_{r,s,p})_{i=1}^m \text{ in law}.
\]

We thus assume (3.18) in the rest of this section.

Let \( A^m = (A^i)_{i=1}^m \), \( B^{N,m}_{r,s,p} = (B^{N,i}_{r,s,p})_{i=1}^m \), and \( X^m = (X^i)_{i=1}^m \) for \( X = (X^i)_{i \in \mathbb{N}} \) in Theorem 2.1.

Lemma 3.5. For each \( m \in \mathbb{N} \)
\[
\lim_{N \to \infty} F(X^{N,m}, A^{N,m}, B^{N,m}_{r,s,p}) = F(X^m, A^m, B^m_{r,s,p}) \text{ in law}.
\]

Moreover, \( A^i \) and \( B^{r,s,p}_i \) are given by
\[
A^i(t) = a(X^i_t, X^{o,i}_t), \quad B^i_{r,s,p}(t) = b_{r,s,p}(X^i_t, X^{o,i}_t).
\]

Proof. Recall that \( F(\xi, \eta, \zeta) \) is continuous. Hence (3.19) follows from (5.13). By (H4) we see \( \{a^N\} \) converges to \( a \) uniformly on each \( S_r \times S \). Then, from this, (2.20), and (3.15) we obtain (5.20). \( \square \)

Lemma 3.6. For each \( m \in \mathbb{N} \)
\[
\lim_{N \to \infty} \sum_{i=1}^m \int_0^T \nabla_i \psi(X^{N,m}_u) \cdot \sigma^N(X^{N,i}_u, X^{o,i}_u)dB^{r,s}_u = \sum_{i=1}^m \int_0^T \nabla_i \psi(X^m_u) \cdot \sigma(X^i_u, X^{o,i}_u)dB^{i}_{r,s,p} \text{ in law},
\]
where \( (B^{i}_{r,s,p})_{i=1}^m \) is the first \( m \)-components of a \( (\mathbb{R}^d)^N \)-valued Brownian motion \( (B^i)_{i \in \mathbb{N}} \).
From (H4), we see that $a^N$ converges to $a$ uniformly on $S_r$ for each $r \in \mathbb{N}$. Hence we deduce from (11) and $\psi \in C_0^\infty(S^m)$ the convergence in law such that

$$\lim_{N \to \infty} \sum_{i=1}^m \int_0^t \sigma^N_{\partial_i}(X^{N,i}_u, X^{N,\omega}_u) \, d\hat{B}^i_u \quad \text{in } \mathbb{R}^m.$$  

Here, $\psi$ is the quadratic variation of $\sum_{i=1}^m \int_0^t \nabla_i \psi(X^{m}_u) \cdot \sigma(X^{i}_u, X^{\omega}_u) \, d\hat{B}^i_u$. This completes the proof.

We are now ready for the proof of Theorem 2.1.

**Proof of Theorem 2.1.** From Lemma 3.2 and 3.10, we deduce that

$$\limsup_{N \to \infty} E^{\nu} \left[ \sup_{0 \leq t \leq T} \left| F(X^{N,m}, A^{N,m}, B_{r,s,p}^{N,m})(t) \right| \right] \leq \left( 10 \right) s, p, \psi,$$

where $0 \leq c_{10}(s, p) = \left( 10 \right) s, p, \psi \leq \infty$ is a constant depending on $s, p, \psi$. Applying Lemma 3.5 and Lemma 3.6 to 3.10, we then deduce that

$$E^{\nu} \left[ \sup_{0 \leq t \leq T} \left| F(X^m, A^m, B_{r,s,p}^m)(t) - \sum_{i=1}^m \int_0^t \nabla_i \psi(X^m_u) \cdot \sigma(X^i_u, X^{\omega}_u) \, d\hat{B}^i_u \right| \right] \leq \left( 10 \right) s, p.$$  

From this and (3.21), we obtain that

$$(3.21) \quad E^{\nu} \left[ \sup_{0 \leq t \leq T} \left| \psi(X^m_t) - \psi(X^0_m) - \sum_{i=1}^m \int_0^t \nabla_i \psi(X^m_u) \cdot \sigma(X^i_u, X^{\omega}_u) \, d\hat{B}^i_u \right| \right] \leq \left( 10 \right) s, p.$$  

Take $\psi = \psi \in C_0(S^m)$ such that $\psi(x_1, \ldots, x_m) = x_i$ for $|x_j| \leq R; j = 1, \ldots, m$ while keeping $|\nabla \psi|$ bounded in such a way that

$$\left( 10 \right) (p, s) = \sup_{R} \left( 10 \right) (p, s, R) = o(p, s).$$
Lemma 4.1.\hspace{1em} (4.2)\hspace{1em} (I1)

in Theorem 2.2 and Theorem 2.1. Hence our task is to derive condition (J2)

from conditions (4.1), (4.2), (2.35), and (2.37) correspond to (4.15), (4.30), (4.29), and (4.31) in [19]. Then all

the assumptions of [19] Theorem 45 are satisfied. We thus deduce Lemma 4.1 from [19, Theorem 45].

Proof. We use a general theory developed in [19]. \hspace{1em} (H1)\hspace{1em} (H4) are commonly assumed in
Theorem 2.2 and Theorem 2.1. Hence our task is to derive condition (J1)–(J5) from conditions stated in Theorem 2.2. From (J2) we easily deduce that

\begin{align}
\lim_{N \to \infty} u^N &= u \quad \text{in } L^\frac{p}{p}((S, dx), \hspace{1em} (4.1) \\
\lim_{N \to \infty} g^N &= g_s \quad \text{in } L^p((\mu[1]), \hspace{1em} (4.2)}
\end{align}

Lemma 4.1. \mu has a logarithmic derivative d\mu \in L^p_{loc}(\mu[1]), where 1 \leq p < \hat{p}.

Proof. We use a general theory developed in [19]. (H1) corresponds to (4.1) and (4.2) in [19],\hspace{1em} (4.1), (4.2), (2.35), and (2.37) correspond to (4.15), (4.30), (4.29), and (4.31) in [19]. Then all

the assumptions of [19] Theorem 45 are satisfied. We thus deduce Lemma 4.1 from [19] Theorem 45.

4. PROOF OF THEOREM 2.2

Is this section we prove Theorem 2.2 using Theorem 2.1. (H1)–(H4) are commonly assumed in
Theorem 2.2 and Theorem 2.1. Hence our task is to derive condition (11)–(15) from conditions stated in Theorem 2.2. From (J2) we easily deduce that

\begin{align}
\lim_{N \to \infty} u^N &= u \quad \text{in } L^\frac{p}{p}((S, dx), \hspace{1em} (4.1) \\
\lim_{N \to \infty} g^N &= g_s \quad \text{in } L^p((\mu[1]), \hspace{1em} (4.2)}
\end{align}

Lemma 4.1. \mu has a logarithmic derivative d\mu \in L^p_{loc}(\mu[1]), where 1 \leq p < \hat{p}.

Proof. We use a general theory developed in [19]. (H1) corresponds to (4.1) and (4.2) in [19],\hspace{1em} (4.1), (4.2), (2.35), and (2.37) correspond to (4.15), (4.30), (4.29), and (4.31) in [19]. Then all

the assumptions of [19] Theorem 45 are satisfied. We thus deduce Lemma 4.1 from [19] Theorem 45.

Let \{X^N\}_{N \in \mathbb{N}} be a sequence of solutions in (2.24) and (2.23). We set the m-labeling

\begin{align}
X^N,m = (X^N,1, \ldots, X^N,m, \sum_{j=1}^N \delta_{X^N,j}).
\end{align}
It is known \[15, 19\] that \(X^{N,[m]}\) is a diffusion process associated with the Dirichlet form \(\mathcal{E}^{\mu^{N,[m]}}\) on \(L^2(S^m \times S, \mu^{N,[m]})\) such that

\[
\mathcal{E}^{\mu^{N,[m]}}(f, g) = \int_{S^m \times S} \frac{1}{2} \sum_{i=1}^{m} \nabla_i f \cdot \nabla_i g + D[f, g]d\mu^{N,[m]},
\]

where the domain \(\mathcal{D}^{[m]}\) is taken as the closure of \(\mathcal{D}_0^{[m]} = C^\infty_0(S^m) \otimes \mathcal{D}_2\). Note that the coordinate function \(x_i = x_i \otimes 1\) is locally in \(\mathcal{D}^{[m]}\). From this we can regard \(\{X^{N,i}_t\}\) as a Dirichlet process of the \(m\)-labeled diffusion \(X^N\) associated with the Dirichlet space as above. In other words, we can write

\[
X^{N,i}_t - X^{N,i}_0 = f_i(X^{N}_t) - f_i(X^{N}_0) =: A_i^f,
\]

where \(f_i(x, s) = x_i \otimes 1, x_i \in \mathbb{R}^d,\) and \(x = (x_i)_{i=1}^m \in (\mathbb{R}^d)^m\). By the Fukushima decomposition of \(X^{N,i}_t\), there exist a unique continuous local martingale additive functional \(\mathcal{M}^{N,i} = \{\mathcal{M}^{N,i}_t\}\) and an additive functional of zero energy \(\mathcal{N}^{N,i} = \{\mathcal{N}^{N,i}_t\}\) such that

\[
X^{N,i}_t - X^{N,i}_0 = \mathcal{M}^{N,i}_t + \mathcal{N}^{N,i}_t.
\]

We refer to \[4, Chapter 5\] for the Fukushima decomposition. Because of \[24\], we then have

\[
\mathcal{M}^{N,i}_t = \int_0^t \sigma^N(X^{N,i}_u, X^{N,oi}_u)dB_u, \quad \mathcal{N}^{N,i}_t = \int_0^t \nu^N(X^{N,i}_u, X^{N,oi}_u)du.
\]

**Lemma 4.2.** Let \(r_T : C([0, T]; S) \to C([0, T]; S)\) be such that \(r_T(X)_t = X_{T-t}\). Suppose that \(X^{N,[m]}_t = \mu^{N,[m]}\) in law. Then

\[
X^{N,i}_t - X^{N,i}_0 = \frac{1}{2} \mathcal{M}^{N,i}_t + \frac{1}{2} (\mathcal{M}^N_{T-t}(r_T) - \mathcal{M}^N_T(r_T)) \quad \text{a.s.}
\]

**Proof.** Applying the Lyons-Zheng decomposition \[1, Theorem 5.7.1\] to additive functionals \(A^f_i\) for \(1 \leq i \leq m\), we obtain \[13\]. \(\square\)

**Lemma 4.3.** \((11)\) holds.

**Proof.** Although \(\mathcal{M}^{N,i}\) is a \(d\)-dimensional martingale by definition, we assume \(d = 1\) here and prove only this case for simplicity. The general case \(d \geq 1\) can be proved in a similar fashion. Let \(c_{10}\) be the constant in \[2, 6\]. From the standard calculation of martingales and \[16\], we obtain

\[
E^{\mu^{N,[i]}_0} \mathbb{P} \left[ |M^{N,i}_u - M^{N,i}_0|^4 \right] = E^{\mu^{N,[i]}_0} \mathbb{P} \left[ |B_{(M^{N,i})_u} - B_{(M^{N,i})_0}|^4 \right]
\]

\[
= 3E^{\mu^{N,[i]}_0} \mathbb{P} \left[ |(M^{N,i}_u - (M^{N,i}_0)|^2 \right] \leq 111 |u - v|^2,
\]

where \(c_{11} = 3c_{10}^2\) and \(\{B_t\}\) is a one-dimensional Brownian motion. Applying the same calculation to \(M^{N,i}_{T-t}(r_T) - M^{N,i}_T\), we have

\[
E^{\mu^{N,[i]}_0} \mathbb{P} \left| M^{N,i}_{T-t}(r_T) - M^{N,i}_T(r_T) \right|^4 \leq 111 (t - u)^2 \quad \text{for each } 0 \leq t, u \leq T.
\]

Combining \[1, 3\] and \[1, 4\] with the Lyons-Zheng decomposition \[1, 5\], we thus obtain

\[
E^{\mu^{N,[i]}_0} \mathbb{P} \left| X^{N,i}_t - X^{N,i}_0 \right|^4 \leq 211 (t - u)^2 \quad \text{for each } 0 \leq t, u \leq T.
\]

Taking a sum over \(i = 1, \ldots, m\) in \[1, 8\], we deduce \[2, 8\]. We next prove \[2, 7\]. From \[1, 3\] we have

\[
2|X^{N,i}_t - X^{N,i}_0| \leq |M^{N,i}_t| + |\mathcal{M}^N_{T-t}(r_T) - \mathcal{M}^N_T(r_T)| \quad \text{a.s.}
\]

\[
|\mathcal{M}^N_{T-t}(r_T) - \mathcal{M}^N_T(r_T)| \leq 111 (t - u)^2 \quad \text{for each } 0 \leq t, u \leq T.
\]
From this and a representation theorem of martingales, we obtain
\begin{equation}
\tag{4.9}
P^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} \left( \sup_{t \in [0, T]} |X_{t}^{N,i} - X_{0}^{N,i}| \geq a \right) \\
\leq P^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} \left( \sup_{t \in [0, T]} |M_{t}^{N,i} - M_{0}^{N,i}| \geq a \right) \\
= 2P^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} \left( \sup_{t \in [0, T]} |M_{t}^{N,i}| \geq a \right)
\end{equation}

A direct calculation shows
\begin{equation}
\tag{4.10}
P^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} \left( \sup_{t \in [0, T]} |B_{(M_{N},i)}| \geq a \right) \leq P^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} \left( \sup_{t \in [0, \sqrt{a/T}]} |B_{t}| \geq a \right) \leq \operatorname{Erf}(\frac{a}{\sqrt{T}})
\end{equation}

From (4.9), (4.10), and (H2), we obtain (2.7).

We proceed with the proof of (2.9). Similarly as (4.9) and (4.10), we deduce
\begin{equation}
\tag{4.11}
P^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} \left( \inf_{t \in [0, T]} |X_{t}^{N,i}| \leq r \right) \leq P^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} \left( \sup_{t \in [0, T]} |X_{t}^{N,i} - X_{0}^{N,i}| \geq |X_{0}^{N,i}| - r \right) \\
\leq 2P^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} \left( \sup_{t \in [0, T]} |M_{t}^{N,i}| \geq |X_{0}^{N,i}| - r \right) \\
\leq 2 \int_{S} \operatorname{Erf}(\frac{|s| - r}{\sqrt{T}}) d\mu^{N}(ds),
\end{equation}

where $s_{i} = \ell_{N}(s)$. We note that $X_{0}^{N,i} = s_{i}$ by construction. From (4.11) and (2.37), we deduce
\begin{align*}
\lim_{N \to \infty} \sup_{i > L} P^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} (L^{N}_{r} > L) & \leq \lim_{N \to \infty} \sup_{i > L} \sum_{i \in S} P^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} (\inf_{t \in [0, T]} |X_{t}^{N,i}| \leq r) \\
& \leq 2 \lim_{N \to \infty} \sup_{i > L} \int_{S} \operatorname{Erf}(\frac{|s| - r}{\sqrt{T}}) d\mu^{N}(ds) \\
& \to 0 \quad (L \to \infty).
\end{align*}

This completes the proof. \hfill \square

**Lemma 4.4.** (12) holds.

**Proof.** (2.17) follows from (4.1, 4.2), and (2.37). For each $i \in \mathbb{N}$ we deduce that
\begin{equation}
\tag{4.12}
E^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} \left[ \int_{0}^{T} \left| b_{r,s,p}^{N}(X_{t}^{N,i}, X_{t}^{N,\pi}) \right|^{p} dt \right] \leq \sum_{i=1}^{N} E^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} \left[ \int_{0}^{T} \left| b_{r,s,p}^{N}(X_{t}^{N,i}, X_{t}^{N,\pi}) \right|^{p} dt \right] \\
= E^{\mu_{t}\circ\hat{N}_{t}^{-1}}_{t} \left[ \sum_{i=1}^{N} \int_{0}^{T} \left| b_{r,s,p}^{N}(X_{t}^{N,i}, X_{t}^{N,\pi}) \right|^{p} dt \right] \\
= E^{\mu_{t}^{N,1}]_{t}}_{t} \left[ \int_{0}^{T} \left| b_{r,s,p}^{N}(X_{t}^{N,1]) \right|^{p} dt \right].
\end{equation}

Diffusion process $X_{t}^{N,1}$ in (4.3) with $m = 1$ given by the Dirichlet form $\mathcal{E}_{t}^{N,1}$ in (4.1) is $\mu_{t}^{N,1}$-symmetric. Hence we see that for all $0 \leq t \leq T$
\begin{equation}
\tag{4.13}
E^{\mu_{t}^{N,1}]}_{t} \left[ \left| b_{r,s,p}^{N}(X_{t}^{N,1}] \right|^{p} \right] \leq \int_{S} \left| b_{r,s,p}^{N} \right|^{p} d\mu_{t}^{N,1}.
\end{equation}

This yields
Lemma 4.5. (I3)–(I5) hold.

Proof. Conditions (2.20), (2.21), and (2.22) follow from (J1), (J2), (I1), (I2), and (2.34). Similarly, as Lemma 4.4, we obtain for each $i \in \mathbb{N}$

\begin{equation}
E^N I \left[ \int_0^T |(b_{r,s}^N) (X_{i}^{N,i}, X_{N}^{N,i})|^\beta dt \right] \leq T \int_{S \times S} |b_{r,s}^N - b_{r,s,p}^N|^\beta d\mu^N \{1\}.
\end{equation}

Hence (2.28) follows from (1.14) and (2.22). (2.24) follows from (3.5) and an inequality similar to (4.14). We have thus obtained (I3). Condition (2.26) follows from (J1) and (J2). Similarly, as Lemma 4.4, we obtain for each $i \in \mathbb{N}$

\begin{equation}
E^N I \left[ \int_0^T |(b_{r,s}^N) (X_{i}^{N,i}, X_{N}^{N,i})|^\beta dt \right] \leq T \int_{S \times S} |b_{r,s}^N - b_{r,s,p}^N|^\beta d\mu^N \{1\}.
\end{equation}

This together with (2.26) implies (2.27). Hence we have (I4). Similarly as Lemma 4.4, we obtain (2.30) from (2.29). We have thus obtained (I5).

Proof of Theorem 2.4. (I1)–(I5) follows from Lemma 4.3–Lemma 4.5. Hence we deduce Theorem 2.4 from Theorem 2.3.

We finally present a sufficient condition of (2.43).

Lemma 4.6. Assume (H1) and (2.45) for each $r \in \mathbb{N}$ as Section 2. We take the label $\ell_N$ as (2.44). Then (2.43) holds.

Proof. Let $c_{12} = 3(N)$ be such that

\begin{equation}
c_{12} = \int_S \operatorname{Erf} \left( \frac{|x| - r}{\sqrt{3}} \right) \rho^N(x) dx.
\end{equation}

Let $c_{13} = \limsup_{N \to \infty} 12(N)$. Then from (H1) and (2.45), we see that for each large $r$

\begin{equation}
c_{13} \leq \lim_{N \to \infty} \int_{S_r} \operatorname{Erf} \left( \frac{|x| - r}{\sqrt{3}} \right) \rho^N(x) dx + \limsup_{N \to \infty} \int_{S \setminus S_r} \operatorname{Erf} \left( \frac{|x| - r}{\sqrt{3}} \right) \rho^N(x) dx < \infty.
\end{equation}

From (H1) we see that $\{\mu_N\}_{N \in \mathbb{N}}$ converges to $\mu$ weakly. Hence $\{\mu_N\}_{N \in \mathbb{N}}$ is tight. This implies that there exists a sequence of increasing sequences of natural numbers $a_n = \{a_n(m)\}_{m=1}^\infty$ such that $a_n < a_{n+1}$ and that for each $m$

\begin{equation}
\lim_{n \to \infty} \limsup_{N \to \infty} \mu^N (s(S_m)) \geq a_n(m) = 0.
\end{equation}

Without loss of generality, we can take $a_n(m) > m$ for all $m, n \in \mathbb{N}$. Then from this, we see that there exists a sequence $\{p(L)\}_{L \in \mathbb{N}}$ converging to $\infty$ such that $p(L) < L$ for all $L \in \mathbb{N}$ and that

\begin{equation}
\lim_{L \to \infty} \limsup_{N \to \infty} \mu^N (s(S_{p(L)})) \geq L = 0.
\end{equation}

Recall that the label $\ell_N(s) = \{s_i\}_{i \in \mathbb{N}}$ satisfies $|s_1| \leq |s_2| \leq \cdots$. Using this, we divide the set $S$ as in such a way that

\begin{align*}
\{s_L \in S_{p(L)}\} \quad \text{and} \quad \{s_L \notin S_{p(L)}\}.
\end{align*}

Then $s \in \{s_L \in S_{p(L)}\}$ if and only if $s(S_{p(L)}) \geq L$. Hence we easily see that

\begin{equation}
\sum_{i > L} \int_S \operatorname{Erf} \left( \frac{|s_i| - r}{\sqrt{3}} \right) \mu^N (ds) \leq 12(N) \mu^N (\{s \in S_{p(L)} \mid s(S_{p(L)}) \geq L\}) + \int_{S \setminus S_{p(L)}} \operatorname{Erf} \left( \frac{|x| - r}{\sqrt{3}} \right) \rho^N(x) dx.
\end{equation}
Taking the limits on both sides, we obtain
\[
\lim_{L \to \infty} \limsup_{N \to \infty} \sum_{i=1}^{N} \int_{S} \text{Erf}\left[\frac{|s| - r}{\sqrt{2L}}\right] \rho_i^N(ds) \leq \\
\lim_{L \to \infty} \limsup_{N \to \infty} \mu^N\{\{s \in S(L) \geq L\} + \lim_{L \to \infty} \limsup_{N \to \infty} \int_{S \setminus S(L)} \text{Erf}\left[\frac{|x| - r}{\sqrt{2L}}\right] \rho_i^{N,1}(x)dx.
\]
Applying (1.10) and (1.11) to the second term, and (2.45) to the third, we deduce (2.43). \qed

5. Examples

The finite-particle approximation in Theorem 2.2 contains many examples such as Airy_2 point processes (β = 1, 2, 4), Bessel_{2,α} point process, the Ginibre point process, the Lennard–Jones 6-12 potential, and Riesz potentials. The first three examples are related to random matrix theory and the interaction Ψ(x) = −log|x|, the logarithmic function. We present these in this section. For this we shall confirm the assumptions in Theorem 2.2 that is, assumptions (H1)–(H4) and (J1)–(J6).

Assumption (H1) is satisfied for the first three examples [13, 29]. As for the last two examples, we assume (H1). We also assume (H2), (H3) can be proved in the same way as given in [25]. In all examples, a is always a unit matrix. Hence it holds that (H4) is satisfied and that (2.32) in (J1) becomes b^N = \frac{1}{2} d^N. From this we see that SDEs (2.47) and (2.39) become
\[
dX_{N,i} = dB_{N,i} + \frac{1}{2} d^N(X_{N,i}, X_{N,j}) dt \quad (1 \leq i \leq N),
\]
\[
dX_i = dB_i + \frac{1}{2} d^d(X_i, X_j) dt \quad (i \in \mathbb{N}),
\]
where d^d is the logarithmic derivative of μ given by (2.38). Assumption (J6) for the first three examples with β = 2 can be proved in the same way as [25] as we explained in Remark 2.4. Thus, in the rest of this section, our task is to check assumptions (J2)–(J5).

5.1. The Airy_β interacting Brownian motion (β = 1, 2, 4). Let μ_{Airy,β} and µ_{Airy,β} be as in Section 1. Recall SDEs (1.10) and (1.11) in Section 1. Let X^N = (X_{N,i})_{i=1}^N and X = (X_i)_{i \in \mathbb{N}} be solutions of
\[
dX_{N,i} = dB_{N,i} + \frac{1}{2} \sum_{j=1, j \neq i}^{N} \frac{1}{X_{N,i} - X_{N,j}} dt - \frac{β}{2}(N^{1/3} + \frac{1}{2N^{1/3}} X_{N,i}) dt,
\]
\[
dX_i = dB_i + \frac{1}{2} \lim_{r \to \infty} \frac{1}{|X_i|} \sum_{|X_j| < r, j \neq i} \frac{1}{X_i - X_j} - \int_{|X| < r} \frac{ϕ(x)}{x} dx dt \quad (i \in \mathbb{N}).
\]

Proposition 5.1. If β = 1, 4, then each sub-sequential limit of solutions X^N of (1.10) satisfies (1.11). If β = 2, then the full sequence converges to (1.11).

Proof. Conditions (J2)–(J5) other than (2.38) can be proved in the same way as given in [26]. In [26], we take χ_\{X_i \geq 1\}(x); its adaptation to the present case is easy.

We consider estimates of correlation functions such that
\[
\inf_{N \in \mathbb{N}} ρ_{Airy,β}^{N,1}(x) \geq c_{14}(r) \quad \text{for all } x \in S_r,
\]
\[
\sup_{N \in \mathbb{N}} ρ_{Airy,β}^{N,2}(x, y) \leq c_{15}(r) \quad \text{for all } x, y \in S_r,
\]
where c_{14}(r) and c_{15}(r) are positive constants. The first estimate is trivial because ρ_{Airy,β}^{N,1} converges to ρ_{Airy,β} uniformly on S_r and, all these correlation functions are continuous and positive. The second estimate follows from the determinantal expression of the correlation functions and bounds on derivative of determinantal kernels. Estimates needed for the proof can be found in [26] and the detail of the proof of (5.3) is left to the reader.
Equation (2.30) follows from (5.3) and (5.4). Indeed, the integral in (2.30) is taken on the bounded domain and the singularity of integral of \( \eta^N(x, y) = \beta/(x - y) \) near \( \{ x = y \} \) is logarithmic. Furthermore, the one-point correlation function \( \rho^{N, 1}_{\text{Airy}, \beta, x} \) of the reduced Palm measure conditioned at \( x \) is controlled by the upper bound of the two-point correlation function and the lower bound of one-point correlation function because

\[
\rho^{N, 1}_{\text{Airy}, \beta, x}(y) = \frac{\rho^{N, 2}_{\text{Airy}, \beta}(x, y)}{\rho^{N, 1}_{\text{Airy}, \beta}(x)}.
\]

Using these facts, we see that (5.3) and (5.4) imply (2.36). □

5.2. The \( \text{Bessel}_{2, \alpha} \) interacting Brownian motion. Let \( S = [0, \infty) \) and \( \alpha \in [1, \infty) \). We consider the \( \text{Bessel}_{2, \alpha} \) point process \( \mu_{\text{bes}, 2, \alpha} \) and their \( N \)-particle version. The \( \text{Bessel}_{2, \alpha} \) point process \( \mu_{\text{bes}, 2, \alpha} \) is a determinantal point process with kernel

\[
K_{\text{bes}, 2, \alpha}(x, y) = J_\alpha(\sqrt{x}J_{\alpha}^*(\sqrt{y})) - \sqrt{x}J_{\alpha}^*(\sqrt{x})J_\alpha(\sqrt{y})
\]

\[
= \frac{\sqrt{x}J_{\alpha+1}(\sqrt{x})J_\alpha(\sqrt{y}) - J_\alpha(\sqrt{x})\sqrt{y}J_{\alpha+1}(\sqrt{y})}{2(x - y)},
\]

where \( J_\alpha \) is the Bessel function of order \( \alpha \) [29, 5]. The density \( m_\alpha^N(x)dx \) of the associated \( N \)-particle systems \( \mu_{\text{bes}, 2, \alpha}^N \) is given by

\[
m_\alpha^N(x) = \frac{1}{Z_\alpha^N} e^{-\sum_{i=1}^N x_i/N} \prod_{j=1}^N x_j^{\alpha} \prod_{k<l} |x_k - x_l|^2.
\]

It is known that \( \mu_{\text{bes}, 2, \alpha}^N \) is also determinantal [29, 945p] and [2, 91p] The \( \text{Bessel}_{2, \alpha} \) interacting Brownian motion is given by the following [2].

\[
\begin{align*}
\text{d}X_{i}^{N,i} &= dB_t^i + \left\{-\frac{1}{8N} + \frac{\alpha}{2X_t^i} + \sum_{j=1,j\neq i}^N \frac{1}{X_{t}^i - X_{t}^j}\right\}dt \quad (1 \leq i \leq N), \\
\text{d}X_t^i &= dB_t^i + \left\{\frac{\alpha}{2X_t^i} + \sum_{j\neq i}^\infty \frac{1}{X_{t}^i - X_{t}^j}\right\}dt \quad (i \in \mathbb{N}).
\end{align*}
\]

This appears at the hard edge of one-dimensional systems.

**Proposition 5.2.** Assume \( \alpha > 1 \). Then (2.48) holds for (5.7) and (5.8).

**Proof.** (J2) - (J5) except (2.43) are proved in [5]. We easily see that the assumptions of Lemma [11] hold and yield (2.43). We thus obtain (J6). □

**Remark 5.1.** There exist other natural ISDEs and \( N \)-particle systems related to the \( \text{Bessel} \) point processes. They are the non-colliding square Bessel processes and their square root. The non-colliding square Bessel processes are reversible to the \( \text{Bessel}_{2, \alpha} \) point processes, but the associated Dirichlet forms are different from the \( \text{Bessel}_{2, \alpha} \) interacting Brownian motion. Indeed, the coefficients \( a^N \) and \( a \) in Section 2 are taken to be \( a^N(x, y) = a(x, y) = 4x \). On the other hand, each square root of the non-colliding Bessel processes is not reversible to the \( \text{Bessel}_{2, \alpha} \) point processes, but has the same type of Dirichlet forms as the \( \text{Bessel}_{2, \alpha} \) interacting Brownian motion. In particular, the coefficients \( a^N \) and \( a \) in Section 2 are taken to be \( a^N(x, y) = a(x, y) = 1 \). That is, they are constant time change of distorted Brownian motion with the standard square field.

We refer to [10, 11, 24] for these processes. For reader’s convenience we provide an ISDE describing the non-colliding square Bessel processes and their square root. We note that SDE
Let $Y^N = (Y^{N,i})_{i=1}^N$ and $Y = (Y^i)_{i \in \mathbb{N}}$ be the non-colliding square Bessel processes. Then for $1 \leq i \leq N$

$$dY^{N,i}_t = \sqrt{Y^{N,i}_t} dB^i_t + 4 \{ - \frac{Y^{N,i}_t}{8N} + \frac{\alpha + 1}{2} + \sum_{j=1, j \neq i}^N \frac{Y^{N,j}_t}{Y^{N,i}_t - Y^{N,j}_t} \} dt,$$

(5.9)

$$dY^i_t = \sqrt{Y^i_t} dB^i_t + 4 \{ - \frac{Y^i_t}{8N} + \frac{\alpha + 1}{2} + \sum_{j=1, j \neq i}^\infty \frac{Y^j_t}{Y^i_t - Y^j_t} \} dt \quad (i \in \mathbb{N}).$$

(5.10)

Let $Z^N = (Z^{N,i})_{i=1}^N$ and $Z = (Z^i)_{i \in \mathbb{N}}$ be square root of the non-colliding square Bessel processes. Then applying Itô formula we obtain from (5.9) and (5.10)

$$dZ^{N,i}_t = dB^i_t + \{ - \frac{Z^{N,i}_t}{4N} + \frac{\alpha + 1}{2} \} \sum_{j=1, j \neq i}^N \frac{2Z^{N,j}_t}{(Z^{N,i}_t)^2 - (Z^{N,j}_t)^2} dt \quad (1 \leq i \leq N),$$

(5.11)

$$dZ^i_t = dB^i_t + \{ \frac{\alpha + 1}{2} \} \sum_{j \neq i}^\infty \frac{2Z^j_t}{(Z^i_t)^2 - (Z^j_t)^2} dt \quad (i \in \mathbb{N}).$$

(5.12)

We remark that Theorem 2.2 can be applied to the non-colliding square Bessel processes because the equilibrium states are the same as the Bessel interacting Brownian motion and coefficients are well-behaved as $a^N(x,y) = a(x,y) = 4x$.

### 5.3. The Ginibre interacting Brownian motion

Let $S = \mathbb{R}^2$. Let $\mu_{\text{gin}}^N$ and $\mu_{\text{gin}}$ be as in Section 1. Let $\Phi^N = |x|^2$ and $\Psi(x) = - \log |x|$. Then the $N$-particle systems are given by

$$dX^{N,i}_t = dB^i_t - X^{N,i}_t dt + \sum_{j=1, j \neq i}^N \frac{X^{N,i}_t - X^{N,j}_t}{|X^{N,i}_t - X^{N,j}_t|^2} dt \quad (1 \leq i \leq N).$$

(5.13)

The limit ISDEs are

$$dX^i_t = dB^i_t + \lim_{r \to \infty} \sum_{|X^i_t - X^j_t| < r, j \neq i} \frac{X^i_t - X^j_t}{|X^i_t - X^j_t|^2} dt \quad (i \in \mathbb{N})$$

(6.12)

and

$$dX^i_t = dB^i_t - X^i_t dt + \lim_{r \to \infty} \sum_{|X^i_t - X^j_t| < r, j \neq i} \frac{X^i_t - X^j_t}{|X^i_t - X^j_t|^2} dt \quad (i \in \mathbb{N}).$$

(6.13)

### Proposition 5.3. (2.48) holds for (6.12) and both (6.13) and (6.14).

**Proof.** (J2)–(J5) except (2.43) are proved in [20]. [24] (2.43) is obvious for a Ginibre point process because their one-correlation functions with respect to the Lebesgue measure have a uniform bound such that $p_{\text{gin}}^{N,1} \leq 1/\pi$. This estimate follows from (6.4) in [19] immediately. Let $d_1$ and $d_2$ be the logarithmic derivative associated with ISDEs (6.13) and (6.14). Then $d_1 = d_2$ a.s. [19]. Hence we conclude Proposition 5.3. \qed

### 5.4. Gibbs measures with Ruelle-class potentials

Let $\mu^R$ be Gibbs measures with Ruelle-class potential $\Psi(x,y) = \Psi(x-y)$ that are smooth outside the origin. Let $\Phi^N \in C^\infty(S)$ be a confining potential for the $N$-particle system. We assume that the correlation functions of $\mu^{\Phi^N,\Psi}$ satisfy bounds $\sup_N \rho^{N,m} \leq c_{16}$ for some constants $c_{16}$; see the construction of [25]. Then one can see in the same fashion as [25] that $\mu^R$ satisfy (J2)–(J5) except (2.43). Under the condition $\sup_N \rho^{N,m} \leq c_{16}^m$ (2.13) is obvious. Moreover, if $\mu^R$ is a grand canonical Gibbs measure with sufficiently small inverse temperature $\beta$, then $\mu^R$ is tail trivial. Hence we can obtain (J6) in the same way as [24] in this case. We present two concrete examples below.
5.4.1. Lennard–Jones 6-12 potentials. Let $S = \mathbb{R}^3$ and $\beta > 0$. Let $\Psi_{6-12}(x) = |x|^{-12} - |x|^{-6}$ be the Lennard-Jones potential. The corresponding ISDEs are given by the following.

$$dX_i^N = dB_i^j + \frac{\beta}{2} \left( \nabla \Phi^N(x_i^N) + \sum_{j=1, j \neq i}^{N} \frac{12(X_i^N - X_j^N)}{|X_i^N - X_j^N|^4} - \frac{6(X_i^N - X_j^N)}{|X_i^N - X_j^N|^8} \right) dt \quad (1 \leq i \leq N),$$

$$dX_i^1 = dB_i^j + \frac{\beta}{2} \sum_{j=1, j \neq i}^{\infty} \left( \frac{12(X_i^1 - X_j^1)}{|X_i^1 - X_j^1|^4} - \frac{6(X_i^1 - X_j^1)}{|X_i^1 - X_j^1|^8} \right) dt \quad (i \in \mathbb{N}).$$

5.4.2. Riesz potentials. Let $d < a \in \mathbb{N}$ and $\beta > 0$. Let $\Psi_a(x) = \frac{\beta}{a} |x|^{-\alpha}$ the Riesz potential. The corresponding SDEs are given by

$$dX_i^N = dB_i^j + \frac{\beta}{2} \left( \nabla \Phi^N(x_i^N) + \sum_{j=1, j \neq i}^{N} \frac{X_i^N - X_j^N}{|X_i^N - X_j^N|^{2+a}} \right) dt \quad (1 \leq i \leq N),$$

$$dX_i^1 = dB_i^j + \frac{\beta}{2} \sum_{j=1, j \neq i}^{\infty} \frac{X_i^1 - X_j^1}{|X_i^1 - X_j^1|^{2+a}} dt \quad (i \in \mathbb{N}).$$
